At this stage he would remind them of the tremendous leg-up which the alternating transformer system had received from Mr. Westinghouse. Westinghouse was one of the most wonderful men in the world. There was no man like him as an organizer of labour and as an organizer of machinery. Witness his brake. In the face of the most tremendous opposition from the railway authorities, he had made his brake almost universal, and he had done that with all those peculiar powers. He was a very rich man and he had unparalleled facilities at the town of Pittsburgh, where his most successful lighting had been carried out. But he would tell them that what Westinghouse had done for the transformer system was exactly what Brush did for arc lighting when they used arc lighting—they might say for the first time—in England a few years ago. He had turned out from a well-appointed factory complete, well-considered sets of machinery, packed and sent away to any township in America that wanted electric light of a sort. It could be put up in the way that American electric lighting machinery was done—very roughly—on the spot. But the things were so well appointed and so well made in the factory that they could be erected at small cost, and in sufficiently good rough-and-ready fashion to suit the American taste. Anybody who had been in America, anybody who knew anything about American installations, would confirm what he was saying—that electric lighting machinery in America as made in the shops was perfection, but the putting of it up was such as would not pass muster in the worst of our English installations. That had been the case with the enormous list of transformer machinery that had been carried out by Mr. Westinghouse. Although that was perfectly suited for such countries as America and Australia, countries where rough workmanship and such things did, it was quite unsuited for civilized countries. The alternate-current transformer was well suited for such cases, but the moment they brought it into London, the moment that it was no longer a revel, as it was at present, over the tops of the houses, the moment they confined it under the streets, then it lost all its advantages. What were its advantages? Its advantages were that they could put down a station, and they could run wires anywhere they pleased, on account of the peculiar state of the law, and take up a number of customers that otherwise they could not reach at all. But he said that when the taste for electric lighting became more universal, when two in every three people along the line of streets took the light—that such a system of overhead mains and that kind of thing was intolerable, and there must come the day when mains had to be laid, as they had been successfully laid under the streets, and then they would find that the alternate transformer system was out of it as compared with the other. He was glad to see that Mr. Kapp, in his paper, practically admitted that. He admitted it in his last sentence, and a man puts his sense in the last sentence of his paper. The fact of the matter was, when Mr. Kapp said they would have to lay down a network, and when Mr. Mackenzie said they would have to lay down a network, he would like to know in what way they would lay down a network cheaper than the batteries. The mains could be laid in the streets from 14s. at the lowest to 16s. or 18s. a yard at the highest. The smallest section of copper could not be put in under 14s., and 16s. or 18s. would give them a very fair section of copper quite sufficient for an ordinary length of streets. When people talked of copper as if copper were the only thing that had to do with the cost of conduction, they were talking nonsense. This was not the place to go into a long comparative estimate as to the cost of the two systems; suffice it to say, he had figures in his possession that he had worked out very carefully. He would not take the extreme figures mentioned by Mr. Mackenzie, who assumed 100 volts and transmitted it through an inch and a half cable with 1,500 amperes at 100 volts potential. By taking 500 volts, which was workable for a distance where the generating station was situated from a mile to two miles from the centre of the district to be supplied, the cost of the two systems worked out practically identical. That was to say, if 10,000 lights had to be supplied in a town, with the generating station situated not more than two miles from the centre of the supply, the cost of those 10,000 lights—and he called the maximum number at one time 10,000 lights—the cost was identical in the two cases, and there was no saving by using the alternate system. Now he would attack the alternating system as an efficient one. They had heard a lot about the efficiency of transformers. There had been a fight over a few places of decimals. That was whether they were 80 or 90 per cent. They had got efficiencies showing that at a very low heat indeed the true efficiency was as high as 80 per cent. of the transformer, and he did not believe that. The large transformers that would have to be large enough to go up to the peak of the diagram shown by Mr. Gordon, but when they were working in the daytime, they would not be working at much more than 15 to 20 per cent efficiency. Further than that, those transformers were worked by very large dynamos. Mr. Mackenzie talked about 42½ 5,000 horse-power dynamos, and they were told that the total size of the station was 20,000 horse-power. He would like to know how many tons of coal per lamp (laughter) it would take to work these lamps at the day time. He had made some experiments in this

direction, and he knew from experience in years gone by, and from other experience, what it meant to run engines even with continuous currents, without the aid of batteries, i.e., to run them nearly empty. There was not a more extravagant beast on the face of the earth than a compressed or triple expansion engine worked down to a fourth or a fifth of its full output. As Mr. Gordon said, the two other cylinders were nothing more nor less than air pumps—drags on the engine—and Mr. Williams could tell them a great deal better than he could what they would do. They might put it in this way—These big engines used about two-thirds of the coal when empty that they did when full—that is to say, if using 20 tons a day when full, when they were running one lamp they would be using about thirteen or fourteen. So they could see what it came to. Everybody who worked central stations knew these facts. Mr. Mackenzie knew them. He knew how much coal they were burning now at the Grosvenor Gallery, and he Mr. Crompton knew, and he could tell them they were burning five times as much coal at the Grosvenor Gallery, lamp for lamp, as he burnt at Vienna. That was because he employed accumulators, and these were wasting their coal by having to keep an engine running for long hours when there were very few lamps on. If Sir Coutts Lindsay had asked him to put up a battery system about two years ago, Sir Coutts would have saved enough money in his coal bill from the time he started to pay for two new batteries. Mr. Gordon's diagram was almost an exact copy of half a dozen diagrams that had been shown to himself this evening by Dr. Fleming, which had come from the Edison Company in America, and referred to various installations. That diagram of Mr. Gordon's, which he knew was founded on London experience, was almost a correlation of work that he had done at Vienna, and it was exactly corroborated by those most interesting diagrams that Dr. Fleming had got, which pointed out that there were peaks for only an hour or a couple of hours' duration, when the demand was nearly double that of the other maximum demand he meant by the latter the demand that lasted for three or four hours—and something like ten or twelve times the average demand. He thought the whole path of the economical question lay in studying diagrams of this kind. The whole thing was turning on the one question that was raised by Mr. Mackenzie. Mr. Mackenzie had this in doubt on the question, which had been over and over again asserted, that they could not run alternate current machines in parallel. If they could run them parallel, that would knock the bottom out of a great many of his Mr. Crompton's arguments. There was no doubt about that. But it had not yet been done—he had taken very great pains to find out whether it had been done in practice—but it certainly had not been done here in England, and it had not been done in America otherwise than experimentally. When these gentlemen could use them so that they could know the lines he did of putting one dynamo on after another and working them up to their full capacity and their best efficiency as the demand arose and fill up the sharp angles between the dynamos by working accumulators in parallel to them, and these gentlemen could do that they would never approach the efficiency that he had at present. He believed from Mr. Mackenzie's statements and from all the rest, he could hear that Signor Forzani had virtually admitted that they could not put the machines parallel by his desires to construct these gigantic machines that were mentioned in the paper.

(To be continued.)

COMPANIES' MEETINGS.

THE PILSEN-JOEL ELECTRIC LIGHT COMPANY.

An extraordinary general meeting of the shareholders in this Company was held on Tuesday at the Cannon street Hotel.

Mr. E. W. Rawson, who presided, proposed: "That if an order of the Court be obtained for confirming this resolution, the capital of the Company be reduced as follows:—(a) By reducing from £2 to £1 per share the nominal amount of the 3,517 shares of the Company of £2 each which have been forfeited, and are now unissued. By cancelling, as being capital which has been lost, or is represented by available assets, the sum of £1 per share on the 24,483 shares of the Company of £2 each, with £1.5s. called up thereon, being the shares numbered 1 to 23,000 inclusive, with the exception of those mentioned above in Clause (c), and the sum of £1.16s. per share on the fully paid-up shares of £2.5s. each, being the shares numbered 39,351 to 39,450 inclusive. And that the memorandum of association of the Company be modified, so as to carry into effect this resolution."

The **Chairman** having explained the object of the resolution, **Mr. Fyfe** severely criticised the whole of the proceedings, and informed the shareholders that two of the directors, Major Scriven and Mr. Whately, were disqualified, because they had not a sufficient number of shares. This statement caused considerable disorder, but it was generally accepted by the shareholders.

Mr. Samuel, in strong terms, alluded to the whole of the proceedings as illegal.

The **Solicitor** was asked whether Mr. Fyfe's remarks were authentic, and in answer he stated that they were. The directors were therefore no longer qualified for their office.

Mr. Fyfe then proposed, and **Mr. Hutton** seconded, an amendment for the adjournment of the meeting for a month, and that a committee of shareholders be appointed to investigate the statement contained in the notice convening the meeting, to confer with the chairman and late directors, and to report thereon, and generally upon the business of the Company at such adjourned meeting, and in the meantime the chairman and secretary be authorised to continue the business.

The resolution was unanimously agreed to.

PROVISIONAL PATENTS, 1888.

MARCH 2.

3215. Improvements in electric incandescent lamps. John William Oldroyd, 8, Quality-court, London, W.C. (Complete specification).
3223. Improvements in secondary batteries. William Kingsland, 49, Cambridge-road, Gunnersbury, W.
3230. Improvements in electrical tramways and railways. Frederick Charles Allsup, Bealey, Kent.
3235. Improvements in multipolar dynamo-electric machines. George Miot, 46, Lincoln's Inn-fields, London, W.C.

MARCH 3.

3286. Improvements in electrical measuring instruments. George Leonard Adlenbrooke, 9, Mecklenburgh-street, W.C.
3303. Improved apparatus for registering the consumption of electric energy. Henry Harrington Leigh, 22 Southampton-buildings, Chancery-lane, W.C. Jean Louis Clerc, Paris.
3312. An improvement in voltaic batteries. Edward Tyet, 28, Southampton-buildings, Chancery-lane, London, W.C.
3328. Improvements in electric contact makers and commutators. Charles Langdon Davies, 110, Cannon street, London.

MARCH 5.

3359. Improvements in apparatus for operating or controlling type-setting machines, type-writers, and the like by the aid of electricity. Edward Fitzgerald Law, 45, Southampton-buildings, London, W.C.
3369. Improvements in the treatment of zinc and its ores. Alexander Watt, 6, Brown's buildings, Chancery-lane.
3371. An improved method of attaching the caps, or covers of electrical fittings to their bases so as to form an air-tight joint. Charles Cross Falkenstein and Samuel Sudworth, 23, Audalus-road, Clapham, S.W.

MARCH 6.

3456. Improvements in electric bells or ringing apparatus. William Howard Winnall, 4, South-street, Finsbury, London.

MARCH 7.

3483. Improvements in electrical switches. Frederick Thomas Schmitt, Sutcliffe Chambers, Bradford, York-shire. (Complete specification)
3498. Improvements in and relating to alternating current dynamo-electric machines. Thomas Parker, 70, Market-street, Manchester.
3504. Multiple electric communication. James Oldfield, 30, York street, Westminster, London.
3517. Improvements in primary batteries. Robert Disher, 1, Quality-court, W.C.
3535. Improvements in electric conductors. William Bowers Fitch, 4, South street, Finsbury, London.

MARCH 8.

3560. An electrical regenerative battery. Northcote George Thompson, 4, Queen Victoria street, London, E.C.
3571. Improvements in telephonic transmitters. Thomas Laurie, 115 St. Vincent-street, Glasgow.
3590. Improvements in electrical transformers and plates therefor. John Grace Statter, Norfolk House, Norfolk-street, London, W.C.
3593. Improvements in the construction of cells or jars of electric batteries. Robert Walker, 39, Delorme-street, Fulham, S.W., Middlesex.
3614. Improvements in dynamo-electrical machines. Sebastian Ziani de Ferranti, 24, Southampton-buildings, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MARCH 1, 1887.

3158. Improvements in machines for giving currents of electricity on the insertion of a coin, token, or the like. Percival Everett, 4, South-street, Finsbury, London.

MARCH 23, 1887.

4569. Improvements in instruments for detecting and measuring electric currents. Philip John, 35, Narrow Wine street, Bristol.

APRIL 6, 1887.

5140. Improvements in galvanic batteries. William Henry Quarterman, 21, Cockspur street, London, S.W.

APRIL 7, 1887.

5195. Improvements relating to a system of generation and distribution of electricity. George Annesley Grindler, 79, Cambridge gardens, Notting Hill, W.

APRIL 29, 1887.

6267. Lock switches for use in electric circuits. Arthur Cecil G. Alburn and Eustace Thomas, 26, Petherbert-road, Canonbury, N.

MAY 5, 1887.

6590. An improved magneto electric cut-out. William Harding Scott and Edward Alexandre Paris, 1, Queen Victoria street, London, E.C.
6621. An improvement in electro-motors. Joseph Deynport Emney Andrews, 28, Southampton-buildings, Chancery-lane, London, W.C.

MAY 25, 1887.

7548. Improved method of transmission through submarine cables and apparatus therefor. John Gott, 3, Church-court, Old Jewry, E.C.
7611. Improvements in submarine cable grapnels, grapnel rope couplings and connections. Walter Charles Johnson and Samuel Edmund Phillips, 28, Southampton-buildings, Chancery-lane, London, W.C.

MAY 26, 1887.

7675. An improvement in mushroom anchors. Walter Charles Johnson and Samuel Edmund Phillips, 28, Southampton-buildings, Chancery-lane, London, W.C.

OCTOBER 4, 1887.

- 13,447. Improvements in electric railways and tramways. Alexander Logan Lamb and Edward Hodson Bayley, 6, Dream's buildings, E.C.

SPECIFICATIONS PUBLISHED.

1887.

3225. Generating and distributing electric energy. &c. R. Dick and R. Kennedy. 8d.
4322. Dynamo electric machines. J. and E. Hopkinson. 11d.
4472. Electro-deposition of cobalt. S. P. Thompson. 6d.
4978. Holder and switch for electric lamps. F. T. Schmitt. 8d.
4980. Making and breaking electrical circuits. F. T. Schmitt. 8d.
5005. Secondary batteries. J. T. Armstrong. 6d.
5092. Switches for electrical purposes. R. Egger. 8d.
5228. Holders for incandescent electric lamps. W. H. Bayley. 8d.
5707. Automatic cut-outs for electric arc lamps. E. F. H. H. Lambert and H. W. Kingston. 8d.
6972. Obtaining derived currents of variable intensity from a main electric current. J. C. Meebuhl. La Société Anonyme pour la Transmission de la Force par l'Electricité. 8d.

1886.

1235. Incandescence gas lights. C. Von Bach. 8d.

CITY NOTES.

Brazilian Submarine Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending March 9 amounted to £3,668.

Brazilian Submarine Telegraph Company. The investors of this company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, payable on the 24th inst.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ending March 9, after deducting the "fifth" of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, were £3,881.

Alfred Slater and Co. Limited.—The usual notice has been given in the *Gazette* for creditors to send in their claims to the official liquidator, Frank Day, at 45, Tabernacle street, Finsbury-square, on or before the 4th day of April. The place and day fixed for hearing and adjudicating upon the debts and claims is at the Chambers of Mr. Justice Kay, at the Royal Courts of Justice, on Wednesday, the 11th April, at 12.

Direct Spanish Telegraph Company. The Directors of the Direct Spanish Telegraph Company upon the accounts for the half year ending December 31, 1887, being submitted to them, decided, subject to their being audited, to recommend the payment of a dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend of 2½ per cent. free of income tax, for the half year upon the ordinary shares, making with the previous distribution, 4 per cent. per annum for the year 1887.

Eastern Extension Co.—The Eastern Extension, Australasia and China Telegraph Company Limited, announce that their account to December 31 and show subject to audit a balance of profit of £121,800, after payment of three interim dividends. The directors now propose to distribute on April 26 the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1887. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. for the past year, against 6 per cent. in 1886. The balance of £53,000 has been carried to the reserve fund, which now stands at £620,000.

NEW ELECTRICAL COMPANIES.

The St. James's and Pall Mall Electric Light Company (Limited). Registered by Trinders and Co. 47, Cornhill, London, E.C. Capital £100,000, divided into 19,990 ordinary shares of £5 each, and 100 founders' shares of £1 each. The founders' shares shall confer on the holders thereof the right to one-half the net profits of the Company made in each year which shall remain after paying or providing for the payment of a dividend of 7 per cent. for each year on the capital paid up on the other shares. Object: to erect a central station or stations for generating, producing, storing and supply of electricity, electrical motive force or similar agency for lighting, heating and motive purposes, or otherwise, in the district of St. James's and elsewhere throughout the metropolis. The first subscribers are:—

George Edward Francis, retired colonel, 55, Victoria street, S.W. 1
 Latimer Clark, civil engineer, 6, Westminster Chambers, Victoria-
 street, S.W. 1
 Ernest Edmund Molyneux Roys, gentleman, Broadview, Peters-
 field, Hants 1
 Peter Penn Gaskell, justice of the peace, 12, Albert-mansions, S.W. 1
 Edward Matthew Palliser, retired captain, 91, Earl's Court-road 1
 Arnold Trinder, solicitor, 47, Cornhill 1
 Eustace Jeanie Anthony Balfour, architect, 32, Addison-road, Ken-
 sington, W. 1

The number of directors shall not be less than three, nor more than eight, unless otherwise directed at any time by the Company in general meeting. The first directors shall be Eustace J. A. Balfour, Latimer Clark, P. Penn Gaskell, Ernest Molyneux Roys, and Colonel G. E. Francis. The qualification of a director shall be the holding of not less than 100 shares of £5 each, or any equivalent amount of other shares in his own right. The annual remuneration of the directors (exclusive of any managing director) shall be £1,000 per annum, or such larger sum as may be equal to 10 per cent. of the net profits, but such remuneration shall not exceed £1,500 in any year.

Charles L. Baker and Company (Limited). Registered by Rowley and Co. 3, Great Winchester street, E.C., with a capital of £25,000. Object: to acquire on the terms of a provisional agreement dated the 19th of November, 1887 and made between Chas. L. Baker of the one part and Frederick Margatroyd of the other part, with such modifications as may be agreed to by the directors of the Company, may fit the business of Charles L. Baker and Co. telegraphic electric, signals and sound apparatus makers, of Wordsley street, Chester-road, Manchester, as a going concern, including or together with the goodwill of the said business, the right to use the style of the said firm, and all trademarks used in the said business and the benefit of all pending contracts entered into by the said firm, and the lease of the premises

in Wordsley street aforesaid, occupied by the said firm, and all patent rights, plant, utensils, stock in trade, work in progress, patterns, drawings, electric, fittings and effects owned by or belonging to the said firm in connection with the business. The first subscribers are:—

C. Baker, Cornbrook Telegraph Works, Manchester 1
 J. Johnson Bennett, Seymour-grove, Manchester 1
 G. W. Lock, 2, Brooklyn villas, Old Trafford, Manchester 1
 T. Pilling, 2, Booth street, Manchester 1
 F. Margatroyd, 2, Booth street, Manchester 1
 W. Pennman, 6, St. Bees street, Manchester 1
 J. Witham, 72, Bury Old-road, Manchester 1

The first directors shall be James Leigh, J. E. Longson, Thomas Horsfield, W. B. Lowcock, Charles Saeré, John Hugh Pennman, John Knowles Glazebrook, and Charles Laurence Baker. Qualification, the holding by each of at least 250 shares in the Company in his own right. Charles Laurence Baker shall be managing director at a salary of £500 per annum.

Exeter Electric Light Company.—A company has been registered under this title, with a capital of £20,000 in 2,000 shares of £10 each, the first ten of which will be Founder's shares. The prospectus states that nearly one-half of the share capital has been already assured. The directors are:—

William Horton Ellis, J.P. (chairman), Hartwell House, Exeter.
 Laurence J. Kennaway, Homefield, Exeter.
 Walter Pring, J.P., Northlands, Exeter.
 C. J. B. Sanders, Crescent House, Pennsylvania, Exeter.
 G. F. Truscott, Basing Crescent, Exeter.

Henry George Massingham, Taunton Electric Lighting Company (Limited), managing director; will join the Board after allotment.

The Company is formed for the purpose of supplying electricity, both as a light and motive power, to Exeter. The Company has secured the right to use the water-power at Trusworthy to the extent of 100 effective horse-power in perpetuity, at a price which according to the prospectus will be a great saving over the cost of steam power. The public meeting, as we have already intimated, some weeks ago declared in favour of the electric light and a memorial in course of signature, and has already been signed by over 3,000 citizens for presentation to the Town Hall. Over 170 citizens have expressed their willingness to adopt the electric light in their houses and places of business. The system which it is proposed to adopt is that of the Thomson, Houston, and the work will be carried out by Messrs. Laing, Wharton, and Dunn.

NOTES.

Cable Repaired. The Eastern Telegraph Company announce that the Perim Suakin cable is repaired and communication with Suakin restored.

Senegal. The electric light is about to be established at St. Louis, in Senegal, and the plant required for this installation has recently been forwarded from Bordeaux.

Windmills. It will be found that one of the first persons, if not the first, to use windmills as the motive power for driving dynamos to charge batteries was Prof. Bixler of Glasgow. Much has been made of certain French experiments, but surely there is nothing novel in such a proceeding.

Prestbury.—The Committee, at the last meeting of the highway board, recommended that the Lancashire and Cheshire Telephone Company be permitted to erect the necessary posts for their line between Adlington and Lynton, on payment of 1s. per post per year. The Board agreed to this, and ordered the common seal of the Board to be affixed to the agreement.

Switzerland.—The electric tramway at Vevey-Montreux was successfully worked for the first time on the 5th ult., over a length of 11 kilometres. The Montreux station will supply the electric light throughout the neighbourhood, by means of alternating current machines and transformers. Some of the subscribers have had the light in their houses for several weeks past.

A Long Lamp Life. Mr. Gilbert Wilkes, Ensign U.S. Navy, referring to the statement that a certain incandescence lamp had been maintained in action for the long period of 5,292 hours, testifies that when the U.S.S. "Trenton" returned from China in 1886, one Edison lamp, of which, together with many others, a very careful record was kept, had burned 9,700 hours, and was still in good condition.

Electric Railway. As stated last week, M. Fischer, a Viennese engineer, has obtained the concession for an electrical railway between Voslau, near Baden, and Leopoldsdorf, a distance of 27 kilometres. We are further informed that the line is to be worked by means of accumulators, and that, with a view of securing the best for the purpose, comparative trials are about to be made of the E.P.S. and the Julien batteries.

Electric Bells.—An interesting popular lecture on these useful appliances was recently delivered by Prof. Sylvanus Thompson, at the Royal Victoria Hall. The construction and use of the vibrating armature, and the source of the energy expended in working the apparatus, were made quite clear to the audience; the subject being illustrated by a number of experiments.

Australia. The electric lighting of the Adelaide Exhibition comprises 144 arc and 266 incandescence lamps. The former are worked by 11 Brush dynamos, 10 of which are of 8,000 and 1 of 6,000 watts. The incandescence lamps are worked by 3 Victoria dynamos of 8,000 watts each, an Edison-Hopkinson machine of 8,000 watts, and an Edison dynamo of 5,000 watts. The total length of the cables for conveying the current is 8 miles.

Electrical Tramways.—The paper on "the Bessbrook and Newry Tramway," by Dr. E. Hopkinson, recently read before the Institution of Civil Engineers, has just been

issued by the Institution in pamphlet form. The paper is perhaps the most exhaustive that has been given on the subject of electrical tramways in England, and, with the discussion thereon, contains a vast amount of information of interest to all engaged in light or street tramway work.

Traction.—The new tramway at Ansonia, Conn., is expected to be ready immediately. It will have one 60 h.p. motor to pull goods, and four 15 h.p. motors to haul the passenger cars. It is claimed that this is one of the best equipped electric roads in America. The Ontario and San Antonio Heights road is well advanced. Here the third-rail system is adopted. The lines are laid with 30lb steel rails. The running will commence with four cars and three motors.

The Electro-Harmonic Society.—The last smoking concert of the season 1887-1888 will take place at the usual *rendezvous* on Friday evening, April 6th. An innovation in entertainments of the kind will be made, a string quartette, performing works of Mozart and Haydn, taking the place of the usual glee party. Violin duets, which some decades since were so fashionable, but which are now rarely heard, will also be played, and the vocal element will be ably sustained by Messrs. Arthur Thompson and Robert Hilton and Master Humm.

The Defective Lewis Cable.—Arrangements have now been made for carrying on telegraph communication between the island of Lewis and the mainland by means of the cable across the Minch, which has for several days been in a defective state. Two clerks from the Inverness office have been sent to Poolewe, where the cable joins the mainland, and by tapping the wire there they have established a temporary telegraph station, from which the messages are retransmitted to their destination. A cable ship will, it is understood, be at once sent to repair the damage.

Electrical Quackery. A circular with which one of our friends has obliged us, says *l'Electron*, announces an important discovery made by Mme. V. L. According to this philanthropic inventor, invalids may in all cases be restored to health by the use of "*Dynamo-Electric Water*" applied as a lotion, or for fomentations, or in the form of a bath; and it will be found more efficacious than the most celebrated mineral waters. As our contemporary observes, there are not only big charlatans but little ones in the electrical field, without counting those in petticoats, like Mme. V. L.

Currents under Gaseous Pressure.—M. Cailletet, whose name is so well known in connection with the liquefaction of gases, and who has recently devised an apparatus for heating substances by electricity under high gaseous pressure, has pointed out that a current which would ordinarily fuse a given wire or sheet of platinum produces only a temperature rising to dull redness when the gaseous pressure is sufficiently high. It has also been shown by the same experimenter that this phenomenon is due to convection, since the temperature is greatly augmented by surrounding the heated body by a glass test tube which prevents the movement of the gas.

Paris Theatres. The lighting by electricity of the ill-fated Opera Comique was commenced on the 15th inst., a trial of the exterior lamps having been made during the two previous days. The installation at present comprises 503 incandescence lamps, exclusive of those which are now being supplied to that portion of the building which is

behind the footlights. The current is supplied from the machines established in the Châtelet by the *Société d'Éclairage Électrique*.—The electric lighting of the Odéon Theatre, carried out by the Edison Company, was inaugurated on the 20th inst. It comprises 1,200 incandescence lamps, worked by three dynamos each capable of maintaining 500 lamps.

Another Theatre Burned Down through Gas.—Another catastrophe, comparing in horror with that at the Paris Opéra Comique, is announced from Oporto. The Baquet Theatre in that town was completely destroyed by fire on the night of the 20th inst.; the conflagration being caused by a gas accident which occurred during the last act of the piece in representation. Unfortunately, there was a very full house at the time, and it is feared that nearly all the occupants of the upper gallery lost their lives. The number of persons ascertained by the police to be missing was given on Wednesday evening as forty; but the number of those who perished is, we regret to say, probably very much greater.

Electrical Images.—The phenomenon, first observed by M. Karsten, which occurs when, for instance, a piece of glass separates a sheet of tin foil and a coin, and the metals are connected to a frictional machine in action, is tolerably well known. A very perfect and delicate image of the face of the coin is obtained when the glass is breathed upon. In repeating this experiment, M. Tschichowitch made the curious observation that the image thus obtained may readily be fixed by slightly moistening the glass with a weak solution of stearine, oxide of zinc, or yellow oxide of mercury in benzine. It was also observed that a very distinct image was obtained by coating the glass in the first instance with a very slight layer of vaseline or of a fatty substance; the appearance of the coin is very satisfactorily reproduced on this layer.

American Testimony.—There is no doubt, says Mr. Johnson, President of the Lafayette-street Railway, but that electric motors will soon take the place of our "horse motors." The best field for the promoters of electric roads is new roads, as we who have horses know something of the cost of daily running, while all the statements that I have ever seen state the cost of horse-power away above what it is. The different electric motor companies do not guarantee anything as to daily cost, and you can't hold them down to an estimate for average days. Until they will meet this demand of the street car companies I think the "changing" will "make haste slowly." According to the testimony of the North Metropolitan Tramway Company, that Company has a guaranteed contract for electric traction at 4½d. per mile.

Incandescence Filaments.—An American contemporary points out that the filaments of high resistance lamps afford a good illustration of the effects of elasticity. Surrounded by a vacuum, so as to be free from the damping effects of the air, no object more sensitive to vibrations or shocks can be found. The least tremor of the wall to which the lamps are attached makes the loop vibrate for a long period. This only takes place when they are cold. When the current is passing and they become red or white hot, they are no longer so elastic, and cannot be made to vibrate as before. It would seem possible that a visual seismograph of extreme sensitiveness could be made on the general lines of an incandescent burner. It is probable that a filament could be obtained in this way more affected

by external vibrations than is the most sensitive diaphragm now used.

Vibrating Strings.—Herr J. Puluj, of Vienna, devised an extremely ingenious method of rendering visible the form of a stretched string set in vibration. One extremity is attached to the prong of a tuning-fork, which is kept in motion by an electro-magnet contact bell, and which gives a definite note, the pitch of which is fully determined. The vibrating string is lighted up in a vacuum tube connected with a Ruhmkorff coil, the discharge through the tube being alterable at will, and this is made equal to or some aliquot multiple of the number of vibrations made by the string, the latter is illuminated when occupying some one definite position, owing to the persistence of its image on the retina, it appears as if at rest. In this way the form assumed by the string and the positions of the nodes and ventral segments are rendered clearly visible.

Electrical Barometer.—*L'Electricien* gives a description of an electrical barometer devised by M. Renning, in which there is a cylinder, inscribed with the more conventional indications: Much Rain, Rain, Change, &c. moved by clockwork which is brought into operation by electric currents from the "dry pile" of Dr. Crookes. These currents, as most of our readers will understand without further description, affect the cylinder, the intermediary of an electro-magnet, whenever electrical contacts are established by the movement of the needle of an aneroid barometer. It seems to us that M. Renning's invention, supposing it to have preceded the ordinary arrangement, might have been greatly improved and simplified by directly utilising the needle as a pointer. This very negative praise would not apply, however, in cases where it might be necessary to show the indication at a distance from the instrument.

The Steam Electro Magnet.—Many of our readers like ourselves, may have been under the impression that—whatever be the explanation of the fact—iron becomes magnetised, in some degree, when a current of steam is caused to traverse with great velocity a tube of copper, wound helically upon its core. The experimental result in question was obtained, we understood, by M. Tommasi, and his result was subsequently confirmed by M. Thouvenot. A correspondent of *L'Electricien* now states that he has repeated the experiment with an entirely negative result, even at higher steam pressures than had been mentioned as necessary. Messrs. Tommasi and Thouvenot have, under the circumstances, been requested to render assistance in explanation; and the Editor of the above-named paper is about to repeat the experiment for the satisfaction of those who are interested in the question.

Private Press Wires.—For some years past the proprietors of the *Manchester Evening News* have been endeavouring to induce the Post Office authorities to grant the use of a private wire between Manchester and London. This has been persistently refused until recently, but the Post Office people have given way, and the paper has witnessed the commencement of a scheme which is to practically revolutionise the evening newspaper of the United Kingdom. The whole of the Parliamentary intelligence and other matters will be sent through private wire direct, instead of having to await the convenience of the public service, and events of supreme importance to the community will be known and circulated

chester as quickly as in London itself. Only journalists can appreciate fully what this means, and how necessary it will probably be found for other provincial newspaper proprietors to follow suit; but even the outside public will be able to understand in a large measure the importance of the innovation.

The Brussels Hotel-de-Ville.—The work in connection with the electric lighting of this edifice is assuming an increased importance. M. Léon Gérard, who carried out the initial installation, has recently been entrusted with the lighting of the hall in which the meetings of the Communal Council take place. This hall, which is of great historical interest, is one of the grandest in the whole building; it is magnificently decorated in the Louis XV. style, and the ceiling is painted by Janssens. To the great moulded cornice of the ceiling are attached 100 16 candle-power lamps, which bring into brilliant relief the gilding with which every projecting point is ornamented. An extremely soft and rich effect is produced by this lighting of the ceiling. The meeting hall of the sections is illuminated by 72 16 c.p. lamps, carried by three bronze lustres. The lighting of the hall intended for the operations of the militia is effected by two Pilsen arc lamps, each taking 12 amperes. The installation at present comprises 700 incandescence and two arc lamps. The original motive power having become insufficient, it is proposed to connect the Hotel de Ville mains with those belonging to the installation carried out by the same firm at the Laeken Gasworks, and employed for lighting the stage at the *Théâtre de la Monnaie*.

Barcelona Exhibition, 1888.—The Secretary of State for Foreign Affairs has communicated to the Society of Arts a despatch from Her Majesty's Ambassador at Madrid, reporting on the present state of the intended Exhibition at Barcelona, in which Sir Francis Clare-Ford refers to the condition of the Exhibition, and the rapid progress which is being made in the improvement of the City of Barcelona by the erection around the Exhibition of many fine buildings. Gardens are being laid out where before were unseemly pieces of waste ground. An aquarium is to be built on the sands, and commodious bathing houses and tents are to be erected, one of these is to be arranged for the special use of the Queen Regent. It is stated that there will be over 30,000 exhibitors, of whom only 80 are English. 3,500 square yards are assigned to the Barcelona Province alone, of which 3,000 have already been secured. The first batch of goods for the exhibition has arrived from Germany and Austria; and great efforts are being made to insure the success of the French portion of the exhibition. In the agricultural pavilion a space of 800 square yards has been assigned for French agricultural products. The ambassador expresses the opinion that the date for the opening of the exhibition will have to be postponed, as it cannot be ready much before the first week in May.

The Brussels Tramways. From the following passages in the report of the Directors, read at their meeting on the 15th inst., it would appear that electric traction has not yet given results as satisfactory as those which were expected:—"Yielding to the wishes expressed, or rather, to the requests formally put forward, by an influential section of the shareholders at the general meeting of March 15, 1886, we have made some trials of electric traction. Up to the present the experiments have not fulfilled the expectations of those who promoted them. The working by

electricity was commenced on April 17 by a car travelling between Rue Belliard and the Place Royale. A second car was appropriated to this service on May 8, and a third on September 19. These three cars are at present working at the line de la Loi. In 1887 the electric cars travelled over 54,987 kilometres and replaced 4,800 'horse-days.' We shall endeavour to obtain better results, especially from the point of view of the economic maintenance of the apparatus. Until we have succeeded in so doing, we do not propose to increase the number of electric cars which are at present running.' The above meagre and insufficient statement as to kilometres and "horse-days" must be supplemented by other information, and more particularly by details as to cost of working, before the determination arrived at by the Directors can be rendered intelligible.

Dust on Electric Light Leads.—Mr. G. A. Nellis, writing to *The Electrical World*, says:—"We have in our Allegheny County Station here in Pittsburgh a line of 'direct' (continuous current) and a line of 'alternating' wires side by side, both supplying lights of the same candle power and voltage. Both lines were put up at the same time, the lights started together, and they burn the same at all times. The alternating current wires are as clean as when we put them up; but the direct wires are as dirty as they could well be. There is no trouble whatever to distinguish the one from the other; there is such a contrast. Mr. Nellis also points out that the ceiling is blackened on both sides of the lead fastened to it, and that the accumulation of dust is more noticeable on the positive than on the negative wires. The facts, as stated, are of some interest, and we shall be glad to receive any details of further observations in relation to them. The theory advanced to explain them does not, however, appear to us a *vera causa*. It is that 'magnetic whirls' are induced around the wire when a current of electricity is sent through it, and that the magnetism acts on the atmosphere, attracting the paramagnetic oxygen and repelling the diamagnetic nitrogen, and thus, in some manner, which is not explained, attracting some of the particles of dust and repelling others. We think that the phenomenon is much more probably due simply to electrostatic charge.

The Electric Light in France.—In our issue of the 2nd inst. the establishment of a central station for lighting the town of Grenade sur Garonne was mentioned. This installation would appear to be an admirable example of what can be done in a rough and ready way by local enterprise. *L'Electreux* observes in relation to it that it would be difficult to carry out such work in a more simple, rustic and economical manner. The motive power is supplied by a turbine erected on the river Save. This works a four-pole dynamo on the Parent and Kierulff system, double wound, and giving a constant potential at a speed of 900 revolutions per minute. The public lighting comprises 90 street lamps and 16 electric candles, which are worked at the contract price of 4,000fr. per annum. The lamps supplied to subscribers are also worked under contract at the marvellously low price of 5 centimes per day per lamp of 10 c.p. and 10 centimes per day per lamp of 16 c.p.; the renewal of the lamps being, of course, at the expense of the subscribers.—At Perpignan, a company for the distribution of the electric light has just been established. It has already obtained the necessary authority for carrying the leads through the streets, and is carrying on negotiations with the municipality in relation to the public lighting. The existing gas company regards this competition as a

very serious matter.—The municipality of Havre invites tenders for the establishment of a central distributing station in that city.

Royal Meteorological Society.—The exhibition which is ordinarily held during the present month by this Society was this year of a very interesting character, being devoted to apparatus relating to the study of atmospheric electricity, which has been on view at the Institute of Civil Engineers during the three days ending on the 23rd inst. An extensive collection of electrometers and various forms of lightning conductors and protectors were shown. The collection of articles damaged by lightning attracted much attention, including as it did the clothing which was torn from the body of a man during the storm of June 8th, 1878. He was imprudently standing under a tree at the time of the occurrence. The lightning flash, after ripping his smock frock from end to end, severed his leathern gaiters, tore the trousers into shreds, and finally split up each boot from ankle to toe. The man, we are informed, was not killed, but it is perhaps unnecessary to add that he has since entertained a very wholesome dread of thunderstorms. Various examples of the effects of lightning on trees are also to be seen, with pieces of wood and bark actually severed in storms of recent years. There is also a set of objects designed to upset the very popular idea as to the falling of thunderbolts. In one case it is shown that the alleged thunderbolt was in reality an old cannon-ball, while in another instance it is asserted that the dread visitant which had created so much alarm was nothing more than a piece of coal. The photographs of lightning flashes are both numerous and excellent, and the exhibits in this class should certainly be inspected by painters, whose representations of the appearance of the discharge are invariably of a conventional character.

The Electric Light at Southampton.—The garbage and town refuse of Southampton is largely disposed of in a "destructor." This means the generation of heat, which is turned to account in raising steam; and of this circumstance advantage was recently taken by the borough surveyor (Mr. W. B. G. Bennett) to carry out an interesting experiment in electric lighting. The dynamo used for the production of the electric light in connection with the Jubilee illuminations being still in Southampton, the borough surveyor obtained permission for its temporary use. The process by which the results are attained is as follows:—The town refuse provides the destructor with fuel to feed the furnaces; the heat generates steam in the boilers; the steam pressure propels the engine, and the engine drives the dynamo which produces the electric current. So that the power by which the lighting is obtained practically costs nothing for fuel. The current is supplied direct from the dynamo, and all the lights are under perfect control by the use of a separate switch for each light. At present the circuit supplies 12 glow lamps and four arc lights, each of the latter being equal to 3,000 candle-power. The maximum capacity of the dynamo will furnish light for 10 of the 3,000-candle arc lights, or 30 of 1,000 candle-power, or 250 glow lamps. By the present arrangement one central arc light illuminates the whole of the Corporation Wharf of three acres, while light is provided for the office, the wheelwrights' shop, the engine-house, and the destructor. Beyond the outlay for the dynamo and the necessary arrangements, there is said to be practically no expense for the production of the electric light, except that involved in

supervision and attendance. The cost is stated to be considerably less than that of the present gas lighting.

Milan (Porte Simplon) Terminus. Some interesting information in relation to the lighting of this important railway terminus and shunting station has been recently published by M. Cosmann, engineer to the *Chemin de fer du Nord*. The terminus was in the first place lighted by petroleum; but the result obtained was insufficient, especially during the fogs prevalent in Lombardy. A plan of lighting by means of improved gas burners was abandoned by reason of the expense. A first trial of electric lighting which was made in 1884 having given favourable results, it was definitively decided to adopt this system, which has been in successful operation for the last three years. The illumination of the line junctions is obtained by means of three arc lights mounted on iron masts, whilst the shunting is carried out by means of three lights supplied with lenses. Two of the three masts are 12½ metres high, and carry lights equivalent to 990 candle burners, and each consuming 33 amperes and 50 volts. The third mast, 9 metres high, carries a lamp of 528 carrels, taking 20 amperes and 50 volts. The three arc lamps for the projected light are each of 990 carrels; the lenses with which they are supplied being of the Balestrini system. The motive power is supplied by two steam engines each of 35 h. p., one of these only being generally in use. The dynamos, six in number, are continuous-current machines of the Siemens type. The expenses of working the installation, from July 7, 1885, to June 30, 1886, are summed up as follows:—

	Francs.
Motive Power	14,910
Staff	12,140
Carbons for lamps	5,813
Beltting, &c.	3,674
Gas lighting of engine shed	870
	37,467
Total expense of establishment	141,944fr.
Representing in interest and sinking fund at 5 per cent.	11,194
Or for 6 lights during 3,824 hours, and a total lighting power of 5,178 carrels	51,661
The expense is therefore 2.59fr. per lamp hour, or 0.00025fr. per carrel hour. The advantage of being able to carry out the work within the station with the same security during the night as during the day is one that is fully appreciated.	

American Tramway Notes. The Observatory Hill Road, with electric traction, is now in successful operation. The cars, with fifty passengers, climb an up-grade of nearly 1 in 10 at six miles an hour, and attain a speed of fifteen miles an hour on the level. The Woonsocket Street Railway Company, who made an eight weeks trial of a Thomson-Houston motor last year, have expressed themselves satisfied with the results attained; and it is expected that they will equip their cars with about ten motors in the spring. A trial of the Julien Brush electric car was recently made in St. Louis. The car was in active operation for five hours, and during that time it made twelve trips over the Washington avenue line. Various speeds were tried, and the grades were experimented on, with satisfactory results. Most of the patrons of the line took advantage of the experiments, and got on the car, which was thus filled compactly at every trip. As Mr. Baumhoff expressed it, "A bushel of nickels was taken in." The car shed is on Twenty-second-street and Washington avenue, and the charging current, which is supplied by the Brush electric light

works, is transmitted to the shed by wire from Seventh and Walnut streets. The test is said to have given satisfaction, and others have since been made with similar results. The Julien Company complain of the poor quality of the steel driving chains made in America compared with those made in England. They are now importing their chains, but are striving to obtain others of equal quality in the home market. For some months the Sprague Electric Railway and Power Company have been quietly experimenting with a new storage battery of their own design, and they believe that they have arrived at results much more satisfactory than any hitherto attained. The details of the battery are not yet made public, but we understand that President Whitney, of the West End Street Railway Company, Boston, has decided not to introduce the cable system, nor make any other change in the motive-power in use by that Company, until the Sprague Company has completed its experiments upon it, and shown whether it is a good thing or not. Mr. Thomas, professor of physics of the Ohio State University, has been conducting a series of experimental tests of the Short overhead system of electric railways in operation at Columbus, Ohio, and is said to be surprised at the degree of efficiency obtained.

Overhead Wires. A conference of the delegates appointed by various metropolitan vestries and district boards of works was held Thursday, March 15, at the Lambeth Vestry Hall, Kennington (Mr. F. H. Fowler in the chair), when delegates were present from the following vestries and district boards:—Vestries: Bethnal Green; St. Giles's, Camberwell; Clerkenwell; Kensington; Lambeth; St. Martin's-in-the-Fields; Newington; St. George's, Southwark; St. Leonard's, Shoreditch; and St. James's, Westminster. District Boards: Greenwich, Hackney, St. Saviour's and Wandsworth. The following resolutions were unanimously carried: 1. That, in the opinion of this meeting of delegates from the various metropolitan vestries and district boards of works, it is desirable, in the interest of the inhabitants of the metropolis, that, as a general principle, all telephone, telegraph, and electric lighting wires within the metropolitan area should be placed underground. 2. That the control of the construction and maintenance of all telephone, telegraph, and electric lighting wires in the parishes mentioned in Schedules A and B to the Metropolis Local Management Act, 1855, should, whether within 15ft. of the surface of the road or not, vest in and be under the direction of the vestry or district board of the parish or district in which such telephone and telegraph wires are situated. 3. That in order to prevent any separate vestry or district board refusing, arbitrarily the passage of through wires across their parish, to the detriment of other parishes, an appeal should be allowed to the Metropolitan Board of Works similar to that sanctioned by Section 211 of the Metropolis Local Management Act, with reference to the orders or acts of the vestry or board in relation to buildings, sewers, &c. 4. That, considering the serious invasion, not only of the public, but also of private rights proposed by the Bill of the United Telephone Company, the various vestries and district boards be recommended to adopt the foregoing resolutions, and to oppose the Bill, with the view to have the principles embodied in such resolutions incorporated in the Bill, and such other amendments as are detailed in the petition of the Metropolitan Board of Works against the Bill. 5. That copies of the foregoing resolutions be sent to all the vestries and

district boards of the metropolis and to the Metropolitan Board of Works. 6. That each vestry and district board be asked to petition Parliament against the Bill, and to oppose it through the local members of Parliament.

Alkalies and the E.M.F. of Zinc.—In a recent paper, M. J. H. Koosen discusses the property of alkalies increasing the E.M.F. of zinc. For the following extract from this paper we are indebted to the Chemical Society's *Journal*:—Grove, Joule, Poggendorff, and others have observed the increased E.M.F. obtained by substituting aqueous potash or soda for the dilute acid in a cell. The author states that, according to his researches, the alkali, say, potassium hydroxide, has a fourfold action: (1) it breaks up into potassium and oxygen; (2) potassium replaces zinc in its electrical action—for instance, in a Daniell's cell potassium sulphate is formed in place of zinc sulphate, as the copper is deposited; (3) the zinc is oxidised by the oxygen of the potash; (4) the resulting zinc oxide is dissolved by the aqueous potash. (1) Diminishes the E.M.F., whilst (2) and (3) increase it; (4) may possibly slightly increase it, but it would be desirable to have positive evidence on this point. If the external resistance of a cell is very great, almost the whole heat of combination will be developed in the external circuit. Let the E.M.F. of a Daniell's cell be taken as the unit of E.M.F., and let the unit of heat be the amount generated in a Daniell's cell by the decomposition of n grams of zinc, where n is the atomic weight of that metal. Then from Thomsen's determinations, the E.M.F. of a Daniell's cell is given by the equation $\text{ZnSO}_4(248) - \text{CuSO}_4(198) = 50 = 1$ Daniell; and with potash substituted for dilute sulphuric acid $\text{K}_2\text{SO}_4(337) + 2\text{ZnOH}_2\text{O}(166) - 2\text{KHO}232 - \text{CuSO}_4(198) = 73 = 1.46$ Daniell. For the author's zinc-bromide platinum cell, $\text{ZnBr}_2(91) = 1.82$ Daniell. The result thus theoretically obtained in the case of these and a few other simple cells considered by the author agree closely with experimental determinations. The heat of combustion of zinc oxide and potassium is not taken into account, as it is certainly not more than 2 per cent. of that due to the decomposition of zinc in a Daniell's cell, and according to Favre and Silbermann it would seem that this chemical action is merely local, and does not contribute to the electrical energy. Practically, the author finds that a Daniell's cell with a solution of potassium hydroxide is very satisfactory for giving continuous currents through a high resistance, and sodium hydroxide gives still better results, as sodium sulphate, being more soluble, does not so readily crystallise on the porous cell. It is very important to prevent interdiffusion of the fluids as far as possible, and for this purpose the author uses a double porous cell, having the intermediate space filled with a solution of potassium and sodium sulphates respectively, with a small admixture of sulphuric acid to diminish the resistance. Cells of this kind have been kept joined up through a resistance of 20 or 30 ohms for weeks together without any perceptible diminution in the E.M.F. The alkaline solution must not be too dilute, or the zinc will soon become coated with oxide. The author states that his zinc-bromine-platinum cell is still better for giving a continuous current through a high resistance. It requires no porous cell, has a high E.M.F., and has been kept in continuous action for months without any change in the E.M.F.—in fact, until one or other of the elements was completely decomposed. The only precaution necessary is to cover the bromine with a layer of petroleum, which completely prevents all evaporation and smell.

THE ELECTROLYSIS OF COPPER SULPHATE IN STANDARDISING ELECTRICAL INSTRUMENTS.*

BY A. W. MEIKLE (THOMSON EXPERIMENTAL SCHOLAR).

Owing to the great increase in the use of electricity in recent years, and the consequent importance of having accurate measuring instruments, it is necessary that electricians should have some accurate means whereby they may have their standard instruments readily and cheaply checked from time to time. Much might be said for a national recognition of this fact by the establishment of a system of electrical standards, just as we now have national standards of length, weight, &c., but such a subject is beyond the province of this paper, in which I propose to give a description of the electrolysis of copper sulphate, which has been employed for standardising purposes in the Physical Laboratory of Glasgow University for the last two years with the most satisfactory results.

FIG. 1.

A paper communicated by Mr. Thomas Gray to the *Philosophical Magazine* for November, 1886, dealt with the question of the reliability of copper electrolysis as compared with silver. The conclusion drawn from the investigation described in that paper was, that while silver in the hands of a trained experimenter left nothing to be desired in point of accuracy, still it is open to the objection that it is very costly where large currents are used, and requires great care in making the experiments. Copper, on the other hand, has the advantage of simplicity in manipulation, and where attention is given to a few necessary precautions great accuracy can be obtained. As an example of the difficulties in the use of silver I may mention that the deposit which is always crystalline in form, requires careful handling in order to prevent loss in drying or weighing, and in order to get it thoroughly adherent to the plate the area of the cathode or gain plate should never be less than 200 or more than 400 sq. cms. per ampere. With copper the deposit for areas exceeding 20 sq. cms. per ampere is thoroughly adherent to the plate, of which,

FIG. 2.

indeed, it forms an integral part. Thus in making an electrolysis of copper sulphate for 100 amperes, a current density of 1 ampere to 50 sq. cms. would give excellent results, and the total area of gain plates would only be 5,000 sq. cms., while were silver used the area would require to be from 20,000 to 30,000 sq. cms. One disadvantage which copper has is its readiness to oxidise when exposed to the air, more especially when being taken out of the sulphate of copper solution, but if the mode of cleaning and drying the plates, both before and after electrolytic action, which is described in this paper, be employed, this difficulty is easily overcome. I have kept plates for a week after being treated in this manner without being able to observe any change of weight as indicated by a chemical balance, which is sensitive to 1/10000 of a gramme.

* Paper read before the Physical Society of Glasgow University, January 27th.

Another point, which has to be taken into account, is the fact that the plates lose weight in the solution at a rate varying with the area they expose to the action of the acid which is contained in all electrolytic solutions of sulphate of copper capable of giving reliable results. This question was gone into very fully by Mr. Gray about two years ago, and the results are given in his paper on electrolysis which is referred to above. It has again been gone into when making some experiments on the effect of temperature on the loss of weight of the plates in the solution. The results of these experiments, which were made by passing the current through ten cells in series,

FIG. 3.

each of which had a different area of plate, is to confirm the experiments made by Mr. Gray, and to show that the amount of variation from the true electro-chemical equivalent of copper due to differences of current density can be allowed for with great accuracy. Before describing particularly the results of these experiments, it may be well to refer briefly to the apparatus used.

Electrolytic Cells. The electrolytic cell found most convenient for small currents consists of a round glass jar nearly filled with sulphate of copper solution, into which three vertical plates with their surfaces parallel and about 15mm. apart are held by means of rigid platinoïd clips. The two outside clips are joined together and the plates held in them are the anodes or loss plates (*see* Fig. 1). Two loss plates are always put into each cell, one on each side of the gain plate, so that the gain plate may receive a

FIG. 4.

FIG. 5.

uniform deposit on each side. The centre clip which is well insulated from the two others holds the cathode or gain plate. The clips for holding the gain plates are formed of straight pieces of No. 6 platinoïd wire about six inches long, a portion of which, about four inches long, is filed flat, and on to this another piece of platinoïd, bent so as to form a powerful spring is soldered at *a*, so that the two ends of the pieces form a firm contact at *b* (Fig. 1). A binding screw for fixing on the electrode is screwed on to the other end at *c*. Several of the clips so formed are firmly clamped on to a rectangular wooden frame by screwing a strip of wood down on the top of them, the portion of the clip between the wood being well insulated by being covered by a piece of thick indiarubber tube.

The clips for holding the loss plates are formed in the same manner as the gain plates, but are made in pairs by bending a piece of No. 6 platinoïd wire into the shape of a U, with about three centimetres between its ends, and then

soldering on the springs as already described. These clips are insulated and fixed on to the frame on the opposite side from the single clips, so that the end of the latter comes just between the two ends of the former as shown in Fig. 2. A flexible covered copper wire, of convenient length to enable the cells to be joined in series if desired, is permanently soldered on to the bend of the double clips. This mode of placing several sets of clips on a wooden stand is found very convenient, as the plates can readily be adjusted in their position, or taken out without disturbing any of the other arrangements. This form of clip suits very well for currents up to about 15 amperes, by joining the cells in series or parallel as may be necessary. In using electrolysis for small currents up to 2 amperes, it is advisable to use two or even three cells in series, as with small deposits a check is thus obtained on the weighings or any defect in an individual cell. With currents from 3 to 15 amperes, I prefer still to use this form of clip, and a sufficient number of cells in parallel, each having gain plates of about 130 sq. cms. in area, so that the plates, owing to their comparative lightness, may be weighed on the chemical balance—the additional number of weighings being more than compensated for by the additional accuracy obtained.

For currents, such as are used in standardising a deca or hecto ampere balance, owing to the large amount of copper deposited, such delicate weighing is not necessary, and a balance sensitive to about 2 milligrammes may be used; but even were an error of 5 milligrammes made in weighing the plates of an electrolysis for 50 amperes

water as it comes from the Glasgow Corporation's water pipes until a density of from 1.15 to 1.18 is obtained, and then adding one per cent. of free sulphuric acid. In all the experiments mentioned in this paper the solution used has been of a uniform density of 1.175, but it has been found that a variation in density from 1.1 to 2 makes no difference in the nature or quantity of the deposit. With solutions made up as described perfectly accordant results have invariably been obtained. The solution should not be used too often, as the acid is after a time exhausted by action with the plates, and it has been found from experience that unless the solution is decidedly acid the plates are oxidized in the solution and very irregular results are obtained, which are quite valueless for accurate standardising. The table of curves (No. I.) shows very clearly the difference between results obtained from solutions which have free acid, and those which have not.

The five curves are taken from experiments made with ten cells in series and different areas of gain plate in each. The abscissæ are areas of gain plates in square centimetres

continued for one hour, the error would only amount to about $\frac{1}{100}$ per cent. For high currents, such as these, a large earthenware cell is used, which is shown in Figs. 3 and 4. A wooden frame is fitted on to the top of this cell, and on two opposite sides of this frame and well insulated from each other, two copper bars are screwed, one having 10 and the other 11 spring contact clips of the form shown in Fig. 5. The plates for this cell are made of sheets of copper each of which has a rigid strip of copper soldered to its top edge and projecting about two inches on each side of the plate. On putting the plates into the cell one end of this strip fits into a clip and the other rests in a vulcanite notch on the other side of the cell. Each of the plates when in position exposes a surface of 1,100 sq. cms. to electrolytic action, so by putting in the proper number of plates the cell can be used for currents up to 200 amperes. The plates and clips are so arranged that one gain plate comes between two loss plates, and the latter always exceed the former in number by one. As the plates, when all are put in, are very close together two cross tubes bent so as to form U's, and long enough to reach to the bottom of the cell, are hung over each loss plate to prevent any danger of the plates touching. Two flexible electrodes suitable for dipping into mercury cups are attached to the bars carrying the clips.

The Solution for the Electrolytic Cells.—The solution used is made by dissolving commercial copper sulphate in pure

per ampere, and the ordinates are deposits in grammes. It will at once be observed that the curves I., II., and III. are exactly similar in form. Curve I. is the mean of about twelve experiments made with free acid in the solution. Curves II. and III. are from two single experiments also with about 1 per cent. of free acid in the solution. Curve IV. is taken from an experiment made with solution which had been used too often, and the results are irregular, owing to oxidation of the plates in the solution. Curve V. shows the results obtained from a solution in which some copper oxide had been dissolved so as to withdraw all the free acid. The gain plates were found to be very much oxidised when taken out of the solution, and had a dark brown colour instead of the bright metallic surface which they have when taken from a solution which contains acid.

Preparation of Plates. The gain plates used are made from ordinary high conductivity sheet copper about $\frac{1}{16}$ of a millimetre in thickness. For the smaller cells they are cut in the shape shown in Fig. 6, as this form of plate, owing to the flexible tongue, is very easy to adjust in its position, and when in use the whole plate is immersed in the solution except the narrow tongue necessary to hold the plate between the contact clips, thus leaving a very small area exposed to any possible oxidation by the atmosphere. This form of plate has also the advantage that the area exposed to electrolytic action can be got at once, or may be permanently stamped upon the tongue, and the proper equivalent for the current

density can be taken without having to measure the area covered by the deposit. The edges of the plate are all smoothed, and the corners rounded off, as the deposit is apt to form on any rough edges, especially if a high current density is being used, or if the current is being run for a long time. When this has taken place the plates, owing to the roughness of the surface, are not so readily dried, and the risk of oxidation is increased, as is also the risk of losing part of the deposit should the plate accidentally strike against any object. The surface of the plates is burnished with fine glass paper until perfectly bright and smooth, then rubbed with a piece of clean cloth, and finally wiped gently with a piece of silk to remove any shreds, after which they are ready for weighing. Another plan, which has been successfully employed, is to polish the plate with silver sand and water, to which a few drops of sulphuric acid was sometimes added. The plates are then washed in clean water to remove the sand, and placed in a vessel containing pure water with a little sulphuric acid in it to remove any oxide which may have formed during the washing. From this they are taken one at a time, quickly dipped in fresh water, and dried immediately on clean white blotting paper, then held before a fire to remove any trace of moisture which might remain. The method which has been found most convenient, however, is to place a

sheet of No. 1 glass paper on a wooden roller and spin it in a turning lathe, holding the plate against it by a pad. When the plates have been burnished by this method, the sand paper, which is only held on the roller by two springs, is removed, and a piece of rough cloth put on instead. On this cloth the plates receive a final polish to remove grains of sand, then wiped with a piece of silk as in the first method, after which they are ready for weighing. Care should be taken never to touch with the fingers the portion of the plate intended for immersion in the cell, as by so doing the surface is spoiled for a deposit, and the mark of the finger is seen distinctly after the electrolytic action.

Loss plates are also made from high conductivity copper, but from a thicker sheet so that they may last for some time. No great trouble need be taken with them, except to see that they are not put into the liquid when badly oxidised, in which case the free acid in the solution unites with the oxide on the plate, and the solution suffers in consequence, as I have already explained. For this reason, too, the loss plates should never be left in the solution when not in use, but should be taken out and placed in water with a few drops of H_2SO_4 added, or, if they are not likely to be required again for some time, they should be dried and put away.

Size of Plates.—Loss plates should never have an area of less than 40 sq. cms. per ampere. If the area is much less than that, the resistance of the cell becomes high and

variable owing to the formation of copper oxide on the plate, and if it be made very small, gas is given off at its surface, making it impossible to keep the current steady, and giving a result of no value for accurate standardising. The gain plates should never expose a surface of less than 20 sq. cms. per ampere. When too high a current density is used, the deposit is not so adherent to the plate, and a portion may be lost in washing and drying. It is always best to use an area of from 50 to 100 sq. cms. per ampere, using the larger area for currents which are intended to run for some time. By doing so any little roughness round the edges is avoided, and in consequence the plates are easier to dry.

As already mentioned at the beginning of the paper, the amount of copper deposited by a given current varies with the area of the plate exposed to the corrosive influence of the free acid in the solution of copper sulphate. This variation is not the same as it would be were no current running, in reality it is less, from which it would seem that the current exercised some protecting power. This subject has been very fully investigated in the Physical Laboratory, as also the effect of temperature on the rate of loss, and the results of the experiments are shown in the table of curves No. II., and the two tables of numbers which I shall speak of presently.

The experiments were made with ten cells in series, all carefully insulated from each other, and each cell having a different area of gain plate, the extreme range being from about 30 to 500 sq. cms. per ampere. The solution used in all cases was 1.17 in density with 1 per cent. of H_2SO_4 added. From former experiments described in Mr Gray's paper on electrolysis before mentioned, no difference could be observed in the amount or appearance of deposits from solutions containing percentages of acid varying from

FIG. 7

1 per cent. to 5 per cent. at a temperature of about 12deg. C., but owing to the very rapid consumption of the free acid in the solution at the higher temperatures, fresh solution was used each time.

The curves show the results obtained for different areas of cathode or gain plate, and each curve is for a different temperature between 2deg. C. and 35deg. C. It will be observed that they all converge rapidly towards the point of crossing, which shows that the same deposit would be had at all temperatures were it only possible to use a small enough area of gain plate. The curves were produced to cross the line of ordinates, and the point of crossing was taken as 10,000 and the other points reduced to correspond so as render percentage corrections easy for different current densities. The ordinates are therefore numbers proportional to the weight of copper deposited in grammes, while the abscissae are areas of gain plate in square centimetres per ampere.

The curve for 2deg. C. is the mean of three experiments, which were in very close agreement. It is rather curious that for a range of current density almost up to 130 sq. cms. per ampere, there is no effect made by variations in the area of gain plates, but the same tendency is shown in the curves for 12deg. C., 23deg. C., and 28deg. C., although to a much smaller extent. The curve for 12deg. C. is the mean of a large number of experiments which were in very good agreement among themselves. It is the average curve which is shown as the mean curve in the first table, but on a different scale. The effect of temperature from 16deg. to 18deg. C., which is about the ordinary range of temperature in the Physical Laboratory of Glasgow University, is very small and may be neglected. Indeed, with a gain plate of 50 sq. cms. per ampere, the total variation in the corrected equivalents for 12deg. and 28deg. C. is only about $\frac{1}{10}$ per cent. The curves for 23deg. C. and

C. are two single experiments, while the curve for C. is the mean of two experiments, which were in agreement with each other. A glance at the curves show how important the question of temperature is at the high points. In countries where 28deg. 6deg. C. were normal temperatures a very careful care would require to be made for any variation. No. 1 gives the numbers from which the second of curves is taken, and table No. 2 gives the corrected chemical equivalents as calculated from these numbers for current densities from 1 ampere to 50 sq. cms. 1 ampere to 300 sq. cms.

Standardising Arrangements.—The arrangements for standardising consist, as shown in the diagrams, in joining in a constant battery, the instrument to be standardised, electrolytic cells, and a variable resistance. Care should be taken to join the instrument directly on to the electrolytic cells, and have that portion of the circuit well led so as to be sure that the instrument is recording the exact amount of current which is going through the

simplest form of arrangement is shown in Fig. 7, suitable for currents up to 10 amperes. The variable

FIG. 8.

once used in this case is one of Sir William Thomson's. For currents up to 1 ampere a high resistance of platinum wire is used, and for currents above that a large rheostat of stranded copper wire—the potential of the battery being first adjusted to suit the case. With large currents beyond the carrying of any rheostat a conductivity bridge is put in circuit for the purpose of varying the current. This bridge consists of a number of platinum U's of sufficient length to heat much with any current which the potential

of the battery can send through them. By dipping the two ends of these U's in two parallel mercury troughs, any desired conductivity can be put into the circuit. Fig. 8 shows two of the large bridges, one of which is standing in the mercury troughs, while the other is standing on the insulated sides. The large bridges are kept apart by wooden distance pieces, as shown in the figure, while the small ones are supported on strips of wood through their whole length, and are fitted with thick copper terminal pieces. The copper rheostat before mentioned is joined in parallel to this bridge, and the whole arrangement, as shown in Fig. 9, simply takes the place of the rheostat in the former arrangement. We have found this last arrangement very useful for standardising instruments, as, with the battery power at our disposal, any current up to 500 amperes can be had by continuous steps. The apparatus being arranged as stated above, trial plates of the same area as the gain plates to be used are put into the electrolytic cell, and the current is adjusted to the required reading on the instrument. The circuit is then broken, the trial plates are replaced by the cleaned and weighed gain plates, and current is again made—the exact second being noted on an accurate timekeeper. The instrument should be found very nearly to record the desired reading, and should at once be adjusted by turning the rheostat, and by that means be kept steady during the experiment. Any error arising from the current not being at the proper strength on starting is very small. As a rule the current,

FIG. 9.

when previously adjusted as above, is, practically speaking, exactly correct when made for the standardising, but should it chance to be even so much as 5 per cent. wrong, an amount which with the precautions taken is entirely out of the question, it can easily be set right in at most 10 seconds, with apparatus such as has been described, and the whole error on an experiment lasting for one hour would only be about $\frac{1}{100}$ per cent. The current should be run until the amount of the deposit will be such that any possible error in weighing or in starting or stopping the current is, practically speaking, eliminated. In breaking the current the exact second is again noted, and the plates quickly removed from the clips, and placed in a glass vessel containing pure water with a few drops of H_2SO_4 added to prevent oxidation. From this they are taken one at a time, dipped in pure water, then dried and weighed, as before described in the process of cleaning with silver sand. The jaws of the clip are always opened before putting in or taking out the plates, so that there will be no error due to loss of weight by the friction of the plate with the spring contacts. The zero of the instrument is always carefully noted before and after the experiment.

STANDARDISINGS OF SIR WILLIAM THOMSON'S STANDARD CURRENT BALANCES.

As showing the degree of accuracy which can be obtained by the electrolysis of copper sulphate, I shall briefly give the results obtained from the standardisings of Sir William Thomson's standard current balances, the constants for which have been determined by the methods I have described. There are in the Physical Laboratory at the present time seven of these balances, whose measuring range is as follows:—

1. Hecto-ampere Balance, range from 20 to 500 amps.
2. Deci " " " " 4 to 100 "
3. Ampere " " " " 1 to 25 "
4. Deci-Ampere Balance (a) range from 2 to 50 deci-amperes.
5. " " (b) " " 1 " 25 "
6. Centi-Ampere Balance (a) " " 2 " 50 centi-amperes.
7. " " (b) " " 1 " 25 "

(1) The constant of the Hecto was first found by electrolysis, and they were calculated from the result of the experiments. On being again checked by electrolysis on December 2nd, 1886, with its adjusted weights instead of 100 amperes as indicated by the instrument, the mean of two experiments gave a current value of 99.996 amperes.

(2) The Deca ampere balance was standardised by direct comparison with the Hecto, and on being checked by electrolysis on February 15th, 1887, a result of 49.978 amperes was obtained against a current of 50 amperes read on the instrument. The latest comparison still shows the instrument to be in perfect agreement with the Hecto. It has also been twice standardised by electrolysis at intervals of 5 months which gave results respectively of $\frac{1}{25}$ per cent. and $\frac{1}{50}$ per cent. too low.

(3) The constant of the ampere balance was determined by electrolysis, and on afterwards being compared with the Deca it showed a variation from that instrument of $\frac{1}{80}$ per cent.

(4) The constant of deci-ampere balance (a) was twice determined by electrolysis, which gave a difference of $\frac{1}{800}$ per cent. between the two standardisings. Its weights were taken by calculation from the result of these experiments, and on being again checked by electrolysis the result showed $\frac{1}{50}$ per cent. too large on a current of 4 amperes as read on the balance.

(5) Deci-ampere balance (b) was standardised by direct comparison with centi-ampere balance (c), and on being afterwards compared with deci-ampere balance (a) showed a variation from that instrument of less than $\frac{1}{800}$ per cent.

(6) The weights for centi-ampere balance (a) were determined by direct comparison with an old and now disused form of deci-ampere meter in June, 1887. Since that date it has been checked at intervals by four separate electrolysis experiments, which gave results respectively of $\frac{1}{10}$ per cent., $\frac{1}{10}$ per cent., $\frac{1}{10}$ per cent., and $\frac{1}{10}$ per cent. too large, which is very satisfactory when the small weight of the deposit is considered. Compared with deci-ampere balance (b) this instrument is in absolute agreement.

(7) The constant of centi-ampere balance (b) was determined by direct comparison with centi-ampere balance (a), from which, though comparisons have been made from time to time for the last six months, no variation whatever can be observed.

We have thus a chain of instruments measuring from one centi-ampere to 500 amperes, which are, practically speaking, in absolute agreement among themselves, and whose constants have been determined separately, and in many cases by different observers, by the process of electrolysis of copper sulphate described in this paper. This fact not only proves the constancy and accuracy of the instruments, but also establishes beyond a doubt the great value of the method of standardising, and that it is equally applicable to currents of all magnitudes.

ON THE COST OF CENTRAL STATION LIGHTING.

BY R. E. CROMPTON.

[The following article, referred to by Mr. Crompton in our correspondence column last week, is taken from our excellent contemporary, *Industries*.]

An article under the above heading appeared in *Industries*, page 598, Vol. III., and it professed to deal with the comparative costs of distributing electricity by the three kinds of transformers now available, viz.: (1) accumulators used as transformers; (2) what Sir William Thomson calls "step down" dynamos used as transformers; (3) the well known alternating transformer system as used on the Grosvenor Gallery installation, and also by Westinghouse and others. In that article a great deal was said as to the great advantages, in point of cheapness, of the system I have placed third in order; and I will now proceed to show how the conclusions arrived at in that article may be considerably modified in favour of the accumulator transformer system, if the latter be treated in a somewhat different manner to that proposed by the writer of the article. I think he put this system in a false position by going too far in the direction of reducing current and increasing the E.M.F. No one will

doubt that in a large number, in fact in the majority of cases, the generating station can be placed at a distance not exceeding one mile from the nearest part of the district requiring electricity for lighting or motive power purposes, and I propose to show that in these cases, when battery transformers—or what I shall briefly call the B.T. system—is used, the cost of the plant will only slightly, if at all, exceed that for an equivalent supply from alternating transformers which, for convenience, I shall call the A.T. system. I prefer not to compare what might be done, but what has been actually and successfully done in the way of transforming by batteries with what has been done by alternating transformers.

At Vienna, the system proposed by M. Monnier, and successfully carried out by myself, consists of charging from a central station groups of batteries of accumulators, charged continuously in series. From each group four circuits are led off, so as to cut down the E.M.F. from 400 volts to 100 volts, to suit the lamps used. This system has now been in use continuously for six months, and there has been no hitch or trouble whatever in working the plant. It is almost needless here to remark that the troubles connected with the boilers about which so much has been written, have had nothing whatever to do with the electrical plant. No difficulty has been experienced in charging continuously at the high pressure necessary, and although no special precautions were taken with the inside wiring of the opera, and other places supplied, no danger or difficulty has arisen from the use of this high pressure. We may therefore consider it proved that a system of supply which uses a charging current at a potential sufficient to fully charge four batteries arranged in series each at 100 volts, and which supplies at times of average maximum demand for electricity, two-thirds of the current direct from the dynamos without any loss whatever, and one-third only from the accumulators, can be worked successfully and economically, and with a far greater margin of security against temporary stoppages of the light than could possibly be the case with either alternating or direct current transformers without storage.

It remains now to compare the cost of the B.T. system when applied to an installation of the dimensions proposed in the article, with the figures given as the cost of the installation by alternating current transformers. Taking the items in the order previously given, I shall consider first the cost of motive and dynamo power. As I have said, the dynamos supply two-thirds of the maximum net output of 600 kilo-watts, and as in this case there will be no loss of current, but only of E.M.F., in the regulating appliances, which may be safely taken at 12 per cent., we require 448 kilo-watts at the terminals of the batteries, or, adding the 10 per cent. loss in the mains, 500 kilo-watts in the generating station. If I add to this the 20 per cent. of extra motive and dynamo power the writer of the previous article proposes to allow as reserve, we must provide for 600 kilo-watts, equal to 1,000 i.h.p. Such a plant may conveniently consist of six sets of combined engines and dynamos, each of 100 kilo-watts, or 166 i.h.p.

£12 per i.h.p., the sum allowed in the former article, appears to me an excessive estimate for engines and boilers only, and, as it tells equally on both sides of the comparison, I propose to reduce it in both cases to £8 12s. per i.h.p., for which sum, I believe, more than one contractor of repute could be found ready to supply and fix the boilers, steam and exhaust pipes, feed apparatus, triple expansion engines, ready to be coupled on to the dynamos. I adopt the figures given as the cost of the dynamos, and from the two I work out the cost of the motive power to £8,700, and the dynamo power £4,800. For the A.T. system I adopt the figures formerly given—viz., 1,150 i.h.p., which at £8 12s. comes to £12,500, and for the dynamos and exciters £5,540. For purposes of comparison, a sum ought to be added representing the cost of site and buildings in both cases; and, as stated in the article, the cost of this would be nearly in proportion to the space occupied by the machinery. I propose to add on this account £8,000 to the B.T. system and £11,000 to the A.T. system. Next as to cost of charging mains. As I read the article, these mains in the case of the B.T. system will extend only from the generating station to

the accumulator stations in the district. If we take the length of this main at one mile exterior to the district, and 240 yards inside it, or 2,000 yards in all, the total length of circuit being 4,000 yards, the current 1,200 amperes, and a loss allowed of 10 per cent. or 40 volts, its resistance must be 0.04 ohm. A double conductor, having a collective area of about 2.55 square inches, weighing about 45 tons, and costing at £80 a ton, £3,650, will be sufficient. This can be laid, supported on earthenware or porcelain insulators, in a brickwork-in-cement culvert, for £1,500 or, say, £5,150 in all. In the case of the A.T. system, the mains, for purposes of comparison, must be laid under ground, and as in this case the charging mains are practically co-extensive with the charging as well as the distributing mains of the B.T. system, it will be convenient to consider the cost of the street work as common to both. The cost of the cheapest and most trustworthy method of laying distributing mains under flag footways, and under ordinary street crossings, varies in London from 14s. a yard of double main, if the section is as small as would be laid for carrying 40 amperes, to 16s. per yard, if conductors having $\frac{1}{4}$ square inch of section of copper are used.

Before proceeding further, it is necessary to consider what length of house frontage will be probably required for a supply of 10,000 60 watt lamps burning simultaneously. I believe recent experience in London and elsewhere has shown that the ampere at 100 volts, i.e., 100 watts per yard of useful frontage of houses supplied, is a good figure to use. For the 6,000 ampere or 600 kilo-watts we supply 6,000 yards of useful frontage, and this on the supposition that every house takes the light. But it is not unreasonable to say that for years to come 20 per cent. in excess of this frontage must be supplied with mains, or 9,000 yards actually facing the houses, to which we must add at least 35 per cent. for crossings and other portions of the road traversed by the mains, which do not face what I call useful frontage. This makes 12,000 yards in all. From the figures I have before given, these 12,000 yards of distributing mains for the B.T. system, at $\frac{1}{2}$ in. section of conductor, would cost £9,600; and those for the A.T., at the smallest useful section, would cost £8,400. To the latter figure must be added an item of £2,400 as the cost of one mile of main outside the area of supply. Before leaving the subject of the distributing mains it will be convenient here to consider the question of the cost of the house connections. When underground conductors are used it is necessary to provide one surface box with connections for every two houses. Now, as the whole of these must be put down in the first instance at the time the mains are laid, we must estimate for their supply for both systems. In London the house fronts vary from 24ft. to 60ft., and taking the rather high average of 40ft., or 10 yards, we would require a surface box for every 30 yards, or 450 boxes for the 9,000 yards of useful frontage. Pricing these at £2 for each surface box fixed, we must add £900 to both estimates.

The battery transformers have to supply 200 kilo-watts per hour during the hours of maximum supply. A great deal hangs on this most important question of the duration of the hours of maximum supply; but in London it is found not to extend beyond three hours per day in winter. If we supply four batteries of accumulators which will have a total capacity of 1,000 kilo-watts, we shall provide for five hours of extreme demand, which is a condition of things extremely unlikely to occur, even in times of fog. We require thus four batteries, each having a capacity of 250 kilo-watts, and capable of being discharged at fair efficiency, at a rate of not less than 650 kilo-watts. Such accumulators can be obtained, either in England or on the Continent, from at least three different makers, and can be fixed and set to work for the sum of £8,640. In one of these cases the makers guarantee that, to meet a breakdown of the charging plant or of the charging mains, a demand at the rate of 250 kilo-watts can be supplied by each battery without injuring it in any way, but of course for a comparatively limited period. This would provide against any panic or annoyance to the users of the light caused by a temporary stoppage of the charging current, even if it occurred at the period of maximum demand. In all such

cases as this which I am now estimating, when ample allowance has been made for spare machinery, and when the charging mains can be laid and insulated in two parallel sections, such stoppages are unlikely to extend beyond a few minutes, so that in this point the B.T. system offers enormous advantages over its rivals.

The cost of the alternating transformers appears to have been largely under estimated in the former articles. The writer there stated that a maximum supply of 10,000 lamps would be obtained from such a small number as 150 transformers. Most people will admit that such distribution is extremely unlikely to occur in London, whatever might be the case in New York or some of the Continental towns. When I was above considering the distributing mains I showed that 9,000 yards of mains fronting the houses would be required in order to obtain 10,000 lamps lighted simultaneously, and I suppose that these mains would front 900 houses, of which only 600 would take the light. It follows that, if every consumer has his own transformer fixed, 600 must be provided, and at the lowest estimate this could not be done, including the fixing of them, at a loss charge than £20 per house, or £12,000 for the whole. Even if we suppose that one transformer could be provided for every two houses, we cannot estimate the total cost at less than £7,500, and in order to avoid possible criticism on this ground, I propose to enter this lower figure in my comparative statement; but it will be very interesting to hear the opinion of the advocates of the A.T. system on this point, as it very vitally affects its first cost. The statement I have thus arrived at shows that the cost of 10,000 60 watt lamps supplied simultaneously will be approximately the same, viz., £49,000 for both systems, a result which differs very widely from the figures given in the previous article. I leave the figures to speak for themselves, and shall have more to say on the matter after I have heard a few of the criticisms which I may reasonably expect from those who believe in the A.T. system.

COST OF GENERATING AND DISTRIBUTING PLANT FOR 10,000 60-WATT GLOW LAMPS, BURNING SIMULTANEOUSLY.

With Secondary Batteries.

Motive power, six 166 i. h. p. watts = 996 i. h. p., at £8 12s.	£8,700	0	0
Dynamoes	4,800	0	0
Building to suit above	8,000	0	0
Charging main, 45 tons at £80	3,650	0	0
Laying ditto in culvert	1,500	0	0
Distributing mains, 12,000 yards at 16s. per yard	9,600	0	0
Service boxes, 450 at £2	900	0	0
Batteries, four sets of 50 cells each	8,640	0	0
Regulating gear	1,000	0	0
	£48,790	0	0

With Alternate Current Transformers.

1,450 i. h. p., at £8 12s. per i. h. p.	£12,500	0	0
Dynamoes and exciters	5,540	0	0
Building to suit above	11,000	0	0
Charging main	2,400	0	0
Distributing main, 12,000 yards at 14s. per yard	8,400	0	0
Service boxes, 450 at £2	900	0	0
Regulating gear	500	0	0
Transformers, assuming one large one for two houses, 300 at £25 (including fixing)	7,500	0	0
	£48,740	0	0

Effect of Light on the Electric Discharge.—It has been conclusively established by the researches of Prof. H. Hertz that the extreme ultra violet rays of the spectrum have a certain influence on the passage of the electrical spark, by which the potential at which discharge takes place is sensibly diminished. These researches have been supplemented by those of E. Wiedemann and H. Ebert, who have found that the effect is not limited to the ultra violet rays, but extends to the more refrangible visible rays of the spectrum. They point out also the curious circumstance that the effect takes place only when negative electricity passes through the spark region. In the case of positive electricity, no difference was noticed when the spark region was illuminated. In the Geissler tube the discharge of negative electricity, which was intermittent when no light fell on the spark, became continuous when the spark region was subjected to the action of the violet or ultra violet rays.

THE ELECTRICAL ENGINEER.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. *Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places.	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., who was in his scientific prime at the beginning of the century. This will be followed by SIR HUMPHREY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

FIRE OFFICE RULES.

The electric lighting industry is subject to two kinds of adverse influences, those arising from within and those arising from without, of which the former are the worst. Insurance is universal. Electrical engineers know that the buildings they light have to be insured, and it is in their interest that the work done should be of such a character as to conform to the rules of the insurance office. The latter has to pay the piper, and must, of necessity, call the tune. Compliance therewith is a matter of detail. An electrical contractor, in his communication to our columns last week, directed attention to the fact that a new set of rules had been issued which would have the result of introducing confusion everywhere. We have to deal with actual facts, and, in face of these, would make certain suggestions. It is a fact—and, if there be any who doubt the statement, they may, by a little investigation, prove the assertion for themselves—that, so far, the only rules followed in practice have been those of the Phoenix Fire Office. These have grown with the growth of the industry, and were the outcome of the united experiences of the engineer of the company and the best electric light contractors. They have been found to work fairly well, and, all important from the insurance point of view, have, when followed, proved effective in preventing fires. This, too, should add to their value from the electrical engineer's point of view. It surely is not in his interest to have a disastrous fire traced to his work. Our readers must bear with us if we say hard things. We have to look at the future as well as the present. The firm getting an order for an installation is no doubt pleased in the extreme. The work is done; the money received, and the profit added to the bank balance. If, however, the installation does not prove a success, and should, unfortunately, be the cause of a fire, that work does harm to the industry out of all proportion to the money value of the work done. Our cry then should be "rather too strict than not strict enough." If the Phoenix rules were calculated to unduly put forward that office there might be some reason for having other sets; but surely any office can accept a risk under the rules. The multiplication of rules will add immensely to the difficulties of electric light engineers, and especially so in the question of tendering. It may be said that the consulting electrician will specify under what set of rules the contractor has to tender, and it is implied that the consulting electrician will use those rules which meet with his approval. That is impossible unless all meet with his approval; for in most leases it is distinctly stated the insurance must be in such and such an office. The solicitor settles which office before the tenant comes in, and long before the consulting electrician comes to the front. It may be argued that the electrician will

tical conclusions of the lecturer. In the first place the material of which the rods are composed may, on the whole, be better of galvanised iron than of copper. To protect high chimneys, a sheet of metal on the top, connected to a number of points similar to those of barbed wire fencing, and in contact downwards, by ordinary galvanised telegraph wires, to bands of metal around the chimney, the wires ultimately making in duplicate as good "earth" as can be obtained, constitutes probably the best solution of the problem. The protection of ordinary houses should be by barbed wires along ridges and eaves connected to the water pipes, but not to the gas pipes, nor to projecting iron balconies, and taken to good "earth" by ordinary galvanised telegraph wires. If the whole roof can be of metal so much the better. It is a mistake to think that an ordinary lightning conductor protects a given area; it does nothing of the kind, and the theorising of the French writers in this direction, pricked as it was by Mr. Preece some years ago, must now be taken to be completely exploded. We have been among those who heretofore insisted upon periodical testing, but our views are somewhat modified upon this point; not, however, as to the testing, but more as to the manner of testing. Prof. Lodge suggested a method of testing which no doubt will receive careful attention from practical men; but it will be best to leave discussion upon this part of the subject for a future opportunity. Meanwhile there can be little doubt as to the correctness of the general conclusions advanced. They accord with experimental evidence.

CORRESPONDENCE.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

Sir: However great the difference of opinion existing between electric light contractors and fire office inspectors, the advent of two more sets of rules in addition to those of the Phoenix Fire Insurance Office will not tend to simplify matters.

It is to everyone's interest to reduce electric lighting to its simplest form, an object which will certainly not be forwarded by having various authorities all looking at the subject from their own point of view.

The stage to which matters has come has more especially been brought under my notice by my having been asked to draw up a set of rules for one of the larger fire insurance offices. The effect upon the public mind will hardly be reassuring when they have to choose between conflicting opinions, every one of which is said by its upholder to be the one and only way of carrying out electric light installations.

Whilst one does not wish an approach to the "go-as-you-please" license given to gas engineers, one does not wish to fall into the opposite extreme of having to take unnecessary precautions.

I had hoped that the days of firms who put in second class materials and scamp their work were coming to an end, but the time for this seems to be likely to be still further prolonged if there are several standards of work.

Unless the Society of Electrical Engineers or the Dynamicals will take the matter up in a broad spirit, it would be as well to have a meeting of those interested, and for them to appoint a committee consisting of representa-

tives of the fire offices, the electrical societies, consulting engineers, and electric lighting firms, &c., to draw up a set of rules. The present Phoenix Fire Office Rules might be taken as a basis, and altered or added to, so as to include any points considered advisable by the committee.

Finally, let this one set of rules be acknowledged, as probably it would be by the fire offices, electrical societies, and the profession generally, as the standard by which work must be carried out.

It might be an advantage to have a committee of appeal for new and disputed points in installation work, and there also might be a definite list of risks made out for different classes of buildings, such as theatres, private houses, mills, &c., together with the class and description of insulation that would be passed for such risks—this probably varying with different systems of lighting and the rate at which the building is insured.—Yours, &c., F. L. RAWSON.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

Sir: "Electrical Contractor," in his letter of the 16th inst., puts the question of fresh insurance rules in a very forcible manner.

I do not think that there is the least doubt that if only electrical contractors, as a body, had been consulted, they would have given an unanimous verdict against the issuing of fresh rules, or interfering with those that have so long held the field. These new rules are solely attributable to the unsuccessful attempt, on the part of the Society of Telegraph Engineers, to obtain for themselves the credit of having originated the only recognised insurance rules in existence. If there is a *clique* who seem to have tardily discovered the fact that they have had no hand in the issuing of these rules, and have some objections to them, why do they not come forward and state those objections?

If they did this I feel confident that the Phoenix Company would be only too glad to entertain any reasonable suggestions they might make in order to render their rules as perfect as possible. This issuing of fresh rules will create the utmost trouble and confusion, especially amongst good and first-rate firms, who will be cut out altogether by those who will take advantage of a multiplicity of rules to put up cheap and bad work, besides unnecessarily alarming the public, who will immediately take it for granted that if electricians cannot mutually agree how to put up installations there must be very considerable danger run in adopting the electric light.

In future, how are specifications to be drawn up for installations? Which set of rules will be taken as a basis of the way in which the work is to be executed? Supposing a building is fitted with the electric light, and insured in several offices, each having its own set of rules, how will it be possible for the contractor to get his work passed by the various insurance inspectors if each is going upon his own lines? Hitherto, where a case has arisen as above, it has nearly always been sufficient to inform the other insurance offices that the installation had been put up in accordance with the Phoenix Fire Office Rules, and passed by Mr. Heaphy. Now all this will be changed, and contractors will have a sorry time of it. Consulting electricians will also be powerless to better the situation, as they cannot hope to get rival promoters of rules to agree to any but their own.

This question is of such momentous importance to all electrical firms that unless a combined movement be made, and that at once, to counteract this action, a blow will be struck at our industry from which we shall suffer long and severely.

As it seems to be a question that only concerns electrical contractors, and not telegraph engineers, professors, or other learned scientists, the former should at once take steps to bring forward their united opinions, and, in so doing, I hope there will be many who will share the views of

ANOTHER ELECTRICAL CONTRACTOR.

March 20th, 1888.

ALTERNATE CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

Sir: I notice in your late issues a series of reports of the discussion on the above subject at the Society of Telegraph-

very difficult mechanical problem to convey the same amount of energy by a wire rope as in the cable system. The weight of the cable has to be moved, and it must be supported by sheaves placed along the line at short intervals, while a large tunnel must be built to contain it. The sheaves all consume power, and have to be constantly oiled and watched, and by their constant recurrence prevent any thorough cleansing of the conduit. Elaborate and complicated construction is necessary for curves and switches, while the connecting and disconnecting of a heavily-loaded car to and from a swiftly moving cable is a difficult and wearing process. The best cable engineers estimate that more than 75 per cent. of the engine power is consumed in moving the dead weight of the cable, and this rarely lasts over a year, or a year and a half. When electricity is used, on the other hand, the conduit contains only the stationary and permanent copper rods, and no mechanism is employed to wear and give trouble. Connection with the car is maintained by a light sliding contact bearing gently against the conductors, and the conduit excavation need be only large enough to permit of drainage between catch bits. So far, then, as the transmission of power is concerned, the simplicity and convenience of the electrical method is unrivalled.

Its efficiency is equally satisfactory. The dynamo-electric machine, by which the power of the steam-engine is converted into electricity, has reached a degree of perfection unappreciated by those not engaged in the business. Less than five years ago the best dynamos gave an efficiency of 75 per cent.; there was an excessive heating of the wire coils and of the journals, so that a machine could rarely be depended upon for a run of twelve to eighteen hours at a stretch. There were frequent burnings out of the armature and of the commutator, and other recurring faults, which caused uncertainty and expense. At present the best manufacturers sell their machines, both dynamos and motors, with a guaranteed efficiency of 90 per cent., so that for every 100 h. p. of the steam-engine 90 will appear on the line in electricity, and 81 will appear in the motor in the form of mechanical energy. The latest series of tests made with railway motors demonstrated an efficiency of 80 per cent. from the steam-engine to the car axle. From this must be deducted, in actual practice, 5 per cent. for the line wire, and 10 per cent. for contingencies of all kinds, leaving 65 per cent. actually to be relied on. Therefore, from 100 h. p. at the engine, 65 will be delivered on the car axle.

The capacity of machines has increased in like ratio. A machine that would formerly operate 35 or 40 arc lamps has been worked up to operate 65. At the same time the reliability of machines has been improved. Their electrical and mechanical construction has been brought to such a degree of perfection that little more can be desired. And while the electrical machines have been worked up to this point, special engines for driving them have been developed, and special appliances devised for protecting both dynamos and engines from all possible accidents and interruptions. This growth has been unostentatious, but rapid and sure; and at present the transmission of energy by electricity is thoroughly and completely practicable, thousands of horsepower being every day obtained from electric motors. The application of the motor to railway use has been steadily developed during the last four years. Various difficulties have been met and overcome. The conduit system, involving greater difficulties and expense than the overhead system, has gone somewhat slower, but both are now in shape for practical everyday use. The peculiar adaptability of the electric motor to railway use is not fully appreciated except by those intimately acquainted with it. It will be described in this article as plainly as possible in the space that is available.

The work of propelling a tramcar is characterised by wide variations in the amount of power required, and by wide variations in the character of it. The power is measured by the product of the tractive pull into the velocity, and there is found to be a variation in the total product required, and also a variation in each of the factors entering into it. A motor for street-car work must be capable of wide variation in tractive force to correspond with the variations in grade on the line. The quite ordinary grade of 5 per cent.,

for instance, may require about eight times the traction that is necessary on a level. For this reason motors that have but little range of pressure must fail; for while on a level the pressure will be ample for the load and will accelerate the speed so as to do a large amount of work, it will not give sufficient traction for a grade or curve. In an electric motor, on the other hand, the pull increases as the square of the current, and is limited only by the magnetic saturation of the iron cores. This limit is so remote that it is best appreciated by the fact that in practice a motor capable of moving 15 tons up a grade of 8 per cent. weighs, with gearing, but 1,600 lb. By admitting three times the current to the motor that is necessary on a level, the traction can be increased nine times.

It is another peculiar feature that the necessary increase of current automatically takes place by reason of the tendency of the electric motor to slow up under an increased load. This slowing tendency and the acceleration due to the resulting increase of current, meet each other at a point always dependent on the load at any given time. This follows from the following considerations: A dynamo and motor are the same machine working in converse ways, the dynamo converting mechanical into electrical energy, and the motor converting back electrical into mechanical energy. When acting as a dynamo the machine has also a motor action, due to its own current, which opposes the driving engine, and in overcoming which the power of the engine is consumed. When acting as a motor, on the other hand, it has also a dynamo action, tending to set up an electromotive force against the direct or actuating electromotive force. The efficiency of the transmission depends on the ratio between the direct and counter electromotive forces, and, as the resistance of the motor is constant, the current through it will depend on the excess of the one over the other. Any slowing of the speed, therefore, causes a large current to pass through the motor, and this produces a much greater traction, since the traction increases as the square of the current. There are other elements which come in to modify this result somewhat, but which we need not enter into. As a fact in practice, the traction automatically increases in a much greater ratio than the speed decreases, corresponding very closely with the variations in traction and speed that the service on most short railways demands. For the large majority of cases, therefore, the electric motor is nearly self-regulating, an artificial resistance being used for stopping, and occasionally for going very slowly and restraining too high a speed.

The great capacity and compactness of the electric motor are evident qualifications for railway work.

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting on Tuesday, the 13th of March, the President, Mr. Bruce, being in the chair, the paper read was on "Economy Trials of a Non-Condensing Steam Engine—Simple, Compound, and Triple," by Mr. P. W. Willans, M.I.C.E.

The author described a series of economy trials, non-condensing, made with one of his "central valve" triple-expansion engines, with one crank, having three cylinders in line. By removing one or both of the upper pistons the engine could be easily changed into a compound or into a simple engine at pleasure. Distinct groups of trials were thus carried out under conditions very favourable to a satisfactory comparison of results. No jackets were used, and no addition had, therefore, to be made to the figures given for feed-water consumption on that account. Most of the trials were conducted by the author, but check-trials were made by Mr. MacFarlane Gray, Professor Kennedy, Mr. Druitt Halpin, Professor Unwin, and Mr. Wilson Hartnell. The work theoretically due from a given quantity of steam at given pressure, exhausting into the atmosphere, was first considered. By a formula deduced from the ϕ & ψ diagram of Mr. MacFarlane Gray, which agreed in results with the less simple formulas of Rankine and Clausius, the lbs. weight of steam of various pressures required theoretically per indicated h. p. hour were ascertained (see table). A description was then given of the main series of trials, all at 400 revolutions per minute, of the appliances

Intended mean admission-pressure	lb.	40	90	110	130	150	160	170

used, and of the means taken to ensure accuracy. A few of the results were embodied in the table. The missing quantity of feed-water at cut-off, which, in the simple trials, rose from 11.7 per cent. of 40lb. absolute pressure to nearly 30 per cent. at 110lb., and at 90lb. was 24.8 per cent., was at 90lb. only 5 per cent. in the compound trials. In the latter, at 160lb., it increased to 17 per cent.; but on repeating the trial with triple-expansion it fell to 5.46 per cent., or to 4.43 per cent. in another trial not included in the table.

On the other hand, from the greater loss in passages, &c., the compound engine must always give a smaller diagram, considered with reference to the steam present at cut-off, than a simple engine, and a triple a smaller diagram than a compound engine. Nevertheless, even at 80lb. absolute pressure the compound engine had considerable advantage, not only from lessened initial condensation, but from smaller loss from clearances, and from reducing both the amount of leakage and the loss resulting from it. These gains became more apparent with increasing wear. The greater service in a compound engine had not the injurious effect sometimes attributed to it, and the author showed how much less the theoretical diagram was reduced, by the two small areas taken out of it, in a compound engine than by the single large area abstracted in a simple engine. The trials completely confirmed the view that the compound engine owed its superiority to reduced range of temperature. At the unavoidably restricted pressures of the triple trials, the losses due to the new set of passages, &c., almost neutralized the saving in initial condensation, but with increased pressure, say to 200lb. absolute, there would evidently be considerable economy. The figures of these trials showed that the loss of pressure due to passages was far greater with high than with low pressure steam, and that pipes and passages should be proportioned with reference to the weight of steam passing and not for a particular velocity merely. The author described a series of calorimetric tests upon a large scale (usually with over two tons of water), the results of which were stated to be very consistent. After comparing the rates of initial condensation in cases where the density of steam, the area of exposed surface, and the range of temperature, were all variables, with other cases (1) where the density was constant, and (2) where the surface was constant, the author concluded that, at 400 revolutions per minute, the amount of initial condensation depended chiefly on the range of temperature in the cylinder, and not upon the density of the steam, or upon the extent of surface, and that its cause was probably the alternate heating and cooling of a small body of water retained in the cylinder. The effect of water, intentionally introduced into the air-cushion cylinder, corroborated the author's views, and he showed how small a quantity of water retained in the cylinder would account for the effects observed. At lower speeds surface might have more influence. The favourable economical effect of high rotative speed, *per se*, was very apparent. In a trial with a compound engine, with 130lb. absolute pressure, the missing quantity, at cut off rose from 11.7 per cent. at 405 revolutions to 29.56 per cent. at 130 revolutions, the consumption of feed-water increasing from

20.35lb. to 23.67lb. This saving of 14 per cent. was due solely to increase of speed. Similar trials had been made with a simple engine. In one simple trial at slow speed the missing quantity rose to 44.5 per cent. of the whole feed-water. The author compared a series of compound trials, at different powers, with 130lb. absolute pressure, and various ratios of expansion, with a series giving approximately the same powers at a constant ratio of expansion, but with varying pressures, being practically a trial of automatic expansion against throttling. Starting with 40 indicated h. p., 130lb. absolute pressure, four expansions, and a consumption of 20.75lb. of water, the plan of varying the expansion, as compared with throttling, showed a gain of about 7 per cent. at 30 indicated h. p., but of a very small percentage when below half-power. If the engine had an ordinary slide-valve, the greater friction, added to irregular motion, would probably neutralize the saving, while if the engine were one in which initial condensation assumed more usual proportions, the gain would be probably on the side of variable pressure. Even as it was, the diagrams showed that the missing quantity became enormously large as the expansion increased. Judging only by the feed-water accounted for by the indicator, the automatic engine appeared greatly the more economical; but actual measurement of the feed water disproved this. The position of the automatic engine was, however, relatively more favourable when simple than when compound. In conclusion, the author referred to a trial with a condensing engine, at 170lb. absolute pressure, in which the feed-water used was 15.1lb., a result evidently capable of further improvement, and to an efficiency trial of a combined central valve engine and Siemens dynamo, made for the Admiralty, at various powers. At the highest power the ratio of external electrical h. p. to indicated h. p. in the engine was 82.3 per cent. Taking the thermo-dynamic efficiency of the engine at 80 per cent., that of the combined apparatus would be nearly 66 per cent.

Electric Motors. Mr. F. L. Pope, in an article which appears in *Scribner's Magazine*, draws attention to the ignorance which prevails in the popular mind in reference to the true position of the electric motor. Thus he shows that the idea of employing this motor to propel vessels across the Atlantic, for instance, is altogether a fallacy. He points out that electricity in its application to machinery is not in itself a source of power, but is merely a convenient and easily manageable derived form of energy. At the best, he says, the electric motor is only a secondary motor, which must derive its power from some primary motor, such as a steam engine or turbine. This latter statement would not apply, however, if the electric motor were worked in connection with a thermo-electric generator. But, unfortunately, we can at the present moment see no prospect of the thermo-electric battery becoming an economical means of converting heat into electrical energy. Until some such means be perfected, the field practically occupied by the electric motor must be that of supplying a convenient means for distributing the power economically evolved on a large scale by prime motors worked by steam, water or, perhaps, wind.

INDEPENDENT ENGINES IN INDEPENDENT STATIONS.*

BY WILLIAM LEE CHURCH.

(Concluded from page 249.)

The typical daily chart of amperes delivered from an incandescent station of, say, 4,500 lights, is shown in Fig. 2, of course with variations in different stations, but always of the same general character. The chart is assumed to cover a winter night's run, commencing at 4 p.m., and shutting down at 8 a.m. The heavy, irregular line A B represents the fluctuation of the actual load, such as would be determined by indicating a series of independent engines; and the area enclosed between it in the base line M N may be denominated by the net power required. The line, irregular line C D encloses the gross load when driven by a single large engine, being equivalent to the net load plus the friction of the shafting and pulleys required in transmission. The irregular band lying between A B and C D, therefore, represents the dead load, which would be a dead loss, due to the friction of the shafting. But, as shown above, this is the full measure of the loss. We have already seen in, Fig. 1, that an excessive underload requires a relative amount of steam which would be adequate to produce a much greater power if applied in an engine worked at its point of maximum efficiency. Combining the two diagrams, therefore, we would find a third dotted line, E F, which would clearly represent the actual steam consumption required to secure the network A B. The irregular band, therefore, between A B and E F, represents the total loss expressed in coal; in other words, the entire area E F M N represents the lamps which should be got for the steam expended, whereas

FIG. 1.

Fig. 1 illustrates the paragraph on Corliss engine. *a b* indicates cut off. *c d* rate of consumption if economy unaffected by the load. If diagram represents actual performance it shows engine is at its best only from *a* to *c*.

A B M N represents the lamps actually got for the steam expended. The loss involved is practically 50 per cent. of the total fuel in the whole night's run, which corresponds to observed results in stations whose fluctuations of load are about as indicated. Of course there are stations in which the net load averages more uniform than that shown, and a better proportionate result would therefore be expected from the single large engine with countershafting. We believe it is safe to say, however, that there is no incandescent station which will get a load so constant as to secure the economy from a single engine equal to that which can be realised from subdivided power.

We now contrast the performance of independent engines in the same station. The lower narrow band between the lines M N and *a a* represents the smallest dynamo, equal to a load of 650 lights. The remaining three bands between *a a*, *b b*, and *c c* represent the other dynamos, or successive loads of 1,300 lights each. At starting time, therefore, a 60 h.p. engine with its 650 light dynamo is started, and run continuously until shutting down in the morning. It will be noted that, while running, the load on this engine is practically constant and at the point of maximum efficiency. In ten minutes after starting, the load rapidly increasing, it becomes necessary to start the second 125 h.p. engine with its 1,300 light

dynamo, which engine again runs on its full and most efficient load, as indicated between the lines *a a*, *b b*. This engine is stopped at 12 45, and is therefore running to a disadvantage only for the last hour. At 4:40 the increase of light calls for the third engine with its dynamo, which in turn runs until 10 45, and is then stopped. The fourth engine and dynamo will start at 3 p.m., and run until 9 30. The point to be clearly understood as vital to the whole economic question is that each engine while running is loaded to its best efficiency, runs only so long as its load is called for, then stops altogether, and with it all consumption of steam, leakage, radiation, wear and tear, and loss of every nature. Ample time is given to inspect the engine and dynamo if necessary, and the system as a whole develops the last possibilities of commercial efficiency.

The above diagram practically represents the performance of two stations which we once had the privilege of comparing. Both were practically the same size, and both were constructed on the same electrical basis. We were by courtesy put in possession of the monthly reports from both of these stations, which showed a ratio between the pounds of coal per ampere per hour of 70 to 126 in favour of the station driven by independent engines. A station whose motive power is one or two large engines, therefore, finds itself in a position of earning money between starting time and 10 o'clock, and spending it again between 10 o'clock and morning.

We have thus endeavoured to make it clear in the above illustrations that the rated economy of the two types of engines is but a small part of the consideration, and cuts practically no figure whatever in actual practice under the conditions imposed by the nature of incandescent service.

FIG. 2.

If any one is now thinking to inquire, why not use a number of small Corliss engines in place of high speed engines, if it is admitted that the Corliss type is more economical of the two? we would answer briefly, first, small Corliss engines are not as economical as small single-valve engines, the percentage of leakage due to the four valves and slower speed being much greater; second, small engines of the Corliss type run necessarily at so slow a speed as to preclude the possibility of direct belting, and to involve full lines of counter-shafting with their attendant cost and waste of power; third, the first cost of small slow-speed engines is very greatly in excess of that of high speed engines of the same power. We think no one has ever seriously considered, however, the adoption of small independent slow speed engines.

Next in importance to reliability and economy is uniformity, delicacy, and continuity of regulation.

There is much misapprehension regarding the matter of regulation in engines used for electric lighting. Let us, therefore, ask, What is good regulation? Good regulation implies, as a matter of course, reasonably small variation of speed, reckoned in R.P.M., between the engine fully loaded and the engine running light. Claims are made that such and such engines regulate to 2 per cent., 1 per cent., and even to one-half of one per cent., under variations of load. Now, it should be clearly understood, once for all, that any decent automatic engine controlled by the shaft governor can be so adjusted as to not merely to 2 per cent., or 1 per cent., but to actually pass the point of exact regulation, and run faster under load than when light. So far

* Paper read before the National Electric Light Association.

as regulation in terms of R.P.M. is concerned 1 per cent. or 2 per cent. regulation is sufficiently close for all ordinary purposes.

Second. The most important consideration in the regulation of engines in incandescent stations is not their variation from minute to minute, but from stroke to stroke. An engine may make 300 turns per minute, counted for each successive minute of the hour, and yet may at any given instant be running sensibly above or below this speed, in the effort to meet a momentary fluctuation of load. We say every engine may do this, and we have observed that most engines do this frequently; the difficulty being, not a matter of the construction of the governor, but purely a question of lubrication. A perfect governor is one which will maintain the speed, not at an average of 300 R.P.M., but at the rate of 300 R.P.M. for each and every stroke. Any properly constructed governor will retain the average of regulation to which it is set, but it can only secure instantaneous regulation when friction is practically eliminated. It has been our experience that nothing but a complete bathing of the governor in oil will practically accomplish this purpose, and maintain its perfection throughout a long run.

Incandescent lamps require a regulation more delicate, perhaps, than any other industry. Any departure in regulation from stroke to stroke gives a variation of electromotive force, which is speedily destructive to the life of the lamp—the item which, next to fuel economy, is the heaviest taxation. The injury is done during the period of acceleration immediately following the change of load, which period is the time between the change of load and the movement of the governor; and this in turn is proportional to the friction. It is obvious that, if friction were annihilated, the acceleration would be also *nil*, and the speed, and consequently the electromotive force, would never vary.

Third. Under the extremely long runs now imposed by electric lighting service continuity of good regulation is essential; that is to say, a governor which will regulate when well oiled will fail to regulate when its pins and bearings, being inaccessible under motion, have become dry during a long run.

As to the nicety of regulation obtainable from a slow-speed engine, there is no comparison possible. We have already shown that it is not permissible for an electric light engine to vary its speed, even from stroke to stroke. A slow-speed engine not only may do this, but actually does vary its speed within the limits of a single stroke. All observers know that it is frequently quite possible to count the revolutions of a slow-speed engine, particularly when heavily loaded, by the pulsations in the lamps at a distance from the station. A slow-speed engine, unless excessive in its fly-wheel capacity, will imperceptibly slacken in passing its centres; and this variation, not visible on the engine, becomes a sensible and dangerous variation when multiplied to the speed of the dynamo. The fluctuation of the needle of two voltmeters, respectively registering from a high-speed and slow-speed engine will give abundant evidence on this point.

Flexibility.—The characteristic of flexibility in electric light stations is one which is frequently overlooked until experience demonstrates its desirability. To secure the best possibilities in this direction it is necessary to use dynamos of two or three different sizes—say of 650, 1,300, and 2,600 lights capacity—each being driven direct from an independent. The plant being thus divided into independent units of different sizes in any variation of demand, either in the total load or in the load required for different centres, can be conveniently met. Owing to local causes, the load of a station is not necessarily the same from day to day. It is obvious that a plant in which all the dynamos are hung upon one, or at most two, engines, is essentially rigid in its control of circumstances, whereas a station planned as above indicated, is to the last degree flexible in meeting any variation of load, to whatever degree it may occur. All this has a direct bearing, both on economy of life and incidentals of operation.

We would wish to imply that the smallest unit in every station should necessarily be the smallest dynamo—say 650 lights. It is probable that the smallest unit is determined by the minimum load existing at any considerable

time during the day. This minimum load in the majority of medium-sized stations will represent about one-eighth to one-sixth the generating capacity of the station; that is to say, a station of 4,000 lights capacity should have one dynamo at least as small as 650 lights. Beyond this, it is perhaps advisable that the units be uniform for the sake of interchangeability of parts. The whole question of units of generation must be considered, not in the light of any one rule, but under all the circumstances of each particular case.

Maintenance of Plant.—The maintenance account of a plant often defeats dividends in the use of counter-shafting, bearings, pulleys, clutch pulleys, belts, &c. No practical operator need be told of the repair account and general annoyance from the use of clutch pulleys. There are incidental exceptions, but we refer to the general rule. Each bearing of the counter-shafting will consume oil to the value of at least five dollars per annum, and any considerable amount of shafting involves the pay of an extra oiler to properly care for it. Regarding the two types of engines under discussion, it is undoubtedly true that the maintenance of the high-speed engine will be fully as low as of an equal horse power in slow speeds, as to its actual expense, without taking into account the time lost in repairs. Nearly all high-speed engines are made to gauge with more or less reference to interchangeability of parts. Repairs, in consequence, are furnished at a minimum of cost; and, the parts being light and readily handled, the engine can be stripped and overhauled and connected up without the employment of an extra force of men or the necessity of heavy handling. In referring to high-speed engines, we of course only speak of those which are carefully and understandingly designed for the work put upon them—that is, we wish to draw a sharp distinction between high-speed engines and engines speeded high.

Space Occupied.—This is one of the minor considerations which in certain locations becomes of considerable importance. Not infrequently electric light stations are located near the business portion of a city, where real estate is valuable, and taxes correspondingly high, and space counts heavily in the capitalized investment.

Again, a large building obviously increases the investment, particularly when we know that a building to carry heavy lines of shafting at high speeds must be of unusually massive construction. It needs no illustration to show that independent engines, by doing away with the space occupied by counter-shafting and belts under the least distance between centres which can be justified, require materially less space per horse power than any form of non-subdivided power. This is particularly the case where the dynamos are placed on the second floor, over the engine room.

Moreover, the cramped space in which the single engine must develop and distribute its power is against its satisfactory performance. The fact is generally overlooked in drawing comparisons that a single large engine in an ordinary manufacturing establishment, such as a cotton mill, has in the nature of the case a wide space in which to transmit its power from the slow motions of the engine up to the high speed of the spindles. This means that ample space is given to bring the speed, by gradual accelerations, through easy moving shafting of substantial nature, up to a moderately high intermediate speed, and then distribute it to the spindles in small quantities, by means of simple and light fast running devices. In the dynamo room, on the contrary, the space is cramped to the last degree, and the slow running engine must, in short range, multiply its power to high velocities, and transmit its speed in large units to the dynamos. The whole system of transmission becomes rigid and ineffective, and the loss consequent upon friction and risk to *employment*, and the magnitude of disaster when any occurs, are such as in themselves to overbalance all the economy which the most enthusiastic advocates of slow-speed engines attribute to them.

Extension of Plant.—An electric light station, unlike most other industries, is usually, of very rapid and persistent growth, to an extent which is not generally foreseen in the original calculation. The use of independent engines lends itself readily to indefinite extension. The power and dynamos both being divided into like units, each independ-

dent of all the others, extension becomes merely a question of more units, without any special preparation in the plan.

First Cost of Plant.—This consideration, although really of the least importance among those enumerated, is distinctly on the side of subdivided power. The price of the high speed engine per horse-power is now fully as low, and generally lower, than that of slow-speed engines. Cost of foundation is materially less, as is also cost of erection and handling for repairs. Then there comes into the question the clear saving of all the money invested in countershafting, pulley blocks, heavy belting, clutch pulleys, pulleys, and similar devices. In the station to which we referred above, the extra transmitting devices necessitated the investment of a sum not less than \$6,500. The price thus expended would be sufficient to purchase practically 500 h.p. of independent engines, adequate to generate 6,000 lamps, showing practically net earning capacity of at least \$18,000 per annum. When we contrast this with the net losses due to the system of concentrated power, as above discussed, it leaves no room for argument as to the advantages of independent engines in electric light work.

ROYAL METEOROLOGICAL SOCIETY.

In connection with the exhibition, referred to in our Notes, two addresses were given on the evening of the opening day. The first was by the President of the Society (Dr. W. Marcet, F.R.S.), the subject being "Atmospheric Electricity." It was pointed out that the air is always more or less charged with free electricity of a positive or negative kind, and there is reason to believe that every single drop of fluid vesicle that goes to form a cloud is also coated with this subtle agent. Thus, when storm clouds charged with contrary electricity approach each other elongated sparks shoot from one to the other; and when, at last, by their mutual attractions and repulsions, or by the action of the wind, they are brought nearer to one another, lightning flashes in rapid succession illumine the sky and the roar of thunder is heard far and wide. In the same way, when a black storm cloud charged with positive electricity comes near the earth, the negative electricity which the globe contains is brought to its surface in a state of great tension, and then the two electricities fly towards each other and a flash of lightning is seen. The clap of thunder that follows is the noise of the violent reverberation of air rushing in to fill the vacuum produced by the intense heat of the electric spark. That lightning is nothing more than Nature's electric light, Dr. Marcet showed by producing on the screen magnified images of the sparks thrown off by an electrical machine. In this way the diffused or sheet lightning, with its comparatively straight beam, and the zigzag path of the forked lightning, were graphically exhibited. Dr. Marcet explained briefly the manner in which atmospheric electricity is believed to be concerned in the production of hail, waterspouts, and the aurora borealis.

The second address was by Mr. G. J. Symons, F.R.S., the title of whose paper was "The Non-existence of Thunderbolts, Elucidated by Accounts of Searches After Them." Mr. Symons has endeavoured to track the so-called thunderbolts wherever he could hear of them; but they have vanished before the man of science like ghosts before the daylight. His inquiries showed that there was no more transmission of a thunderbolt, or of any other solid body, when an electric spark rushed through the air, than there is the transmission of a material substance when a message is telegraphed across, or rather under, the Atlantic Ocean. Sometimes a lightning flash appears to strike the ground, and a spherical nodule of iron pyrites is found near the spot. It was there before. Still, the ignorant imagine it came from the clouds, and with the lightning. Belemnites, which are really fossil animals, are found similarly, and in "Webster's Dictionary" are described as "thunderstones," and as such are often preserved. Occasionally a heavy discharge of lightning falls on a bed of sand, penetrates it for several feet, and melts the siliceous in its path, fusing it into a kind of glass, which is known as fulgurite—some fine specimens of which are to be found in the British

Museum. This, and this only, could have any pretence to be considered a thunderbolt, but then it does not descend from the clouds, and is caused solely by the intense heat of the lightning. Mr. Symons did not deny that solid bodies do at times come down from the sky and strike the earth; but these are meteorites and aerolites—substances ejected from volcanoes or falling upon the earth from planetary space. They are always falling, but when accidentally they descend during a thunderstorm they are instantly designated thunderbolts, though the two phenomena have absolutely no connection. For the credit of Englishmen the lecturer hoped that henceforth the word thunderbolt would be erased from our dictionaries.

THE DISTRIBUTION OF ELECTRICITY BY ALTERNATE CURRENTS.*

BY T. CARPENTER SMITH.

The distribution of electricity by means of alternating currents, though comparatively new in this country, has already reached such an enormous importance, that it is with great hesitation that I venture to speak upon it, even though limiting myself to the strictly practical side of the work, dealing only with the apparatus as we receive it from the hands of the manufacturer, and leaving out entirely the question of the efficiency of dynamos and converters. It is only the knowledge that the mistakes of those who enter upon any new line of business are the rounds of the ladder by which we all attain success that emboldens me to lay before you some of the conclusions at which I have arrived, after several years' experience, of varied types of electric lighting, both by the arc, by the direct current incandescent, and the alternate current incandescent.

The subject naturally divides itself into several heads, but I would first say that it appears impossible to lay down any general plan of distribution, which shall be practicable in all cases. In almost every town a different plan will be required, and this will depend in most cases purely on local circumstances. Systems and methods that would be admirable for thickly settled and densely populated districts will not be successful in thinly populated and widely scattered ones. I wish it to be understood that whenever I speak in this paper of success and successful systems, I mean successful entirely in a commercial way, and the conditions of this commercial success will vary in every town and district. I will, therefore, content myself with describing the method which I have found to be most successful in the various districts with which I have had actual experience, and leave it for those who may be called on to design and lay out the lighting of any particular district to judge for themselves which line of action to pursue.

Naturally, the first part of my subject is the dynamo, and the station detail. I have tried the small and large dynamo, and have concluded that it is a very great point to properly proportion the unit size of dynamo to the probable size of the station; that is, not to have dynamos of different sizes, but to first determine what the unit shall be, making it as large as possible, and then make your whole apparatus additions to that unit size. This simplifies matters very much, enabling machines to be interchangeable, both as regards their parts and their work, and thus I am sure will be admitted by all who have ever had the annoyance of a breakdown on engine or machinery, when perhaps they had standing idle plenty of apparatus, which, from various circumstances, could neither be used itself nor be robbed to repair the breakdown.

I would drive each dynamo by a separate engine, and this for several reasons: By proportioning the engine to the dynamo it will be possible to have the engine running slightly overloaded when the dynamo is doing its utmost during the hours of heavy lighting; and as this extreme load falls off to the lighter hours of running, the engine will be working at its point of best economy, instead of running underloaded, and thereby wasting steam. Thus, we use in our station on Virgin Alley, dynamos of 2,500 lights capacity each, driven by 200 horse-power engines. During 16 hours of the day these dynamos run, driving 2,000 lights, and the engines are cutting off at quarter stroke, and developing 200 horse-power. During the other eight hours we have driven these dynamos as high as 2,800 lights, during which time the engine was of course overloaded, and not working to so good an economy, but eight hours' overload is not nearly so wasteful as sixteen hours of underload; again, we have had it very forcibly demonstrated more than once that if the engine be only large enough to drive the dynamo with ease, a heavy short circuit on the mains outside will simply pull the engine up or slow it down without destroying the dynamo, and only those who have seen a nine foot fly-wheel running at 250 revolutions per minute on a 200 horse-power engine, slowed

* Paper read before the National Electric Light Association, February 23.

in almost an instant of time, can realise the terrific which everything is subjected in such cases, and I mention right here that the element of time is a very poor in such circumstances, as, in an accident of this kind, is often done before the safety catches can melt in direct taking of the engine to the dynamo is always started; shutting is, except under exceptional circumstances a nuisance for incandescent electric-light stations, economy of one large engine over many small ones has seriously overrated. For fire-light work, where the light is all lit and extinguished at certain hours, the local is cut out of the control of the station, it is impossible to run a large engine at anything like its most economical speed, with separate engines, the machines can be started and the moment that they are needed or are done with, and from shifting will always cause more or less grease

in the station use, except for very small plants, I should use separately excited dynamos, and should do the from two or more dynamos, each capable of exciting the system. In this way, with the station running at its the only regulation required is that obtained by working a rheostat in the field of the exciter, and, as we have our station at Pittsburgh, this will mean the regulation of lights by one six inch hand wheel. Of course, each should have its separate field rheostat, to make up for a difference in speed of engines. The two exciters are arranged that they can be run together or separately, either can do the whole work, which of course is easily done by feeding them into a separate pair of exciter dynamometers from these. The general question as to it is better to use separate circuits for separate machines, or to run them into a general set of bus wires and distribute from, is too large to be lightly decided, as also is the question as to whether it is best to run separate circuits for districts, or to run into a general system of high pressure outside of the station, feeding into these mains at points, and again distributing from them, and I am not prepared to express any preference, but think that local forces will generally decide this question. There seems the doubt that in underground systems the network of pure mains would be the best, but for overhead work adopted the system of separate circuits from separate dynamometers, using a switchboard which enables us practically to connect or any number of circuits from any dynamometer, and these dynamos separately and not in multiple are of the utmost precautions, the unregenerate telegraph men are always hauling wires across our bare mains and feeders, and while their wires, and not hardly kinder, after hearing the frightful roar that comes from a dynamo which is running the particular circuit so we always feel relieved to know that only one dynamometer of being thrown out by the slipping off of the belt. Only much belt is not a pleasant thing to have flying loose. In case of any trouble, such as fire, circuit down, or anything of that sort, we can pull the switch particular circuit until we can cut out the part affected, so that I have had out for use here, will, of course, be true to introduce, in view of the fact that we are from one system to the other, and have to be governed by the location of our lighting, our existing lines, and ability of putting up additional pole lines, but it takes, then, the form of a series of heavy mains down the city, with cross lines on the cross streets, with switches placed, enabling any of the cross streets to be run from one or other of the main streets, so that, in case of a fire on one of the main streets, the section represented by the switch which the fire occurs can, by the pulling of two switches, be completely cut off, while the cross streets on either side of the section will enable the lights beyond the fire or street to be operated, with only the trouble of a slightly percentage of loss, and the consequent dimming of the

main overhead wires I must harp upon the old string, and be struck too often, namely, high insulation. For current work the old standard of "undertakers' wire" is but when it comes to 1,000 volts difference of potential, 130 or 140 amperes to back it up, one realises very that nothing is too good to curb this very speed. We paying the penalty of early ignorance in having many "undertakers' wire" stretched upon our poles, and I have listened with fear and trembling to the howls of a man, which had only been in operation for a few days, we had four short circuits as many minutes, and dead wires falling across these mains on a wet day. On the other hand, I have been gratified beyond expression our linemen remove ten or twelve old bare iron "cable" wires, which had been hanging all night right in high pressure, high insulation mains, and this during rain. Especially should the service wires to the con-

verters be of the best insulation, not only for fire but for protection to life; for, while the shock does not kill, even a 100 volt shock may make a man start so as to fall off a ladder, and any death or injury will be credited to the electric current. We have adopted a standard of a separation of three feet between the two wires nearest each other on our cross arms, and do not allow under any circumstances the tapping of service lines directly to these wires. All services must be attached through the medium of a small spreader on the end of the cross-arm, which I have no doubt all those present have noticed on the streets.

In some districts, where the number of lights in each building is small, we run secondary low pressure mains, and place the converters on the poles, and make our distribution from our secondary mains, but our experience has been that this is not a very satisfactory way of doing. The percentage of loss on these secondary mains, unless the wires are very large, or the converters very numerous, either of which is objectionable, causes such a decided variation in the lights as to give grounds for numerous complaints.

The question of the loss on the high-pressure feeders and mains is one which, I think, has not received enough attention. When the alternating system was first introduced, so much was said about the extreme smallness of the wire required that a great many of the arc light men throughout the country, who had been accustomed to congratulate themselves on the fact that No. 6 wire was big enough for a 20 mile circuit, immediately jumped to the conclusion that, because it was a high-tension current, No. 6 wire was big enough for all cases; and, consequently, more than one case of dreadful grief has arisen. I have laid out our circuits on a certain fixed plan, which is that each circuit should be laid out for 1,300 lights (that being the size of unit which we at first adopted), and made of such sizes as to carry these 1,300 lights with a loss of not more than 2 per cent. with the load on. By having feeders large enough for this, we prevent any noticeable difference in candle-power from one end of the circuit to the other; and should we be even compelled to run a light circuit and a loaded one on the same machine, the increase in the one or the decrease in the other would not be injurious. Of course, we try to so arrange our circuits that the load shall vary about the same on each, but the suddenness with which storms creep up in Pittsburgh makes our load very uncertain and erratic. We have run for three days and nights with only a little more than half of the machinery in operation, and then from Monday night to Friday morning have had to run every incandescent machine in the station under a load that fairly staggered it.

I now come to the question of the placing of the converters; and for this I think you may safely lay down the general rule that wherever you are simply carrying current, do it at high pressure, and keep your low pressure for the purely local distribution. With proper precautions, I do not see that there is any real danger in carrying the high pressure wires into and through the building. If a thousand-volt current from a central station is not to be allowed in a building on account of its dangers, then every arc light plant, whether from central station, or an isolated plant in the building, must be condemned for the same reason. Of course, the cases where two wires of an arc circuit, with a difference of potential of 1,000 volts, are run close together, are not nearly so many as must be the case where there is a constant difference of potential of 1,000 volts in the alternating system; and again, of course, we have the fact that the direct current on arc circuits is generally not more than 20 amperes, while, as I have remarked before, our alternating currents run as high as 130 amperes, but the fact that one is a direct, and the other an alternating current, largely makes up for this difference. With all due respect for the many gentlemen who have discussed so learnedly on the deadly alternating current, and on the frightful results therefrom, and whose experience with the alternating system is mostly confined to the magneto bell, or induction coil, I must maintain that the alternating current, while it is in mild doses of from one hundred to two or three hundred volts intensely more disagreeable than the direct current of the same voltage, when it comes to 1,000 volts, or more, it is very much less dangerous to life. I make this statement with the more confidence that I have tried them both, and we have in our station here not one, but half a dozen cases where our linemen and dynamo men have received the full 1,000 volts, generally being pretty badly burned at the point of contact, but experiencing no ill after-effects; while, whenever any of our men receive a shock from one of our arc machines they are nearly always sick for a day after. This very fact of the alternating current being more disagreeable adds to its safety, as the men are disinclined to work on the wires, even when there is only a slight leak, where with the direct current they will often take much greater risks. In carrying our high-pressure wires through the buildings, we have adopted the invariable rule that they must be carried on porcelain insulators, and the wires themselves waterproof, in all cases. We do not allow them to be run in moulding, but where the wires are to be concealed, or protected, a casing is run around the wires outside of the porcelain insulators, giving them a perfect air

insulation, and hard rubber must always be used for floors and walls. The converters are all placed with porcelain knobs behind them, giving an air space of two inches between them and the wall; and we prefer, in all cases, to put them against brick, rather than against wood or plaster. I understand that in some districts the use of converters inside buildings has been forbidden, but I think that this position is a most unjust and untenable one. The only argument that can be brought against their being placed inside is the danger to life or of fire. For the first, the converter is well insulated, and is placed high up out of reach, and most potent argument—though one, I am sorry to say, often refused recognition—it is not placed there to be handled. As regards the danger from fire, all the converters with which I have had any experience are boxed up completely in iron cases, the only opening in which is a small one at the bottom for ventilation. They cannot possibly get hotter than the melting point of lead, for the simple reason that if they should the fuses would blow out and cut them out of the circuit, and any one who has performed the old experiment of melting lead in a piece of paper can easily see that this heat is not liable to set any thing on fire, and even should the converter burn out no flame can escape from it to set fire to anything, however inflammable. If the converter is to be banished from buildings on account of danger from fire, then every stove, high pressure steam pipe, and for that matter every gas jet must also be banished.

In a Chinese firecracker lately published I find the statement that Inspector McDevitt has relegated to the cellar all converters, and that he says that in the first case of explosion or fire from them they will have to go to the street. Now, as vice-president of the company owning these converters, I have simply to say that this is not so, and that the converters are placed all through the buildings, wherever we may desire to have them, and only three or four are in cellars. Moreover, so far from Mr. McDevitt making any such statement, he has steadily refused, even under the most urgent solicitation of the Chinese gentlemen, to make any such restriction, but has very properly stated that until an explosion or fire occurred he can take no such action. I speak of the publication as a "firecracker" for three reasons: first, because it is red; second, it is chiefly noise; third, a good many crackers are only fizzes.

As regards the liability to burn out, and the danger therefrom, I can only say that from over 600 converters of all sizes, from five to fifty lights each, in an experience extending over twelve months of constant service night and day without any stop, we have had but three actual cases of burning out, two of these being five-light converters, and one being a fifty-light converter. The two five-light converters were simply slowly roasted out from overloading, until finally the insulation on the primaries was charred through, when the fuses blew out instantly, and all was over. In one case the customer had been attracted by the converter singing, and was standing looking at it when his lights suddenly went out, and he had to go into a neighbour's store to know whether the trouble was in his lights only or with the main circuit. The fifty-light converter suffered in the same way, having nobly endeavoured for some two days to run 120 lights. It was one of three on a section of secondary mains, and the lineman who had been sent out to examine them, owing to complaint to us of poor light, reported that two of them were all right, as they were cold, but that one of them was bad, as it was very hot, and preparations were being made to change this converter, when a message was received from one of our customers that the "stove on the pole" in front of his place was smoking.

Investigation showed that both plugs in the other two converters were blown, and the only reason that this one had not followed suit was the fact that some ingenious gentleman had made them of copper. We have had three cases of defective converters—that is, converters with a wire broken inside, or short circuited, so that the moment that the current was put into them they would blow out all the fuses, and if new fuses were put in they would again blow; but the men in these cases, of course, immediately returned them to the shop for examination. That is to say, out of the 600 converters we have actually had to remove or repair 1 per cent in actual service; and I submit that, on a total converter capacity of 17,000 lights, this is a very good proof that these converters are well made and not dangerous.

In all of our experience we have not had one single case of connection between the primary and secondary, or the primary and the shell of the converter, even in the case of the burned out converters, and we had, just a few days ago, the first case of a connection between the secondary and the shell of the converter.

We started in with the idea that it was better in cases where we had, from the number of the lights in a building, to use more than one converter, to bank them; that is to say, connect all the primaries and all the secondaries in multiple, and distribute from this bus wire; but two or three peculiar experiences have led us to change our plans, and never to do so if it can be easily avoided. We had two or three unfortunate cases where one converter of a bank, for some unknown reason, would blow

its plugs, thus overloading the others; then, perhaps, it would give way, and thereafter it was a race as to which blow its plugs the quickest. It is not calculated to make me feel comfortable to have 400 lights in a theatre go out as just as the curtain was about four feet from the stage, beginning of the third act; yet this was our experience Christmas day. We had the converters fused up and in half an hour, but next day the same thing occurred; the gas man, seeing the lights dim down, was quick and shutting off his different circuits to stop three or four converters which gave him lights enough to pull through. We had this building up, and each converter now carries its own with the result of our detecting one of them, which, for reason unknown, always tried to do more than its share work; but while we have marked it, we have not troubled to change it, as, working singly, it does its work well. We had another case of the same kind in another bank of converters, which have also since been cut apart, when the trouble arose from a poor connection, which heated to fuse to melting point; yet, as we have in the City Hall station a bank of twenty-three 40-light converters and 20-light converters, which have never had the current of for nearly three months, and have never had a single one of all these blow its fuses, we cannot say that this result always or even generally obtain; but as the object of it is primarily to prevent the total extinction in case of one converter going out, and this is better attained by the junction of the secondary circuits, we prefer keeping the converters separated.

For the secondary wiring in the buildings, we need no laws. The rules governing this are too well known to need repetition. One advantage of the alternating system, was first brought to my attention by one of our wiremen, fact that wires carrying the alternating system do not heat the surface on which they run. We have in our station of direct and alternating currents side by side, put up some time, on a ceiling painted in very light colours, and have been burning the same number of hours. The paint on the direct current wires is very dirty, in the usual style, the wires themselves are covered with a black deposit, while alternating current wires, and the ceiling on which they are, as clean as the day when they were put up.

There yet remains one point on which I wish to say words, and it is a subject of the greatest importance. No alternating current distribution is a pronounced fact there is no reason why the places of all others where descent light is most desirable, namely, in residences, do not enjoy the advantages and improvements from which have hitherto been debarred by their distance from the centre of distribution, and it is when we bring electricity to the dwelling house, where it will be daily and hourly, and handled by women and children, that we realize how utterly necessary it is that we use anything and everything can tend to make safe its introduction and manipulation. The first, second, and third of these are—good and better insulation, and best insulation, but besides this there are other points to be considered, and one that seems to be of very careful consideration, and the fullest discussion which has been more than once suggested, namely, the of a permanent ground connection with the secondary. The object of this, of course, is that should a leak occur point between the primary and the secondary, the current already grounded will render it impossible for any one to a shock by touching the secondary, and at the same time an earth connection. When I first considered this question said in my haste that this was not a proper course of action one is simply provoking a ground at some other point, seeing the careful insulation of the converters we use, I not see any danger of a leak across; but I have since in my mind not come to any conclusion at all until I have considered and heard some discussion both *pro* and *con*, and purpose I should like to hear the most bitter partisans of side, that we may get from them every little weakness of side of the question brought out.

In a paper like this it is impossible to do more than a mere sketch of the subject, but I trust that what said may be the means of inviting discussion and inquiry is only by this means that we can arrive at the true facts case, and, as we all know, the electric light industry has more than tongue can tell from the general ignorance of dangers and requirements, which hindered and injured its introduction into this country, and which led to the spending so much good money on plants and wires which were not sufficient, but absolutely dangerous.

Now that we have taken, as it were, a new departure entered upon a new era of progress, let us not fall into the errors which marred the early history of our business, but with might and main, by discussion and interchange of views, to make each new installation another stride towards perfection in what I think is undoubtedly the greatest achievement of the age—the distribution of electricity by alternate

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS—STUDENTS' MEETING.

A students' meeting was held on Friday last, the 16th inst., Mr. W. M. Mordey presiding.

Mr. Mordey made some remarks in regard to arbitrary units, and explained the system adopted by the Anglo-American Brush Electric Light Corporation for numbering wires and leads.

Mr. A. H. Dykes then opened a discussion upon transformers, which was sustained by Messrs. Smith, Lamp, Cooper, Tidd, Collis, Ziegler, and Mordey.

The meeting then terminated after passing a vote of thanks to the chairman.

LEGAL INTELLIGENCE.

INFRINGEMENT OF TELEPHONE PATENTS.

A motion for an injunction on behalf of the United Telephone Company was made on March 15 before Mr. Justice Chitty, to restrain the Equitable Telephone Company from infringing the patents for telephones of the plaintiff company. The United Telephone Company being proprietors of the patents for telephones in which carbon is used, have established their right in the patent in the course of several actions, and the instruments are in general use, rented from the plaintiff company.

The defendant company was registered, with a small capital, in December, 1886, for the manufacture and sale of telephones, but they wrote to the plaintiff company, stating their intention to manufacture and sell the articles, which they invited the plaintiffs to inspect at the offices of the company, where it was tried up. The plaintiffs took no notice of the letter. In December, 1887, and February, 1888, when the plaintiffs found the company were at work, they bought two of the instruments, alleged by the defendants to be made according to their patent, and asserted by the plaintiffs to be an infringement of their patent. It was this instrument of which it was sought to restrain the manufacture and sale. It was said that the defendants were endeavoring to force the plaintiffs to bring another action to try over again the validity of their patent, notwithstanding the judgments already given in its favour. The defendants opposed the present motion on the ground of delay, arguing that as the plaintiffs knew in 1886 what the defendants were doing they ought to have come to the court sooner. By an affidavit of the manager of the plaintiff company it was sworn that they did not take steps against the defendants because it was thought the defendant company was a harmless company, and that the notice was only a threat, but as soon as they found the company was in active operation they brought this action.

Mr. Justice Chitty said the plaintiffs were entitled to the injunction they sought, and that there had not been delay on their part. Undertakings in damages were given by both the plaintiffs and defendants.

PROVISIONAL PATENTS, 1888.

MARCH 9.

3670. A volt indicator. Alexander Siemens, 28, Southampton-buildings, Chancery-lane, London, W.C.

3672. Means or appliances for use in connection with electric circuits or water or gas supplies or the like, to enable a supply of electricity for lighting or other purposes, or a supply of water or gas, or the like, to be obtained on the deposit of an equivalent therefor in the shape of prepayment or otherwise. Henry Edmunds, 47, Lincoln's Inn-fields, London.

3678. Improvements in and relating to electrical signalling on railways and in apparatus therefor. Wybrants George O. Clarke, Gray's Inn Chambers, 20, High Holborn, London, W.C. (Complete specification.)

3685. Improvements in electrical switches. Sidney Sharp, Julian Messy Vernon Money Kent, and Henry John Payne, 70, Chancery-lane, London, W.C. (Complete specification.)

MARCH 10.

3690. Improvements in railway electrical signalling apparatus. Edward Dunn, 21, High-street, Forebridge, Staffordshire.

3710. Improvements in electro-magnetic motors. John Tweeddale, 87, Vincent-street, Glasgow.

3714. Improvements in electric fittings. Arthur Cecil Cockburn and Frank Day, Cleveland-house, Aubert Park, Highbury, N.

3766. An improved form of communicator and collectors for dynamo-electric machines and electric motors. George James Baldwin, 14, Carthew-road, Hammersmith, London, W.

MARCH 12.

3812. An improved combined switch and holder for electrical incandescence or glow lamps. Ernest Lower Berry and Gustave Franke, Gray's Inn Chambers, 20, High Holborn, London, W.C.

MARCH 13.

3841. Improvements in telephonic apparatus. Thomas Laurie, 115, St. Vincent-street, Glasgow.

MARCH 14.

3920. An improved process for coating iron and steel with tin. John Thornton, 71, Evesham-street, Rolditch.

3921. Improvements in apparatus for indicating, measuring, and controlling electrical currents. Thomas Parker, Edmund Scott, Gustave Rees and John Harold Woodward, 70, Market-street, Manchester.

3929. Improvements in and relating to dynamo-electric machines. Thomas Parker, Edmund Scott, Gustave Rees, and John Harold Woodward, 70, Market-street, Manchester.

3968. Regulation of feed of arc lamps. John William King, 15, St. John's-square, Clerkenwell, London.

3979. Improved construction of plates and arrangement of fastenings for connecting them in voltaic order for medico-electric purposes. William George Johnson, 166, Fleet-street, London.

3981. Improvements in and connected with means for driving, controlling, and working electrically propelled vehicles, cranes and the like. Edward Hapkinson, 47, Lincoln's Inn-fields, London.

3986. An improvement in plates for secondary voltaic batteries. Bernard Mervyn Drake and John Marshall Goddard, 28, Southampton-buildings, Chancery-lane, London, W.C.

MARCH 15.

3995. Improvements in and relating to galvanic batteries. Henry Harris Lake, 45, Southampton-buildings, London. Hugo Walter, United States. (Complete specification.)

3998. An improved electrical indicator for the locking apparatus connected with railway points. Thomas Charles Roberts Horsfield and Robert Porter, 31, Essex-street, Strand.

4008. Improvements in electric batteries. Harris Ullathorne and Charles Gaudes, 20, Chancery-street, Bradford, Yorkshire.

4017. Improvements in electric arc lamps. George Edensor Dorman, The Hawthorns, Newport-road, Stafford, Staffordshire.

COMPLETE SPECIFICATIONS ACCEPTED.

DECEMBER 11, 1886.

16,275. Improvements in dynamo-electric machinery. Edmond Desroziere, 47, Lincoln's Inn-fields, London, W.C.

MARCH 26, 1887.

4545. Improvements in electrical measuring and indicating apparatus. Charles Denton Abd, 20, Southampton-buildings, Chancery-lane, London, W.C. (The firm of Siemens and Halske, Germany.)

MARCH 29, 1887.

4714. Improved electrical signal bell apparatus for stations communicating with a single-wire telegraphic circuit. Francis Alexandre Amore, 28, Southampton-buildings, Chancery-lane, London.

APRIL 7, 1887.

5185. Improvements in brush holders for dynamo electric machines. Alexander Pelham Trotter and Walter Thomas Goulden, 23, Ambulus-road, Clapham, London, S.W.

5210. Improvements in automatic apparatus for subjecting the person to the action of electric currents. Auguste Serrallier, 8, Quabty-court, Chancery-lane, London, W.C.

MAY 2, 1887.

6409. Improvements in dynamo-electric machines and motors. Rookes Evelyn Bell Crompton and William Augustus Kyle, 55 and 56, Chancery-lane, London.

MAY 6, 1887.

6681. Improvements in secondary batteries or electrical accumulators. Rookes Evelyn Bell Crompton, Arc Works, Cheshamstead, Essex, and John Charles Howell, Cardiff, Glamorgan.

MAY 19, 1887.

7317. Improvements in secondary electric batteries. James Kynoch and William Habgood, 7, Bank-buildings, Church-street, Camberwell.

JUNE 8, 1887.

8262. Improvements in and pertaining to electric generators. William Morris Mordey, 46, Lincoln's Inn-fields, London, W.C.

SPECIFICATIONS PUBLISHED.

1887.

2563. Electrical primers. G. Stuart. 8d.

2598. Electric gas lighters. T. P. Hewitt. 8d.

5096. Dynamo-electric machinery. G. Kapp. 8d.

5404. Automatic signalling apparatus for railways. T. H. Richardson. 8d.

5404A. Automatic fog-signalling for railways. T. H. Richardson. 8d.

5485. Internal combustion thermo-dynamic engines. J. Hargreaves. 8d.

5583. Galvanic batteries. H. Liepmann. 8d.

6346. Electrical apparatus for preventing corrosion of steam boilers, &c. A. T. Marquand. 8d.

10,057. Extracting aluminium from its fluorides by electrolysis. E. De Passy, Bernard. 8d.

1888.

100. Generating electricity. H. H. Lake. (Humans.) 11d.

623. Thermo-electric elements and piles. R. J. Guichet and L. Pintsch. 8d.

COMPANIES' MEETINGS.

GERMAN UNION TELEGRAPH AND TRUST COMPANY.

The seventeenth ordinary general meeting of the German Union Telegraph and Trust Company (Limited) was held on the 19th inst. at Winchester House, Old Broad street, Sir James Anderson in the chair.

The **Chairman**, in moving the adoption of the report and the payment of a dividend (tax free) of 8s. 3d. a share making with the previous distribution a total dividend of 14s., or at the rate of 7 per cent. per annum compared with 6 per cent. for the previous year) reminded them of what he stated at their last meeting as to the offer of the German Government for the purchase of the Company's cable. They considered the offer somewhat favourable, but there was a good reserve, about £25,000, representing the distribution of which they felt that they would like to know a little more. With that view, and feeling that a portion of that sum might be obtained for the shareholders, their solicitor (Mr. Best), their secretary (Mr. Payson), and himself went to Berlin last month, and he was glad to state that after a little warm discussion they left that city about £10,000 better off. They at the same time made arrangements as to the rent of the Berlin office, the expenses of liquidation, the stamps, and, in fact, about every item that their solicitor and secretary thought was likely to tip into the reserve. They could now state with some accuracy that they believed if all went well the shareholders would receive within 1s. or 1s. 6d. of par, dependent, of course, on the expenses of repairs and breakages which might happen between now and next year. One cable was now broken, but the "Britannia" was on the spot waiting for two or three fine days to effect the repair, which he had no doubt would be easily done. After the payment of the dividend now proposed there would be no more dividend until January next, when he believed the shareholders would receive about three-fourths of their capital back, and the usual distribution of capital would be in April. That was perhaps the last meeting but one of their Company. He regretted that it was to be wound up, because it was going on very well, but as the German Government would not have a private company working the traffic, they had to put up with the offer which had been made to them.

Mr. H. G. Erickson seconded the motion, which was unanimously adopted, and the retiring director and auditor were re-elected.

CITY NOTES.

Western Union Telegraph Company.—The Western Union Telegraph Company has declared a quarterly dividend of 1½ per cent.

National Telephone Company.—The registered offices of the National Telephone Company (Limited) will be removed on the 24th inst. to 102a, Queen Victoria-street, E.C.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company, Limited, for the half month ended March 15, are £3,333, which compared with £3,278 for the same period last year, show an increase of £55.

Removal.—The London offices of Messrs. B and G. Shorthouse, manufacturers of wire for telegraphic and telephonic purposes, have been removed to Mansion House Chambers, 11, Queen Victoria-street. Messrs. Apperly and Stove, submarine and electrical engineers, are the sole London agents for this firm.

Brazilian Submarine Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the past week amounted to £4,979, and those of the Western and Brazilian Telegraph Company, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,181.

Eastern Telegraph Company.—The Eastern Telegraph Company announce the payment, on April 14 next, of a dividend of 3s. per share on the preference shares of the Company, less income-tax, for quarter ending March 31, 1888, and an interim dividend of 2s. 6d. per share on the ordinary shares of the Company, free of income-tax, in respect of profits for the quarter ended December 31, 1887.

Direct Spanish Telegraph Company.—The report of the Direct Spanish Telegraph Company, Limited, for the half year ended December 31, states that, after putting £2,500 of the balance of profit and loss to the reserve fund, which now amounts to £8,447, there remains £3,064 available for dividends. The directors recommend the payment of a dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend of 2½ per cent. (free of income-tax) for the half-year upon the ordinary shares, making, with the previous distribution, 4 per cent. for the year 1887, and to carry forward £16s.

NOTES.

Greece.—The Athens-Pireus-Peloponnesus Railway Company has adopted the telephone for the transmission of signals on all its lines.

Indian Telegraphs.—A telegraph line is to be laid from Darjeeling to Kalimpong. A light fieldwire may also be laid onwards to the Rilli River.

International Telegraph Stations. According to the *Journal Télégraphique* of Berne, the total number of international telegraph stations throughout the world amounts to 57,000.

Attributed to Electricity.—The recent alarm of fire at Lord Brassey's residence, 24, Park lane, is said to have been caused by a spark from the electric converter setting fire to the wood casing.

Spain. According to the *Industria e Invenções*, the Government intends to lay a new cable between Spain and the Balearic Islands. The undertaking will probably be entrusted to a foreign company.

Italy.—The Italian administration of telegraphs has superseded the Wheatstone automatic instruments by the Hughes instrument on the lines between Rome and Palermo, and between Naples and Palermo.

Paris Exhibition. The *cahier de charges*, or conditions of contract, for the lighting of this exhibition has recently been published, and may be obtained on application to the Society of Telegraph-Engineers and Electricians, 4, the Sanctuary, Westminster.

Torquay.—Wherever they are prepared to give more money for a better light than gas or oil, there the electric light has a chance. It is about to have a chance at Torquay, where the inhabitants have resolved in public meeting to form an electric light and power company for the town.

United Telephone Company.—This company having passed six wires across the Lewisham District Board's stone arch at Forest Hill, and having also laid some underground wires in the neighbourhood of Forest Hill Station without sanction, the Board have requested that such wires may be removed.

Electric Lighting at Mans. A central distributing station has been opened at the Rue des Planches in this town. Crompton dynamos are employed, capable of working 100 Swan lamps. Schenck and Farbaki accumulators are employed as regulators, and with a view to obviate any accidental breakdown of the lighting.

Astute Foreign Gas Companies.—At the last general meeting of the shareholders of the Reims Gas Company, full powers were given the directors to continue the negotiations already commenced with the municipality for the installation and distribution of the electric light. Similar action was taken at the last meeting of the Verona Gas Company.

Munich.—The municipality have decided to establish electric lighting in the basements of the Hotel de Ville, which comprise a large restaurant. The undertaking, which had been placed in the hands of Messrs. Schuckert, has finally been entrusted to the Electrical Company at Munich. It has also been decided not to renew the contract between the town and the gas company, which terminates in 1899.

Fire-alarm Signals. The Stockport Watch Committee invite tenders to provide and erect fire-alarm signalling apparatus, consisting of electric bells and telephones. For particulars apply to Superintendent Buck, Police Office, Stockport. Tenders, endorsed "Tenders for Fire-Alarms," should be delivered to Mr. W. Hyde, town clerk, by 10 a.m. on the 6th prox.

Italy.—The town of Terni will shortly inaugurate its installation for electric lighting. The motive power is derived from three turbines, each of 160 h.p., constructed by the firm of Ganz in Buda Pesth. Each turbine will drive a Ziperowski dynamo. The present number of lamps is 300. The lighting of the Italian Exhibition, to be opened next month at Rome, has been undertaken by A. Belloni and Co., of Milan.

Batsford Park.—The stables just completed for Mr. A. B. Freeman Mitford, at Batsford Park, have been lighted by electric light, which illuminant is also to be used in the mansion now in course of erection. The machinery is 250 yards from where the light is produced, and the current is carried by an underground cable across the park. The number of lights in the stables is 75, mostly 16 and 8 candle power lamps.

Devonshire.—We hear that steps are to be taken to call a public meeting at Newton, following upon that at Torquay, with a view to introducing electric lighting into the town. It is pointed out as unfortunate circumstances that nearly the whole of the members of the Local Board are gas shareholders, and that the original shareholders in the gas company are getting at the present time 30 to 40 per cent. on their investment. At the same time complaint is made of the comparatively high price of gas in this locality.

The "Electrical Review."—Our New York contemporary in entering upon its 13th volume appears in what may be termed a new dress, in that its cover has a somewhat striking appearance, the front being covered by an elaborately designed illustration, indicative of the electrical industry. Our American contemporaries take credit for smart and go-ahead productions, and we have no reason to complain of them on that score. The contemporary to which we have specially referred claims consideration for its enterprise, and we have no doubt it is highly appreciated by its large circle of readers.

Distribution by Accumulators.—The first central station for the distribution of the electric light by means of accumulators has recently been inaugurated at 37, Neue Friedrichstrasse, at Berlin. The installation includes two steam engines, each of 35 h. p., and two kilo-watt dynamos. The accumulator employed is that of Khotinsky, of which each element (1 cell) is stated to have a capacity of 600 ampere-hours. The incandescence lamps are those of Seel, taking 150 volts. The most important consumer, so far, has 500 lamps, installed in a restaurant. The total cost of the central station and main leads amounts to 89,500f., which gives 175f. per lamp.

An Electric Lamp for Farmers.—The following hint for electricians is taken from a transatlantic paper:—"Among possible applications of electricity to domestic uses there is one which does not seem to have yet attracted the attention of scientific instrument makers. That is an electric lamp for farmers. At present the husbandman in the country employs either the familiar horn lantern invented by King Alfred and a tallow dip, or the more modern glass lantern,

burning benzoline or petroleum. The former gives a wretchedly dim light, while the latter is difficult to light and extinguish, and is, moreover, very unsafe to carry about in linchays filled with straw. An electric lamp would not only give a bright light, but would be absolutely safe."

Compressed Air.—A company, with a capital of 1,800,000*fr.*, has been established at Lyon for the storage and distribution of energy by means of compressed air. Central works are to be established analogous to those in operation in the Rue St. Fargeau at Paris. This "*Compagnie Lyonnaise de l'air comprimé*," to which M. Popp is the consulting engineer, has obtained from the municipality a concession extending over forty years, during the first five of which their rights are exclusive, for the house-to-house distribution of motive power. It seems improbable that this company will obtain a greater measure of success than has been realised by the Paris establishment, in other words, their outlook is not very encouraging.

Bournemouth.—At a recent meeting of the Roads Committee a letter was read from Messrs. Phillips, Harrison, and Hart, asking permission to lay down their cables along the roads. It was recommended that a committee of the whole board be called to consider the matter. The Clerk, at the recent meeting, read another letter from the same firm, stating that they only required immediate permission for taking up the roads leading from the Arcade and Town Hall-avenue to their works in Orchard-lane, and that they would like to be allowed to transfer the permission to the Bournemouth Electric Light Company, which was recently formed. The recommendation to refer the former application to a committee of the whole board was agreed to, and the latter question was similarly dealt with.

Conductivity of Nitric Acid.—It has been shown by M. Bouty that the addition to fuming nitric acid of very minute proportions of an alkaline nitrate has the effect of considerably augmenting the electrical conductivity of the liquid. Continuing his researches in this direction, the same investigator points out that, up to a certain point, the addition of water to the concentrated acid increases its conductivity almost in the proportion of the quantity of water added. The addition of small proportions of dehydrating substances, such as concentrated sulphuric acid or anhydrous sulphurous acid, has the same effect, apparently by reason of the production of electrolytic compounds of sulphuric or phosphoric and nitric acids. Lastly, M. Bouty has demonstrated that nitric acid in different stages of dilution does not contain the same electrotype.

The Van Rysselberghe System in Switzerland. This system of rendering a wire adaptable for the simultaneous transmission of telegraphic and telephonic messages, by an application of the law of electro-magnetic inertia, has not hitherto been a success in Switzerland; and the results there obtained render it questionable whether it has in reality proved successful elsewhere. The system was adopted experimentally by the Swiss Government on the Bâle-Zurich line, and the results are stated to have been so unfavourable that the idea of applying it to other lines has been relinquished, and, in spite of the large expense involved, it has been decided to establish special lines for inter-urban telephony. Moreover, the establishment of this means of communication between Bâle and Zurich, in substitution for the Van Rysselberghe arrangements, is under consideration.

Pender and Co.—"We have been waiting to see some protest against the proposed banquet to Sir John Pender. Sir John Pender is an expert and successful cable jobber, and as cable jobbing is a business that conduces to the prosperity of the jobbers, by all means let them dine each other. But when a pretence is made that a scientific interest attaches to such a gathering we enter our objection. With the view of getting a representative meeting together, invitations to the banquet have been sent out broadcast to all sorts of scientific men, several of whom have written to us saying that they have nothing whatever to do with the affair. The promoter appears to be Sir James Anderson, whose profession coincides very largely with that of Sir John Pender. Well, let Sir James Anderson and Sir John Pender drink each others' healths if they will, but do not let us have speculation masquerading in the guise of science."—*Star*.

Bremen.—The authorities of this town have entered into an arrangement with the "*Allgemeine Elektricitäts-Gesellschaft*," of Berlin, for the installation of a central station for the supply of the electric light. In consideration of an annual payment of 1.25*fr.* for each lamp worked from the station, the town has conceded to the Company the right to establish overhead or underground wires in the streets as it may think fit. The subscribers will pay about 5½ centimes per hour per lamp of 16 c.p. The station will be capable of working 10,000 lamps. The subscribers are to defray the cost of the lamps and of the installation in their houses; but the Company reserve the right of refusing to supply any subscriber whose installation has not been carried out by Messrs. Siemens and Halske, to whom the execution of the work has been entrusted. The same Company possesses at Hamburg a small station supplying 1,500 incandescence and several arc lamps.

Electric Railway. A project, which has obtained the approval of the *Conseil d'Etat*, has been mooted for the construction of a "rack and pinion" electric railway about 6 kilometres in length, between the village of Etroubles, in Savoy, and the plateau of Grand Salère, from which the view extends on one side to Geneva, the Jura, and Lemman, whilst on the other it embraces the panorama of the great Alps. This project is of interest, not only to the localities to be traversed, but also to the City of Geneva, and to the tourists of all nationalities who flock thither every year. One of the clauses of the agreement stipulates that the concessionaires are to supplement the line, when constructed, by another starting from Vevy, and ascending the Swiss slope by the passage known as the *Pas-de-l'Echelle*. This would obviate the inconvenience to the inhabitants of Geneva and to tourists of having to travel a considerable distance to the Etroubles terminus in order to ascend to the Salère by the railway.

Railway Carriage Lighting. Since the commencement of the year, experiments have been made on the State railways in Alsace on the electric lighting of the trains. The current is supplied from a small battery of accumulators situated beneath each carriage. Each battery consists of 36 couples; and the batteries are charged at several stations supplied with an installation for lighting which is thus utilised during the daytime. The capacity of the batteries is 40 ampere hours—presumably under an E.M.F. of 72 volts. No details are given as to the weight of the batteries. The plates are said to be constructed with a frame of lead carrying a certain number of vertical lead rods about 3 millimetres in diameter, expanding at intervals into the form of a thin disk about 9mm.

diameter. Each carriage is lighted by 5 Seel lamps of 10 c.p., taking under 60 volts a current of from '5 to '6 ampere. The conductor of the train can regulate the light by means of a small resistance-coil in the vicinity of the battery. The work has been carried out by the Société Alsacienne d'Electricité at Strasbourg.

Electric Lighting of Trains.—On Tuesday morning a number of gentlemen interested in the lighting of railway carriages by electricity left St. Pancras Station by the ten minutes past ten train, on the invitation of Mr. John Noble, managing director of the Midland Railway Company, to visit Derby, and to witness the working between that town and Manchester of the system of electric lighting of railway carriages patented by Mr. J. A. Timmis. The chief feature of the system is that it secures "through lighting" in a train by the adoption of the Union battery stored in each vehicle, and by this means any carriage may be put into a siding, or be slipped from a train without interfering with the maintenance of the light. In case one or more of the vehicles are slipped or break loose from a train, the lamps in them, if lit, remain lighted, and if they are not lit provision is made for their being automatically lighted up. The chief feature of the arrangement is in what is termed the controlling circuit, by means of which the guard can switch the lights on or off at will, though at all times the state of the lighting circuit is such that, should a carriage break away, the lamps are automatically lighted. The lamps used are 5 candle power Swan lamps, two to each carriage, and these are arranged below reflectors, that aid in the equal distribution of light through the whole carriage.

The Burning of the Oporto Theatre.—Our apprehension as to the probable extent of the loss of life, consequent upon the destruction by fire of the Baquet Theatre, has been only too fully confirmed. The number of bodies exposed for identification amounted to sixty six, and besides these there were fifty three unrecognisable masses, which could be distinguished as human remains, and for the reception of which the municipality is constructing a marble mausoleum. The electric light has been utilised to enable workmen to continue their search for bodies by night as well as by day. The account given of the origin of the catastrophe sounds horribly familiar to our ears.—"So far as can be ascertained, this disaster arose from an unprotected jet of gas being blown by a draught against the scenery. A scene-shifter named Davas saw it, and tried to lower the curtain, so as to shut out the flames from the auditorium, but as he was rushing forward some burning scenery fell down on the stage. The public became panic-stricken, and made a simultaneous and violent rush for the doors." The theatre was formerly a circus, and was constructed mainly of wood. Of course, "the gas went out suddenly," and in the narrow passages the fresh terror and danger of darkness fell upon those who had struggled beyond the glare of the flames. Is it too much to hope and to expect that a similar catastrophe will never again be due to the selfsame cause?

Encyclopædia Britannica.—The current volume of the Encyclopædia Britannica contains several very interesting articles to electricians. The longest and more important ones are those contributed by Mr. T. Gray, who is now contributing to our own columns, on the telegraph and telephone. In the former the author first gives an historic sketch of early telegraphs, mentioning the several people who suggested the various forms of telegraphs actuated

by static electricity, and we are glad to see that the brothers Highton are mentioned. The work of these gentlemen is frequently overlooked. Then we have a general description of electric telegraphy for land and sea, followed with the various tests employed, especially in cable work, concluding with a description and explanation of the instruments used in modern telegraphy, such as the Morse instrument, the Hughes type-printing, and briefly referring to duplex and quadruplex work so far as land working is concerned. Nor are the beautiful instruments of Sir William Thomson used in telegraphy overlooked, but are sufficiently explained, so that the casual reader may understand the principles upon which their actions depend. The method pursued in the article on telephony is somewhat similar to that pursued on telegraphy, giving first a brief historic *resumé*, then describing the various instruments and their improvements somewhat in the order of their invention, concluding with a discussion on telephonic circuits and the method of working their circuits. Altogether Mr. Gray has contrived to get a very considerably amount of interesting information into a comparatively small space.

The Central Station at Saint-Etienne.—According to the *Bulletin International de l'Electricité* the gas company at Saint-Etienne has taken proceedings against the municipality of that town in relation to the establishment there of a central station for electric lighting. This action, however, has had no detrimental effect upon the new undertaking; indeed, the uninterrupted flow of applications from intending subscribers has necessitated a considerable augmentation of the plant. The initial installation comprised four Edison dynamos of 400 amperes; the number has now been increased to seven, of which one is maintained in reserve, the remaining six being arranged in three groups of two in series. These are capable of supplying 3,000 lamps of 16 c.p., which actually corresponds to a considerably greater number of lamps, since many of these are of 10 c.p. only. The three-wire system of distribution is to be adopted; and the cables formerly employed are to be replaced by bars of copper; the three bars in each group of conductors being kept apart by insulators of dried and bituminised wood and inserted in iron pipes, which are afterwards filled with a melted mixture composed of 70 parts of asphalt, 15 of paraffin, and 15 of rosin. The motive power disposable at the Saint-Etienne works is at present 600 h.p.; it is supplied from four steam engines each of 150 h.p., and would be capable of supplying 6,000 lamps of 16 c.p. The financial results of the undertaking promise to be of a satisfactory character, although no dividend has yet been declared. The works have been in partial operation since January, 1886.

Incandescent Lamps.—Mr. Hosea E. Husted, in the *Electrical World*, writes on the subject of why lamps blacken. He says:—"In considering the above question, and as the result of experiment, I have come to the following conclusions: First, if we take an incandescent lamp globe and fill it two-thirds full of a mixture of equal parts of turpentine, alcohol and benzine, and seal up the opening, then heat it to 100deg. F., and let it stand, we will find the oil will ooze out of the pores. The reason of this is that in heating, the glass globe expands and lets the thin oil through the pores. In manufacturing these globes the filament is placed in them and the air is extracted, creating a vacuum. Without this the carbon would be consumed the instant the electrical current passes into it.

After a time a black deposit will be noticed upon the inner surface of the globe, due to a separation from the filament. If a globe that is blackened be jarred, it will emit sounds as of two pieces of steel struck together. These sounds are due to the presence of air in the globe, as the following experiments will prove: Place a bell under a globe, create a vacuum by a pump and try to ring the bell. The armature will vibrate and strike the bell, but no sound will be emitted. Now, allow a small quantity of air to pass in and the sound will gradually increase as the air is admitted. Hence, I conclude, that by heat and atmospheric pressure the vacuum has ceased to exist in the globe, and by the presence of air the carbon is consumed, giving off a gas or vapour which is deposited upon the glass and blackens it." We cannot say that we agree with all the conclusions of the observer we have quoted.

More Light.—Looking back nearly a century and a half, our contemporary *Electrician* takes note of the continuously increasing demand for a higher degree of illumination—a demand which has only recently met with anything like a corresponding supply. In 1745, on the occasion of a festival given in the *Salle des Glaces*, at Versailles, the guests were fain to content themselves with a lighting effect corresponding to 2.5 candles per cubic metre, or 0.19 candle per square metre of plane surface. In 1788, in the *Salle des Fêtes* at Compiègne, a less lofty hall, the illumination had been raised to 2.3 (73.6) candles per cubic metre, corresponding to 0.28 candle per square metre. In 1873 and 1878, in the same hall of the Graces, the lighting was increased respectively to 8.3 and 16.7 candles per cubic metre, or to 0.64 and 1.30 candle per square metre. Within a century, therefore, the illumination has been augmented more than six fold. In the electric lighting of the grand opera, the illumination of the *foyer* was 11.3 candles per cubic metre or 0.63 candle per square metre. Taking the mean illumination, this amounts to 4 carcel metres or about 30 candle metres. This means that on any surface, taken in any direction, the illumination is the same as would be given by the concentrated light of 4 carcel burners at a distance of a metre. This was excessive, or at least relatively so; for the theatre itself, in which it was impossible to produce such a flood of light, seemed dark by contrast, and for this reason the former illumination has been diminished. At the *Hotel de Ville*, during the festivals of the present year, the illumination, which in the *salon de verdure* and reserved hall was only about 4.4 candles per cubic metre, was raised to 14 and even 15 candles in the *salle des fêtes*, the dining room, the grand saloons and the side gallery.

Electro-Harmonic Society.—A smoking concert is announced for Friday, April 6, 1888, at the St. James's Hall Restaurant (Banquet Room), to commence at eight o'clock. The artistes are Mr. Robert Hilton, Mr. Arthur Thompson, Master Humm, elocutionist, Mr. Charles Fry, violins, MM. Jacques Greebe and T. E. Gatehouse; viola, Mr. W. Hann, violoncello, Mr. W. C. Hann, solo piano-forte and accompanist, Mr. Alfred Izard. The following is the programme:—Part I.: String quartette, "Allegro Moderato" (minueto and trio) (Haydn), MM. Greebe, Gatehouse, W. Hann, and W. C. Hann; new song, "Oft I Wander" (Lovett King), Mr. Arthur Thompson, recitation, (a) "The Glove and the Lions" (Leigh Hunt), (b) "A Tragedy in Five Acts" (Anon), Mr. Charles Fry; song, "Nymphs and Shepherds" (Henry Purcell), Master Humm; duet for two violins,

"Introduction and Rondo" (Kalliwoda), Mr. T. E. Gatehouse and Mr. Jacques Greebe, piano Mr. Alfred Izard; recit. and air (*La Reine de Saba*), "She alone charmeth my sadness" (Gounod), Mr. Robert Hilton; string quartette, "Andante Cantabile" (Mozart), "Minueto and Trio," "Allegro Moderato," MM. Greebe, Gatehouse, W. Hann, and W. C. Hann. Part II.: Duet for two violins, "Schlummerlied" (Ch. Ersfeld), Mr. T. E. Gatehouse and M. Jacques Greebe, piano Mr. Alfred Izard; song, "The Sands o' Dee" (F. Clay), Mr. Arthur Thompson; recitation, "The Gridiron" (S. Lover), Mr. Charles Fry; song, "The Diver" (E. J. Loder), Mr. Robert Hilton; piano solo (selected), Mr. Alfred Izard; song, "The Children's Home" (F. H. Cowen), Master Humm; string quartette, "Adagio Cantabile" (Haydn), "Finale Vivace," MM. Greebe, Gatehouse, W. Hann, and W. C. Hann.

The City Lighting.—The following suggestion is made by our contemporary the *Journal of Gas Lighting*. It is good as far it goes; but, of course, practically assumes there is a sufficiency of light from existing gas lamps. We, on the contrary, contend there is a deficiency. Here is what is said:—"It is to be supposed that the Streets Committee of the Commissioners of Sewers of the City of London are still deliberating upon the details of the competitive offers of electric light companies for lighting the City streets, which are generally believed to have been submitted to them. It should not be asking too much to request the Committee, before going any further in this matter, to appoint a Technical Commission, consisting (say) of their own engineer (Mr. W. Haywood, M.I.C.E.) and gas examiner (Mr. C. Heisch, F.I.C., F.C.S.), with an independent authority, to draw up a report upon the general question of the lighting of the City thoroughfares. The matters which could be referred to such a body might be the cost and efficiency of the existing method of lighting the streets. They should ascertain the actual amount of light afforded by the gas-lamps in use, and give their observations upon its sufficiency or otherwise from the points of view of public security, traffic, and trade. They might compare the lighting of the City with the public lighting of other busy centres of trade. The requirements of different thoroughfares as affected by the nature and course of traffic, the number and character of crossings, the amount of extra illumination from shop windows, and the time of closing business establishments, should also be taken note of. Then, if an increase of light is found desirable anywhere, the best and cheapest way of providing it would be shown by comparisons in which reliable photometry and true figures would be used. The result of the labours of such a commission would be to settle the data upon which contracts for new systems of lighting may be safely based. The practice actually in vogue is the contrary of this plan, being merely to receive suggestions for supplanting so many gas lanterns by electric lamps, without anybody knowing whether the change is likely to result in better or worse lighting for practical purposes. There is not much probability, however, of this suggestion being adopted, because it is too sensible."

Lighthouses and Coastguard Stations.—The *Western Morning News* publishes a letter from Mr. J. G. Uren, of Penzance, which strongly urges the necessity of bringing the above within speaking distance:—"Ever since the loss of the 'Schiller,' says Mr. Uren, 'I have been endeavouring to impress on the public the extreme importance of having our lighthouses and coastguard stations

connected with the telegraph system of the country. Above all, I earnestly protest against the matter being looked upon solely in its financial aspect. It is easy enough to show that no direct return could be had for the capital expended. The same may be said of our troops and our warships, our guns and our fortresses. Yet nobody advocates that the country should be left defenceless. So in this matter is it nothing to avert disaster? to aid in the saving of life and property? and to protect our coasts from Sicily to the Hebrides with a cordon of sentinels in touch with the great arsenals of the kingdom, and ready at any moment to direct our efforts on any point which may be threatened by an enemy? Suppose it does cost a million or so—not millions but tens of millions have been spent in far less worthy causes—and are we to be told that a great maritime power like England, whose supremacy depends on the command of the sea, is to shrug its shoulders and raise the cry, 'it won't pay,' when even our colonies are setting us the example, and other countries with not a tithe of the interests at stake are showing us the way? I hope it is not necessary to give any further examples of the utility of this great work, but I cannot help referring to the case of the Brixham trawler lost off the Gurnard's Head last week. She was seen to be in distress, with the crew at the pumps, and one hand lashed to the mast. She was followed from point to point, and foundered, in fact, within view of many who would have been only too glad to render assistance had the appliances been at hand. There was a lifeboat and rocket apparatus on either side of her—at Sennen and St. Ives yet neither was aware of her danger. Immediately, at Pendennis and the Gurnard's Head, there are coastguard stations, and in all human probability, had they been able to communicate promptly with their brother officers at Sennen and St. Ives, five valuable lives would have been saved. This is only a solitary instance of what is going on round our coasts year after year."

Taunton and Exeter.—The following letter appeared in the *Exeter Gazette* recently, in reply to an article which appeared in that paper, copied from the *Gas World*, severely criticising the Taunton Electric Light Company:—Sir: Owing to absence from home, I have only just received a copy of your paper of the 13th inst., containing a criticism of the Taunton Electric Light Company, copied from the *Gas World*. I was certainly astonished that even a journal devoted to gas interests should make so inaccurate and misleading a statement. As I see by your issue of the 14th inst. that Mr. J. Knill has kindly supplied your readers with the correct figures, I will not trouble you with them. The annual reports and balance sheet of the Taunton Company have been audited by a gentleman who commands the respect of all who know him. He is a director also of the rival lighting Company (the Taunton Gas Company). Copies of these reports have been freely circulated in Taunton, and it would appear that each of the journals devoted to gas interests has obtained one, judging from the opportunities they appear to have for criticising. But they have been obliged to bless where they intended to curse, for in each instance their condemnation is in reality commendation. The only fault they can find with the Company is that its costs of management are too small, and that had its officers been paid on an extravagant scale instead of an economical one, it would have been unable out of its nett income to pay a dividend of 5 per cent. per annum upon the whole of its share capital, and carry forward a balance equal to an additional 2 per cent. I admit that "An Electric Light Company earning a dividend of 5

per cent. upon the mere supply of lights is a curiosity in this country, and in this respect occupies an exceptional position." But I must remind *Gas World* that there must be a beginning to everything, and the experience of the pioneer gas companies differs very little, if at all, from that of the pioneer electric light companies. I certainly feel complimented by the statement of *Gas World* that "the Electric Light Company in Taunton would, in all probability, have gone the way of other similar Companies but for the Herculean efforts of Mr. H. G. Massingham, who assumes the function of managing director." As I have accepted a similar position with respect to the Exeter Electric Light Company, I trust that my efforts will be no less "Herculean" on behalf of that Company also, and that they will be attended with the same happy results to the shareholders.—I am sir, yours, &c., H. G. Massingham. Bath, March 17th, 1888.

The Proposed Central Stations in Paris.—The obnoxious *cacher des charges*, or conditions of contract, relative to the construction and working of central distributing stations in Paris, is still under the consideration of the Municipal Council of that city. It is understood that its adoption would have the effect of almost precluding all enterprise in the direction of electric lighting; and, amongst the projected undertakings of which it would effectually prevent the execution, are the following, which are referred to in the report of M. Lyon-Alemand to the Electrical Committee:—The Continental Edison Company have put forward a proposal to establish a canalisation, extending from its works at Ivry to the Place de l'Opéra, *via* the Rue de Patay, the Rue Jeanne d'Arc, the Rue Geoffroy-Saint-Hilaire, the Boulevard St. Germain, the Boulevard Saint-Michel, the boulevard de Sebastopol, and the grand boulevards, returning by the Rue de Rivoli; these mains serving also for the production of the light in the Place de la République and the Rue de Turbigo. —The electric apparatus and lighting company (Cance Company), the central works of which are situated at 7, Rue du Faubourg Montmartre, proposes to supply the grand boulevards, from the Rue Mazagran to the Rue de la Chaussee d'Antin, together with the surrounding streets, as far as the Rue Cadet, the Rue Geoffroy-Marie, and the Rue Sainte-Cécile, inclusively, in one direction, and as far as the Bourse in the other direction. —The French Company of Electric Lighting (Mildé and Clere) proposes to extend its network from the Porte Saint-Martin to Place de la Madeleine, including in its operations a portion of the Boulevard de Strasbourg, of the Boulevard de Sebastopol, and of the Faubourgs Saint Martin and Saint-Denis, a portion of Rue Montmartre, the Rue du Faubourg Montmartre, and the surrounding streets, and, lastly, the district surrounding the Opéra.—M. Pulsford applies for a concession over 774 metres of the Boulevard de Strasbourg, the Boulevard Saint Denis, the Rue du Faubourg Saint Martin, and the Rue du Château d'Eau.—Lastly, the company for the electrical transmission of force (M. Marcel Deprez) proposes to establish its leads from the *gare du Nord* to the Grand Hôtel, *via* the Rue Lafayette and the Rue de la Chaussee d'Antin; connecting this line through the grand boulevards to another line supplying the *Bourse du Commerce*, and passing through the Boulevard de Magenta, the Boulevard de Strasbourg, the Boulevard de Sebastopol, and the Rue de Turbigo. —To the above might be added the proposed municipal works in the basements of the Halles, which, besides supplying the market buildings, was to light the Hotel de Ville quarter.

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, B.Sc., F.R.S.K.

[All rights reserved.]

(Continued from page 248.)

Calibration of Wires.—It is not always possible to obtain wires of perfectly uniform section, and it is still more difficult, when alloys like German silver or platinoid are used, to obtain wires of perfectly uniform electrical resistance. It is important therefore to have some ready means of testing the electrical uniformity of the wires to be used for the wire slide in a Kirchhoff's or similar bridge. The following method will be found convenient and sufficiently accurate for a preliminary test of the wire before it is soldered into the bridge. Let *W*, Fig. 14, be a piece of the wire to be tested. Join it between two binding screws *A*, *B*, or solder it to the heads of two wood-screws fixed in a table or piece of board. Connect up in circuit with the wire a battery *E*, introducing into the circuit a key or break circuit plug *P*. On one side of a block of dry or paraffined wood, or vulcanite, *C*, fix two springs *a*, *b*, five or ten centimetres apart, measured between two knife edge contact pieces soldered on the lower sides of the springs. Cut a narrow V groove parallel to the edge of the block *C*, and place the edge of the block far enough under the wire to allow the wire to rest in the groove, with the contacts attached to the springs resting on the top of it. Join the electrodes of a high resistance and sensitive galvanometer, *G*, to the two springs, *a*, *b*, and note the zero of the galvanometer. Close the circuit of the battery, *E*, and note the deflection of the galvanometer after it has become constant.

FIG. 14.

There will be a slight variation at first, due to the heating of the wire by the current. Then slide *C* slowly along the wire, and observe whether there is any change of deflection. If there is no change, the wire is so nearly uniform that this method is not sensitive enough to show the variations. If there is a change, the wire may be calibrated by noting the galvanometer deflection at different points along the wire. The curve of variation along the wire can be clearly shown by plotting the results of the experiment on section paper, divided, say, to tenths of an inch, and drawing a smooth curve through them. Suppose, for example, that the deflection of the galvanometer was about 500 scale divisions, and that it varied a few divisions backwards and forwards; we may take any line on the section paper for the 500 line, and using one division of the paper as one scale division plot the variation from 500 above and below the line, using for abscissa lengths along the wire from one end, reduced to a convenient scale. The sensibility of the method here indicated may be increased either by increasing the current through the wire, or by increasing the sensibility of the galvanometer, and using what has sometimes been called a "false," and sometimes an "inferred," zero for the galvanometer. In this method the deflection of the galvanometer needle is brought approximately to the zero of the scale by means of a permanent magnet, placed with its length horizontal and at right angles to the length of the needle when in its zero position. This is equivalent to deflecting the needle when no current is flowing off the scale in the opposite direction from that in which the current deflects it. The effective zero may be inferred by varying the distance between *a* and *b* by a measured fraction of the total distance, and observing the change of deflection. This change of deflection will be the same fraction of the total deflection as the change of distance between *a* and *b* is of the total distance between them. The deflection may be reduced to zero by means of a coil placed with its plane parallel to that of

the galvanometer coil, either the position of the coil, or the strength of the current through it, being varied until zero deflection is obtained. The current through this second coil may be obtained either from an independent battery, or, which is better, it may be obtained from a different part of the wire which is being calibrated. This method of compensation suggests at once a differential galvanometer as a convenient instrument for the test. The electrodes of one coil of this galvanometer should be connected to two points near *A* or *B*, and the same distance apart as the contacts of the springs *a*, *b*. For use in this way it is very convenient to have one of the springs *a* or *b* mounted on a fine screw, by means of which the distance between the contacts can be varied. The total value of the deflection, which would be obtained if the current through coils connected to *a* and *b* alone flowed, can then be found by turning the screw through such a distance as to give a convenient deflection. If the displacement of the spring due to turning the screw be *d*, the total distance between the contacts *d*, the deflection due to turning the screw *D*, and the total deflection *D*, then

$$D = D_1 \frac{d}{d_1}$$

The slider may then be drawn along the wire and the deflections noted, and put down in the form of a curve as indicated above, or the deflections may be always reduced to zero by means of the screw, and the percentage variation of the wire estimated from the step and number of turns of the screw and the total distance between the contacts. It is, as a rule, quicker, and quite as accurate, to leave the screw fixed and read the galvanometer deflections.

The following method of calibrating a wire has been

FIG. 15.

described by Prof. Carey Foster, and is commonly known as Foster's method. It is intended to divide a wire into sections of equal resistance, and it is capable of doing so with great exactness. Let *w* be the wire to be calibrated. Connect it in series with a battery *E*, as shown in Fig. 15, and arrange a second wire *w*₁ in a convenient position relatively to *w*, so that the two wires may be connected in parallel by means of the connecting pieces *g* and *c*. The resistance *g* is called the gauge, and it is convenient for it to be a definite fraction of the resistance *w*₁ + *g*, say a tenth of that resistance. The connecting piece *c* generally has, and is here assumed to have, so small a resistance that it is negligible compared with *g*. The connections should be made by means of mercury cups at *A*, *B*, *C*, *D*, so as to avoid error due to resistance at these points. The mode of operation is as follows:—Connect one electrode of a galvanometer, *G*, to the mercury cup *D*, and find the point *a* on *w* at which, when contact is made, the galvanometer needle is not deflected. Next keep the contact at *a* and interchange *g* and *c* and then find the point *b* on *w*₁ at which, when contact is made, the galvanometer shows zero deflection. Proceed in this way by interchanging *g* and *c* and finding alternately points on *w* and *w*₁, as indicated by the dotted lines in the figure, until the end of the wire, *w*, has been reached.

It is clear that the successive steps along *w* and *w*₁ are equal: because, after balance has been obtained with the galvanometer connected from *D* to *a* a resistance of *g* - *c* is transferred to the other end of the bridge, and hence a resistance *bD* equal to *g* - *c* must be passed over before balance can be again obtained, and this is the case for each step along *w*₁, hence *w*₁ is divided with equal steps. Again, *aB* is the same fraction of *AB* that *g* is of *c* + *w*₁ + *g*, and *bD* is the same fraction of *AB* that *bD* + *g* is of *c* + *w*₁ + *g*, that is, since *bD* = *g*, when *c* is negligible, *bD* is twice *aB*, and so on. When *g* - *c* differs sensibly from *g*, the first

B is greater than the succeeding ones, and for that it is generally preferred to make w_1 the wire to be used. There is, however, the advantage in the here indicated that c_1 , w_1 , and g , may form a permanent piece of apparatus for the x_1 and w_1 may be made of comparatively high resistance either by making it a thin wire or by doubling it times backwards and forwards, gridiron like, and making it long. The gauge g can then be made of resistance that if c be a thick U of copper its resistance may be neglected. In carrying out this method care is taken that the ends of g and c are clean and well coated, and that they make contact directly on the of the cup so that no mercury resistance is introduced. The ends of g should be thick pieces of copper so that variation in the quantity of mercury in the cups does not affect the resistance. The continual interchange of c is apt to lift globules of mercury out of the cups and read them over the board on which the wires are laid, and care must be taken that these do not touch w_1 if they are of a material that amalgamates with it.

Following modifications of Foster's method possess advantage that no mercury cups need be used, and the in the wire circuits are all permanently made and soldered. Let w , Fig. 16, be the wire to be used, and w_1 an auxiliary wire. Connect the ends C, either directly, or by means of a connecting piece the ends B and D by means of a small resistance g . Put one of the battery electrodes to A, and the to the lever of the key K, and the front and tops of the key to the points B and D respectively. When of the key K the battery may be put to B or D

FIG. 16.

will of the operator, the resistance of the connecting and the key contacts being always in the battery.

With the battery to D, and one electrode of the meter to B, find the point b which has the same potential as B. Then, with the battery to B, and one electrode of the galvanometer to b , find the point a which has the same potential as b , and so on. The steps along AB in this case, equal to each other, but they have a constant ratio; and hence, if it is simply the uniformity of the wire which is to be tested, this method serves the purpose perfectly. If it is desired to divide the wire up into steps of equal resistance, it may be done by calculation on the results of this experiment; but a more convenient method for this purpose is described below. It should be remembered, in the practical use of this method, that the wire is first put to the end of the wire to be calibrated; if not done, the first step is not in the regular series of others. Thus B D, together with the gauge g , form a step of the series along w_1 . The relative values of the steps along either of the wires may be readily as follows. Let x_1, x_2, x_3, \dots be the successive steps along w , and y_1, y_2, y_3, \dots those along w_1 ; and let the resistance of w and w_1 be R and R_1 respectively. Then we may apply Ohm's law, or by the ordinary Wheatstone's bridge method,

$$\frac{y_1}{R_1 - y_1} = \frac{g}{R} \quad \text{or} \quad y_1 = \frac{R_1}{R + g} g \quad (1)$$

In the same way we obtain

$$y_2 = \frac{R_1}{R + g} (g + x_1) \quad \therefore \text{by (1)} \quad y_2 = \frac{R_1}{R + g} x_1 \quad (2)$$

$$y_1 + y_2 + y_3 = \frac{R_1}{R + g} (g + x_1 + x_2)$$

$$\therefore \text{by (1) and (2)} \quad y_3 = \frac{R_1}{R + g} x_2 \quad (3)$$

Similarly we have

$$\frac{x_1}{R - x_1} = \frac{y_1 + g}{R_1 - y_1} \quad \text{or} \quad x_1 = \frac{R}{R_1 + g} (y_1 + g) \quad (4)$$

$$x_1 + x_2 = \frac{R}{R_1 + g} (y_1 + y_2 + g) \quad \therefore \text{by (4)} \quad x_2 = \frac{R}{R_1 + g} y_2 \quad (5)$$

$$\text{Hence by equation (2)} \quad x_2 = \frac{R R_1}{(R_1 + g)(R + g)} x_1 \quad (6)$$

$$x_1 + x_2 + x_3 = \frac{R}{R_1 + g} (y_1 + y_2 + y_3 + g)$$

$$\therefore \text{by (4) + (5)} \quad x_3 = \frac{R}{R_1 + g} y_3$$

$$\text{Hence by equation (3) and (6)} \quad x_3 = \left\{ \frac{R R_1}{(R_1 + g)(R + g)} \right\}^2 x_1 \quad (7)$$

&c., &c. Hence we have

$$\frac{x_1}{x_2} = \frac{x_2}{x_3} = \dots = \frac{y_2}{y_3} = \dots = \frac{y_1 + g}{y_2} = \frac{(R_1 + g)(R + g)}{R R_1} \quad (8)$$

From equation (8) we see that the length of these successive steps along the wire w and, with the exception of the first, along w_1 form a geometric series having the common ratio $\frac{R R_1}{(R_1 + g)(R + g)}$. The proper value of this fraction and the uniformity of the wire can be readily found by plotting the results in the form of a curve in a similar manner to that explained above.

In order to obtain steps of equal resistance along the wire by this method two gauges g of equal resistance are used to connect the two ends of the wires w and w_1 . A

FIG. 17.

convenient arrangement for the purpose is shown in Fig. 17. Two keys, K and K_1 , are placed side by side, and the battery is connected to the levers as shown. The front stop of K is connected to C, and the back stop of K_1 to D, and, in the same way, the front stop of K_1 is connected to B, and the back stop of K to A. Thus, when the levers of the keys are similarly placed, the battery is either joined across from C to B or from A to D. Join it in the first place from A to D, and find the point b which has the same potential as B, then join it from C to B, and find the point A which has the same potential as b , and proceed in this way until the point A is either exactly or nearly reached. The resistances from B to a , a to d , &c., will be all equal. Let, as before, the resistances of the successive steps along w be x_1, x_2, x_3 , &c., and those along w_1 be y_1, y_2, y_3 , &c., and let the resistance of the wire w be R , and that of w_1 be R_1 . Then we have

$$\frac{y_1}{R_1 - y_1} = \frac{g}{R} \quad \text{or} \quad y_1 = \frac{R_1}{R + g} g \quad (1)$$

$$\frac{y_1 + y_2}{R_1 - (y_1 + y_2)} = \frac{g + x_1}{R - x_1}$$

$$\therefore y_1 + y_2 = \frac{R_1 + g}{R + g} (g + x_1) \quad \text{and by (1)} \quad y_2 = \frac{R_1 + g}{R + g} x_1 \quad (2)$$

&c., &c. Similarly we have

$$\frac{x_1}{R - x_1} = \frac{y_1 + g}{R_1 - y_1} \quad \text{or} \quad x_1 = \frac{R + g}{R_1 + g} (y_1 + g) \quad (3)$$

$$\text{Hence by (1)} \quad x_1 = \frac{R + R_1 + 2g}{R_1 + g} g \quad (4)$$

$$\frac{x_1 + x_2}{R - (x_1 + x_2)} = \frac{y_1 + y_2 + g}{R_1 - (y_1 + y_2)}$$

$$\therefore x_1 + x_2 = \frac{R + g}{R_1 + g} (y_1 + y_2 + g) \quad \text{and by (3)} \quad x_2 = \frac{R + g}{R_1 + g} y_2$$

$$\text{Hence by (2)} \quad x_2 = x_1 \quad (5)$$

Similarly it may be proved that $x_3 = x_1$, and so on. Hence, by equation (4) we see that the wire w is divided into sections,

which have each the resistance $g(R + R_1 + 2g)(R_1 + g)$. When R is equal to R_1 , the sections have each the resistance $2g$ —that is to say, the sum of the resistance of the two gauge wires, and as R_1 is increased the resistance of the sections diminish approaching nearer and nearer to g .

(To be continued.)

SIMPLE ELECTRIC MOTOR.

BY GEO. M. HOPKINS.

It is generally understood that an efficient electric motor cannot be made without the use of machinery and fine tools. It is also believed that the expense of patterns, castings, and materials of various kinds required in the construction of a good electric motor is considerable. The little motor shown in the engravings was devised and constructed with a view to assisting amateurs and beginners in electricity to make a motor which might be driven to advantage by a current derived from a battery, and which would have sufficient power to operate an ordinary foot lathe or any light machinery requiring not over one man power.

wound in even layers, and when the winding is complete the spool and its contents should be placed in a hot place and allowed to remain until the shellac melts and the convolutions of wire are cemented together. After cooling iron wire ring, B, is within from the spool, and covered with a single thickness of adhesive tape, to insure insulation.

The ring is now spaced off into twelve equal divisions and lines are drawn around the ring transversely, dividing it into twelve equal segments, as shown in Fig. 3. Wedge-shaped pieces, C, of hard wood are notched and fitted to the ring so as to enclose a space in which to wind the coil. This coil consists of No. 16 cotton covered or magnet wire, four layers deep, each layer having eight convolutions. The end, *a*, and the beginning, *b*, of the wire terminate on the same side of the coil. The last layer wire should be wound over two or three strands of thread, which should be tied after the coil is complete thus binding the wires together. When the first section of the winding is finished, the wire is cut off and the ends (about two inches in length) are twisted together to secure the coil to retain its shape. After the completion of the first section, one of the pieces, C, is moved to a new position and the second section is proceeded with, and so on.

FIG. 1. Simple Electric Motor (about half size).

The only machine work required in the construction of the motor illustrated is the turning of the wooden support for the armature ring. The materials cost less than four dollars, and the labour is not great, although some of the operations, such as winding the armature and field magnet, require some time and considerable patience. On the whole, however, it is a very easy machine to make, and if carefully constructed will certainly give satisfaction. Only such materials as may be procured anywhere are required. No patterns or castings are needed.

Beginning with the armature, a wooden spool, A (Fig. 2), should be made of sufficient size to receive the soft iron wire of which the core of the armature is formed. The wire, before winding, should be varnished with shellac and allowed to dry, and the surface of the spool on which the wire is wound should be covered with paper to prevent the sticking of the varnish when the wire is heated, as will presently be described. The size of the iron wire is No. 18 American wire gauge. The spool is $2\frac{1}{2}$ in. in diameter in the smaller part, and 2 in. in length between the flanges. It is divided at the centre and fastened together by screws. Each part is tapered slightly to facilitate its removal from the wire ring. The wire is wound on the spool to a depth of $\frac{1}{2}$ in. It should be

the twelve sections are wound. The coils of the ring are then varnished with thin shellac varnish, the varnish being allowed to soak into the interior of the coils. Finally, the ring is allowed to remain in a warm place until the varnish is thoroughly dry and hard.

Care should be taken to wind all of the coils in the same direction, and to have the same number of convolutions in each coil. A convenient way of carrying the wire through and around the ring is to wind upon a small ordinary spool enough wire for a single section, using the spool as a shuttle.

The ring is mounted upon a wood support or hub, and is held in place by the wooden collar, H, both hub and collar being provided with a concave flange for receiving the inner edges of the ring. The collar, H, is fastened to the end of the hub, G, by ordinary brass wood screws. The hub and collar are mounted on a $\frac{1}{2}$ in. steel shaft formed of stubs wire, which needs no turning. A pulley is formed integrally with the collar, H. The end of the hub, which is provided with a flange, is prolonged to form a commutator, and the terminals, *a* and *b*, of the ring coils are arranged along the surface of the hub and inserted in the holes drilled in the hub in pairs. The wires are arranged so that one hole of each pair receives the outer end of

coil, and the outer hole receives the inner end of the next coil, the extremities of the wire being scraped before insertion in the holes. The distance between the holes of each pair is sufficient to allow a brass wood screw to enter the end of the hub, G, and form an electrical contact with both wires of the pair, as shown in Fig. 1.

There being twelve armature sections and twelve pairs of terminals, there will of course be required a corresponding number of brass screws. These screws are inserted in the end of the hub, G, so as to come exactly even with the end of the hub. This completes the armature and the commutator.

is secured to a base board, G, as shown in Fig. 7, and grooves are made in the edges of the block, and corresponding holes are formed in the base to receive wires for temporarily binding the iron strips together. Opposite each angle of the block, F, mortises are made in the base board, G, to receive the keys, *d*, and wedges, *c*. Each key, *d*, is retained in its mortise by a dovetail as shown in Fig. 8. By this arrangement, each layer of the strip of iron may be held in position as the formation of the magnet proceeds, the several keys, *d*, and wedges, *c*, being removed and replaced in succession as the iron strip is carried around the block, F. When the magnet has reached the required

FIG. 3.

FIGS. 7 AND 8.

FIGS. 2, 4, 5, AND 6

Before proceeding to mount the armature shaft in journal boxes, it will be necessary to construct the field magnet, as the machine must, to some extent at least, be made by "rule of thumb." The body, E, of the field magnet consists of strips of Russia iron, such as is used in the manufacture of stoves and stove pipe. The strips are 2 1/2 in. wide, their combined length being sufficient to build up a magnet core 1/2 in. thick, of the form shown. The motor magnet has 15 layers of iron in the magnet, each requiring about 26 in. of iron; approximately, 33 feet altogether. The wooden block, F, on which the magnet is formed,

thickness, the wedges, *c*, are forced down so as to hold the iron firmly, then the layers of iron are closely bound together by iron binding wire wound around the magnet through the grooves, *c*, and holes in the base board, G.

The next step in the construction of the machine is the winding of the field magnet. To insure the insulation of the magnet wire from the iron core of the magnet, the latter is covered upon the parts to be wound by adhesive tape or by cotton cloth attached by means of shellac varnish.

The direction of winding is clearly shown in Fig. 9. Five

layers of No. 16 magnet wire are wound upon each section of the magnet, the winding of sections 1 and 2 being oppositely arranged with respect to each other. In like manner the winding sections 3 and 4 are oppositely arranged. The winding of section 1 is also opposite to that of 3, and that of 2 is opposite to that of 4. The winding begins at the outer end of the magnet, and ends at the inner end of the section. When the winding is completed, the temporary binding is removed. The outer ends of 1 and 2 are connected together and the outer ends of 3 and 4 are connected. The inner ends of 2 and 4 are connected. The inner end of 3 is to be connected with the commutator brush, *f*. The inner end of 1 is to be connected with the binding post, *g*, and the binding post, *g*, is to be connected with the commutator brush, *f*.

The field magnet is now placed upon a base having blocks of suitable height to support it in a horizontal position. A block is placed between the coils to prevent the top of the magnet from drawing down upon the armature, and the magnet is secured in place by brass straps, as shown in Fig. 1.

The armature is wrapped with three or four thicknesses of heavy paper, and inserted in the wider part of the field magnet, the paper serving to centre the armature in the magnet. The armature shaft is levelled, and arranged at right angles with the field magnet. The posts in which the armature shaft is journalled are bored transversely larger than the shaft, and a hole is bored from the top downward, so as to communicate with the transverse hole. To prevent the binding of the journal boxes, the exposed ends of armature shaft are covered with a thin wash of pure

FIG. 9.

clay and allowed to dry. The posts are secured to the base, with the ends of the armature shaft received in the transverse holes. Washers of pasteboard are placed upon the shaft on opposite sides of the posts, to confine the melted metal, which is to form the journal boxes. Babbitt metal, or, in its absence, type metal, is melted and poured into the space around the shaft through the vertical hole in the post. The journal boxes thus formed are each provided with an oil hole, extending from the top of the post downward. If, after cleaning and oiling the boxes, the shaft does not turn freely, the boxes should be reamed or scraped until the desired freedom is secured.

All that is now required to complete the motor is the commutator brushes, *f f*. They each consist of three or four strips of thin hard rolled copper curved as shown in Fig. 4, to cause them to bear upon the screws in the end of the hub, *G*. The brushes are secured by small bolts to a disc of vulcanised fibre, or vulcanite, at diametrically opposite points, as shown in dotted lines in Fig. 5, and the brushes are arranged in the direction of the rotation of the armature. In the brush-carrying disc is formed a curved slot for receiving a screw, shown in Fig. 6, which passes through the slot into the post, and serves to bind the disc in any position. The disc is mounted on a boss projecting from the inner side of the post concentric with the armature shaft. The brushes are connected up by means of flexible cord, as shown in Figs. 1 and 9. The most favourable position for the brushes may soon be found after applying the current to the motor. The ends of both brushes will lie approximately in the same horizontal plane. When the motor is in operation the direction of the current in the conductor of the field magnet is such as to produce consequent poles above and below the armature.

Eight cells of plunging bichromate battery, each having one zinc plate 5 in. by 7 in., and two carbon plates of the same size, will develop sufficient power in the motor to run an ordinary foot lathe or two or three sewing machines.

The dimensions of the parts of the motor are tabulated below.

Length of field magnet (inside)	10 in.
Internal diameter of polar section of magnet	3 1/2 in.
Width of magnet core	2 1/2 in.
No. of layers of wire to each coil of magnet	5
No. of convolutions in each layer	34
Length of wire in each coil (approximate)	95 ft.
Size of wire, Am. W. G.	No. 16
Outside diameter of armature	3 1/2 in.
Inside diameter of armature core	2 1/2 in.
Thickness	1/8 in.
Width	2 in.
No. of coils on armature	12
No. of layers in each coil	4
No. of convolutions in each layer	8
Length of wire in each armature coil (approximate)	30 ft.
Size of wire on armature, Am. W. G.	No. 16
Length of armature shaft	7 in.
Diameter of armature shaft	1 1/2 in.
Distance between standards	5 1/2 in.
Total weight of wire in armature and field magnet	6 lb.

PUMPING IN MINES BY ELECTRICITY.

We have several times referred to the use of electricity in mines for pumping purposes, and more especially to the very successful work of Messrs. Immisch and Co.; but all previous work has been insignificant beside the pumping plant which Messrs. Immisch and Co. have now laid down at Messrs. Locke and Co.'s, St. John's Colliery, Normanton, of which, by the courtesy of Messrs. Immisch and Co., we are able to give the following information: This new plant is designed to cope with a salt-water feeder of 5,100 gallons per hour, at a vertical depth of nearly 900 ft. below the surface. It was decided to raise the water at one lift, and at a rate of about 7,200 gallons per hour, so that the pumps could stand, if necessary, for six hours out of the twenty-four. Since the pressure on the ram faces is about 400 lb. per square inch, specially-designed pumps were required, and the electrical plant had to be designed to suit the conditions obtaining. The pumps are differential, with two 6 in. and two 4 in. rams. When doing full duty the pumps run at 25 revolutions per minute. It was found, by a preliminary trial of a smaller plant, that the load on the rams varied largely at different parts of the stroke. To avoid the heating that would be entailed in an ordinary motor working under a large current with a regular and rapid variation in its intensity, it was necessary to specially design the field and armature. Messrs. Immisch and Co. have successfully met the difficulty, and the plant has now been raising about 125,000 gallons per day for the last month. To give some idea of the electric problem, we may say that the current averages 66 amperes as read by a Siemens dynamometer; but varies at least 10 amperes on either side of the mean current. Mr. Blakesley has told us the heating effect of a varying current is not proportional to the square of the mean current, but it is equal to that plus half the square of the variable part. This is not all, however; the rapid variations of current increase largely the heating effects due to hysteresis and Foucault currents. The tension on the dynamo terminals is 600 volts, on the motor 575 volts. The actual horse power in the water, at the rate of 120 gallons per minute through 900 feet, is 33 h.p. nearly. The output of the dynamo is 53 h.p. Hence the efficiency between the actual useful work and the output of the dynamo is about 62 per cent. The commercial efficiency or ratio of useful work to belt power in dynamo cannot yet be stated accurately, owing to slip in the dynamo belt. However, taking the efficiency of conversion of the dynamo at the low estimate of 85 per cent., the commercial efficiency is not less than $\frac{62}{85} \times 100 =$ about 50 per cent.

This efficiency includes all the losses in transmission, viz. that in the dynamo, leads, motor, gearing, pumps, and rising main pipes. In this particular case about 2 1/2 h.p. is

not in the cables, and some 13 h.-p. is absorbed by the pumping and pumps, and by friction of the water in the pipes. It is contemplated shortly making a more complete test. Then indicator diagrams will be taken of the engines and pumps, and the various losses will be determined very exactly. But returning to our 50 per cent. conversion between the measured quantity of water and the brake engine power, could compressed air give such a return? The supporters of electricity would with much reason believe that compressed air would not give a return of more than 20 per cent. of the brake engine power. At any rate, it is curious that not one of the advocates of pneumatic transmission will publish a test of his plant. Mining engineers who have carefully measured the water delivered, and indicated their engines, give the result as varying from 15 per cent. to 25 per cent., and this latter under most favourable circumstances. Several gentlemen have recently written in the columns of the technical press advocating compressed air, and doubting the practicability of electricity. Surely now is their time to vindicate their position by figures and hard facts. In comparing the two systems, one must bear in mind that the losses in the steam engine, pumps and raising main are common, and can therefore be neglected as having no vital bearing on the real question. What we have to compare is the loss in dynamo, cables and motor, and that in compressors, supply pipes, accumulators, and air engines. The loss in the cable and supply pipes may also be struck out as quantities varying in every case, they affect more the capital outlay. Now a good dynamo and motor have a joint conversion efficiency of not less than 75 per cent., and under favourable circumstances may rise as high as 82 per cent. or even 84 per cent. But what will the most sanguine say about the compressors and air engines? Will they claim 50 per cent. and give the figures, as electrical engineers do? Probably, under very favourable circumstances, with low pressures, 50 per cent. might be reached, but with high pressure (such as would be required for 7,000 gallons per hour through 900ft., without an extravagantly large plant), the efficiency would be probably not more than 25 per cent.

Another important point of comparison lies in the prime cost of the plant. Omitting again the factors common to both systems, we have first a leading and return cable to set off against the pressure pipes. In most cases, the cables will cost both less than the pipes, and will be cheaper to erect. A double cable to transmit 50 h.-p. was run by Messrs. Immisch and Co. down a shaft of 300 yards deep in 7 hours. The dynamo and motor will be found also to cost less than the compressors, accumulators, and air engine to do the same work.

The question of prime cost is an important one; but, perhaps that of maintenance and security of running is more important still, in cases where breakdowns may entail very serious consequences. With electricity the cost of maintenance, judging from a large and varied experience of its application to nearly all kinds of machinery, is practically limited to the wear of brushes, commutators, and bearings.

A well made commutator also gives little or no trouble, and if kept clean will last a considerable time. The bearings will last for a long time, owing to the even strain put upon them. Of course, electrical plant requires to be properly designed for its work, and to be well laid down. But the majority of accidents that are likely to happen to such plant can be readily and quickly repaired and compare very favourably with the ugly breakdowns that occur with machines containing reciprocating parts. Indeed, if a proper method of management and daily testing of the system be made, a really serious breakdown is a very unlikely thing, for a fault is easily detected and made good before damage is done. No one, who has had experience of the two systems, will fail to endorse this. With compressed air plant there is not so much a risk of a bad breakdown, as a continual fiddling up of the brasses, crank pins, cotters, valves, valve seats, glands, &c. The number of wearing parts is so numerous and the strains so various that it is not to be wondered that the cost of maintenance is comparatively heavy.

It may be mentioned that the motor weighs about 3½ tons, and the dynamo nearly 1 ton. The machines are much heavier than the ordinary Immisch type for traction

purposes, in which every 70lb. of dead weight gives approximately a brake horse-power. But here weight did not enter into the question so much as slow speed and cool running. The machines are working well within the limits of their design, and are capable of doing 50 per cent. more work if necessary. The armatures, 24in. in diameter and 16in. long, are of the cylinder type, with massive commutators and substantial brushes and holders. The motor is wound according to Immisch's patent, and to this is mainly attributed the fact that they run practically sparkless, with a constant lead, although the load is varying 30 per cent. during every revolution of the pump. The speed of both dynamo and motor is 450 revolutions per minute.

The engine is a compound semi-fixed by Messrs. Robey & Co., of Lincoln, and works at a boiler pressure of 140 pounds per square inch. It is a 30 h.-p. nominal. The engine is similar to the one illustrated in our issue of March 2, but the smaller illustration (for which we are indebted to Messrs. Robey & Co.) given below will show the type of engine to those who may not have seen the number referred to.

Further particulars will be given when the full test is published. That the plant is a success may be judged from the fact that Messrs. Locke and Co. have given an order for two new machines of the same power. This new plant will be used to work an endless rope on an engine plane by day, and will be ready for pumping at night if required. This electrical plant is by far the largest at present running at a coal mine. It is confidently expected, however, that it will not long remain singular in this respect.

Insulating Cement.—According to the *Moniteur Industriel*, the Director of the Vesuvius observatory possesses an electrometer which is supposed to be the most perfect instrument of its kind. It was in reference to this instrument that M. Mascart observed, at the Meteorological Congress held in Rome—"So perfect is it that it might serve to control the indications of all other instruments of the same class in the world." This superiority is said to be due to the material with which the insulation is effected, viz., a cement formed of pitch from Greece (*poix grecque*), two parts; and calcined plaster, one part. The plaster in question, termed in Italian *scagliola*, is pure gypsum, which has been raised to a high temperature and thus deprived of half its water of constitution. It is a superior kind of plaster of paris, and, when mixed with water, hardens after combining with the proportion of this fluid which had been expelled by heat. The cement formed by admixture of the pitch with this plaster (presumably in the semi-dehydrated condition) is, when hot, a homogeneous viscid paste; it may be applied to apparatus by means of a brush, or it may be cast in moulds of any required form. It possesses the insulating properties of ebonite; but is softer and more plastic. A skilful manipulator can turn and polish it in the lathe. In colour it is slightly darker than amber. From the electrical point of view, its characteristic and useful property is that it retains its insulating power, whether it be exposed to a high temperature or to a moist atmosphere. We may add to the above that, at the period when Peltier's or Milner's electrometer was in common use for testing the insulation of cables, we obtained the most perfect insulation with a cement composed of shellac, gum dammar, and paraffin wax.

THE ELECTRICAL ENGINEER.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 6d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., who was in his scientific prime at the beginning of the century. This will be followed by SIR HUMPHREY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

AN EXPERIMENT.

The experiment of Mr. Bennett, the surveyor of Southampton, is one that should be kept well in view, for not only has it an influence upon the spread of electric lighting, but it makes electric energy, so to speak, a bye product. It may be well to recapitulate the experiment. A portion of the town refuse at Southampton is rendered innocuous by means of a destructor, which may be said to be a kiln especially designed for this purpose. Just as for many years the heat of smelting furnaces was wasted, so hitherto the heat generated by the destruction of refuse in these kilns has been lost. The idea suggested itself to Mr. Bennett of utilising the waste heat in generating steam, and the steam thus generated he used in driving a dynamo and producing the electric light. The general public, misled by the discussions upon the cost of the electric light, and usually not taking into account the whole data on the subject, hold strongly to the opinion that if they can only get natural power—wind or water—to drive the dynamos, the cost of the resultant light must be cheaper than the cost of gas. Of course all electrical engineers know that this result does not necessarily follow, nor must we be led into rash promises because we see the way to get the heat to generate the steam for nothing. While, however, we retain the right to examine every case upon its merits, generally speaking the utilisation of such waste heat will enable the electric light contractor to produce a result that should end in a large accession of business.

The possibilities arising out of this successful experiment are far beyond anything that can be understood by the ordinary electrical engineer whose business has led him very little among local authorities. Speaking with an experience which has brought us more or less into contact with every local authority in the United Kingdom, we can say unreservedly that one of the most difficult problems surveyors and engineers have attempted to solve, is that of getting rid of "town refuse." During the past few years great attention has been paid to the results obtained by these "destructors," and if they can be made to "kill two birds with one stone," we are convinced they will soon be reckoned by hundreds rather than as now by units. At present the destruction of the "refuse" is altogether a loss, which has to be borne by the rates; or, if that statement is going too far, we will say the return is so inappreciable that it is not taken into account. Mr. Bennett has shown a method by which a large part at least of the loss can be obviated. The construction of the "destructors" might with advantage be considerably altered, if they were erected with the double object of destroying the refuse and providing heat for the boilers.

The whole subject is of interest to the electrical engineer; but it is of far greater interest to the

orough engineer or surveyor. The first duty of the latter is to get rid of the refuse as cheaply as possible, and if he has decided that a destructor is the proper way to do this, he will most certainly get as large a return as he can for his expenditure. The figures attending such an experiment as that of Mr. Bennett must be taken as higher than would be the case in a properly designed installation. Probably, to drive one dynamo, only a fractional portion of the heat of the destructor is used. In an installation designed specially with a view to utilise this heat, the whole and not merely a part would be used. Small towns might, when the destructor could be conveniently placed, arrange for the whole of the lighting of the streets, if not for the lighting of the houses.

Unlike the case of an ordinary installation, where the cost of coal has to be carefully considered, the initial expense is the principal item under the conditions referred to. This opens up another vista to the local authorities as well as to the electrical engineer. The former will perhaps be ready to enter into a contract with the latter to supply a required number of heat units at so moderate a rate that the latter can safely enter into competition with rival illuminators. Suppose, for example, we take a destructor capable of giving heat to generate 1,000 h.-p., how would the obtaining of this heat at a moderate cost affect the maintenance of an installation of ten thousand lamps?

The coal consumed for such an installation would alone cost at, say, from 15s. to 20s. a ton, from £2,500 to £3,500 a year. The labour cost of putting this coal from the yard into the furnace would increase this item, and so far, if the proprietors of the destructor were using the heat themselves, the whole of this would be saved. On the other hand a purchaser in these early days of the suggestion, would probably get the "heat" at a very moderate cost. As time goes on and competition gets keener, the contractor would have to pay more. Further, many local authorities would be glad to pay a lump sum to a contractor to take the "destructor" work into his own hands, letting him do the best for himself that he could, so far as utilising the heat was concerned.

We have only glanced at this question, because just as one swallow does not make a summer, one experiment does not make a success. Further experiments will undoubtedly be made, when more can be said on the subject? Meanwhile we are strongly of the opinion that there is "money" in the idea, and that those firms whose tendencies are in the direction of town lighting, will do well to enquire closely as to the capability for using the heat of these destructors, and also where they are in existence or likely to be erected. The latter case presents the best opportunity for business.

CATALOGUE PIRACY.

A letter in another column directs attention to a practice that is becoming much too common. It is easy, as our correspondent says, to make up a respectable catalogue by taking information indiscriminately from various sources without acknowledgment. It is probable that the information so taken has been obtained at considerable expense in the original, and the pirate escapes all this trouble and expense. It is difficult, if not impossible, to prevent one firm following the arrangement of another firm; but even this has frequently been obtained at considerable cost, the first drafts having been altered and corrected till the appearance meets the approval of the principal. The Society of Telegraph-Engineers is, we fear, hardly the authority to adjudicate upon what, after all, are almost entirely trade questions; and, therefore, it does seem probable that sooner or later some other organisation must be provided to veto such practices. Our contemporary, *Electrical Plant*, suggests that a branch of the London Chamber of Commerce should take up questions affecting the welfare of the industry; but, again, it is doubtful whether the result would be that hoped for. The millennium is long in coming, and till then there will be business men who, in order to obtain some of the crumbs that fall to the share of well organised, successful firms, will follow as closely as possible the lines pursued by the successful ones. Sometimes the method of procedure leads to the law courts, but generally the pirating firm gets off scot free. The ordinary customer unfortunately knows nothing of how a catalogue is compiled, and believes when he receives one that it is the outcome of the purse and the brains of the firm which forwards it to him, and there is no means of dispelling this idea.

PITTSBURGH CONVENTION.

For the past week or two we have devoted a large amount of our space in reporting the various papers read at the recent American Conference of Electric Light Engineers at Pittsburgh. We have done this because, as might indeed have been expected, similar topics interest English electrical engineers, which also interest our brothers across the Atlantic; thus we have endeavoured to give a fair idea of the papers read as quickly as possible after the meeting. It will be seen from the reading of these papers that they almost wholly consist of the discussion of questions directly connected with practical work, and to a very little extent do they deal with anything purely theoretical.

CORRESPONDENCE.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR: We, in common with the author of the letter on the above subject in your last issue, feel exceedingly

alarmed at the prospect that opens out before us now that another set of rules have been published.

It would be difficult to arrange, at the present stage of the industry, any set of rules the following out of which could better guard against dangers arising from electric lighting than those which have been drawn up by Mr. Musgrave Heaphey.

The writer has seen a number of installations, both on the Continent and in the United States, with the result of feeling assured that work of this kind in England is infinitely superior to that carried out in other countries, and there can be no doubt that our comparative immunity from fire arises from the judicious enforcement of these.

A number of installations in this kingdom, including one or two of the largest, have been carried out by us, always under the Phoenix Fire Office Rules, and in no single instance has an electrical fire occurred.

It must certainly be the experience of every contractor that there is no difficulty in obtaining the approbation of the authorities for installations conscientiously executed.

If we are to have several sets of rules, it will be impossible to tender for work without a specification, and this means an expensive item added to the price of electrical work for the services of a consulting electrical engineer in each case, whose presence is unnecessary when a duly qualified fire inspector fills the position, free of cost, to the proposed user of the electric light.

We do think that this is a matter for the leading contracting firms to interest themselves in, and their verdict goes almost without saying.

To frame and impose rules, it is necessary to have a "status"—what is the "status" of those who are seeking to introduce the new ones, and what authority have they to handle a matter which so seriously affects the trade without first consulting it?

The matter is such a serious one that we trust more direct and public impeachment will quickly ensue. — Yours, &c.,

London, March 22, 1888.

INSTALLERS.

CATALOGUE PIRACY.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

Sir: As a further contribution to what has already been written on this subject, we would point out that the "catalogue of cables, leads, and insulated wires," issued this month by the Telegraph Manufacturing Company (Limited), of Helsby, contains exact copies of our price-lists of April, 1887, the only variation being different pattern numbers, and the omission of our name. Those interested in the subject might compare pages 10, 11, 12, 13, 14, and 15, with our April (1887) price lists. Not only are our figures copied *exactly*, but our phraseology, simply *servatum et litteratim*. Probably other parts of the catalogue have been made up by equally flagrant copies from other makers' lists, if we may judge from pages 30 and 31, where Cheeseman's table and formulae are given without acknowledgment.

Surely our Society of Telegraph-Engineers and Electricians might extend its sphere of usefulness by adjudicating on questions of privilege, and consider whether persons guilty of questionable practices are entitled to remain on their roll of members. Yours, &c.,

WALTER T. GLOVER AND CO.

Salford Electric Wirework, Manchester,
March 26th, 1888.

THE EQUITABLE TELEPHONE ASSOCIATION LIMITED.

[We have been requested to print the following notice. ED. E. E.]

The United Telephone Company having commenced proceedings for infringement, which they are advertising in the public press, against the Equitable Telephone Company, and having obtained against the latter Association an interim injunction, which they are also advertising, pending the trial of the action, which trial cannot come on for some months, the Equitable Telephone Association think it right to justify the conduct of their past business.

The Association was incorporated as long ago as the 15th

December, 1886, and although advised by eminent counsel that the instruments intended to be used by the Association were not infringements of the patents held by the United Telephone Company, yet the directors of the Association thought it right, having been informed of the pretensions of the United Telephone Company to a monopoly of the telephone business of the country, before commencing to supply instruments, to challenge the United Company to attack such instruments, with the hope and intention that the challenge would be accepted, and the litigation, which was then considered inevitable, terminated before the Association commenced to supply telephones to the public.

With this view the following letter was addressed by the solicitors of the Association in February, 1887, to the United Company, giving express notice of the intention to manufacture and sell telephonic apparatus under Mr Swinton's patent, and challenging the United Company to attack, if they dared do so, the instruments proposed to be manufactured and sold:—

"10 and 12, Queen Victoria street, E.C.,

"February 25, 1887

"Dear Sir,—We are instructed by the Equitable Telephone Association, Limited, to inform you that the Association is about to manufacture and sell telephonic apparatus, the transmitter of which is constructed under the various patents of Mr. A. A. Campbell Swinton, whose patent rights the Company has purchased.

"In order to give you an opportunity of inspecting the instruments, a set has been fitted up at these offices, and we are prepared to arrange an appointment to produce them for the inspection of yourself and your Company electricians.

"We should add that the Company is advised by eminent counsel that the instruments are in no way infringement of the patents held by your Company, but knowing the extent of the claims made by your Company, ill founded claims we believe, to altogether prevent the use of any electric transmitters in which carbon is used, the board of directors of our Company think it right to give your Company distinct notice of the intentions of the Association with the view to challenging your Company to contest the right of our Company to manufacture, use, and sell the instruments in question, should your Company after inspection think fit so to do, a contest which our directors will enter into with the full assurance they will succeed in maintaining the instruments it is the object of the Association to deal with."

"Yours faithfully,

"DAVIDSON & MORRIS."

To this challenge the United Company did not respond, and until the 9th of the present month of March, when a writ was issued without any previous warning or notice by the United Company against the Association, no objection was made by the United Company to the business the Association was transacting. This writ was followed by a motion for injunction, which was heard on Friday, the 16th March, when an interim injunction was granted, restraining the Association in the usual terms from dealing with telephonic instruments, the United Company giving the usual undertaking to be answerable in damages caused to the Association.

Owing to the short time at their disposal the Association was practically precluded from producing any scientific evidence on the hearing of the above motion, and their defence therefore rested solely on the question of their having been undue delay on the part of the United Company.

The Association have every intention of contesting the action to the utmost of their ability, and they will press the case on as far as lies in their power, with a view to as early a trial as practicable.

They believe that they have a complete defence, and they have every confidence that they will be able to uphold the complete freedom of their instruments.

THE FOWLER-LANCASTER DYNAMO.

It will be recollected that a few weeks ago we described a private installation at the house of Mr. Fowler (of Messrs Fowler, Lancaster and Co.), and mentioned that the dynamo used was one built by that firm, driven by a Sp

petroleum engine. We herewith illustrate the dynamo which, as will be seen, is of the Kapp type, with armature gramine ring, having a core built up of best Swedish charcoal iron discs of No. 22 R.W.G., insulated from each other with double tissue paper. It is wound with 48 sections of four turns single layer of No. 11 R.W.G. wire, and has a resistance of .06 ohms. The field-magnet cores are of the

best Swedish iron forgings, 3in. x 8½in. wound with No. 15 wire, having a resistance of 18 ohms. The output at a thousand revolutions is 53 amperes, with a pressure of 62.9 volts. It will be seen from our illustration and from these few details, that the machine is constructed according to the most modern practice, and it has in this special installation a heavy fly-wheel in order to obtain as regular running as possible.

WHAT CONSTITUTES A GOOD CARBON POINT.*

BY G. W. PARKER.

From the standpoint of the manufacturer all well baked carbons that are straight, free from cracks and other similar defects, and made from pure material, are good carbons.

The electric light engineer will say that no carbon is good unless it will centre properly and give him a reasonably long life with a good light. He is not at all inquisitive as to the method of its manufacture, provided it gives such results.

But as the manufacturer can go no further than to correct any error in his mechanical processes, the value of the carbon afterwards depends upon the conditions of its use. Such carbons as are described in the first paragraph will with some currents be satisfactory, both as to light and life. In others, the light may be brilliant and the life too short, or there may be arcs too short or too long, flaming or other defects arising from the unsuitability of the carbon to the current, there being no inherent defect in the pencil itself. Therefore, to cover the whole ground of this important inquiry, we should also have the carefully compiled statements of your experience of the behavior of carbons burning in your lamps under varying circumstances. From this results of great value to both sides might be obtained.

There appears to be no trouble in determining what constitutes a good carbon mechanically, but to you a good carbon means one that will give you satisfactory results in your use of it, and there we find several difficulties, without taking into account imperfections in your apparatus. The first is the difference in the strength of the currents used in the different systems, and also, in many cases, in different plants of the same system, the corresponding

differences in the resistance of each lamp, and, frequently, unequal adjustments of lamps in the same plant.

For convenience we are in the habit of referring to those systems in which a small current and a long arc is used as high tension systems, and those in which a large current and a short arc is used, as low tension systems. The requirements of the low tension seems to be a carbon that is hard, well plated, and a good conductor, the latter being the most important. In the high tension, on the contrary, hardness and conductivity seem to be of secondary importance. There is a tendency to flame and burn unsteadily when a hard carbon is used in these systems, and a softer one sometimes becomes necessary, which in many cases shortens the time in which the lamp will burn without being re-trimmed, but in such cases the difference is fully made up in the brilliancy of the light. On the other hand, where a soft carbon is burned in a low tension current, the tendency is to form needle points which prevent the carbon from centring properly, causes them to heat and is apt to burn the holder.

Let us pursue the inquiry touching the questions of size, conductivity, mortality and light, and ascertain if definite relations can be established in regard to them that may result in guiding us in the selection of perfect carbons for use from a mass of mechanically good carbons.

Diameters.—It is a matter of great interest to know in what manner and to what extent the size of the carbon affects the result in a current of given strength, covering, of course, in the general question of conductivity, the all-important results of light and life.

Hardness or Conductivity. It is well known that a hard carbon offers less resistance to the current, or, in other words, has greater conductivity than a soft one; therefore, in carbons of the same length and diameter, made of the same material, by the same process, conductivity increases and diminishes respectively with their hardness and softness. In either hard or soft carbons, whatever conductivity they possess respectively will be increased or diminished as their diameters are diminished, the length being maintained. It would appear, therefore, that it is possible to make a softer carbon of larger diameter that will be the equivalent, in conductivity, of a harder carbon of smaller diameter.

Mortality of Carbons. Of carbons of the same hardness and length, but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same diameter and length, but differing in hardness, the harder will outlive the softer. Therefore, a carbon of larger diameter, which is soft, may be equivalent to a smaller carbon which is hard, as to life, just as it has been shown to be equivalent in conductivity. The life of a carbon is, of course, dependent upon many vicissitudes, such as high winds, broken globes, &c., but under the same conditions the statement made above is undoubtedly a fact.

Brilliancy of Light. It is well known and admitted that as between hard and soft carbons of the same diameter the latter will give a more brilliant light. It is just as well known that in case of hard carbons those of smaller diameter will, within certain limits, give a more brilliant light than those of a larger diameter. On the above statement of facts it may be regarded as settled then that with the same diameter, but differing in hardness, the hard carbon will possess greater conductivity and have a longer life, but with less brilliancy of light; while the softer carbon will have less conductivity and a shorter life, with a more brilliant light. And, further, that with uniform hardness, but differing in diameter, the larger diameter will have the greater conductivity and longer life, with a less brilliant light; while the smaller diameter will have less conductivity and a shorter life, with a more brilliant light.

The foregoing statements indicate invariably that with greater conductivity light diminishes and life increases; and, conversely, that with diminished conductivity the brilliancy of the light is increased and the life shortened. In corroboration of this it appears that a small hard carbon is, practically, the equivalent of a larger, soft carbon, their conductivity being also equivalent.

Heretofore it has been considered probable that the diameter, candle-power, resistance per lamp, conductivity of the carbon point, and strength of current are all inter-

* Paper read before the National Electric Light Convention at Pittsburgh.

dependent, and a change in any of them will affect all the others, requiring a counteracting change or adjustment in some of them, in order to restore the proper relations between them. This, if so, you can readily see is difficult to do, for part of the work is to be done by the manufacturer, and the remainder is under your control.

On the other hand, if the deduction can be properly made from the statements herein presented, that the resistance of the carbon point will determine its capability in respect to light and life in the different currents, the trouble is practically removed. It is not impossible, I think, to construct a machine that will, at no great increase of cost, assort the carbons into groups of uniform resistance or conductivity. Then, with constant currents, clean lamps, perfect connections and insulation, you will ascertain practically that carbons mechanically good will prove to be good, and uniformly so, in actual service.

Much more could be written upon this interesting question, but this paper is already too long. I have noted for your discussion some important points which I hope your experience will enable you to determine definitely if they are well taken or not. I would be glad to have the whole question of the imperfect burning of carbon points thoroughly canvassed, so that manufacturers would get some hints as to what may be done by them in the way of correction when the fault lies at their door. It is especially desirable to be informed if that very disagreeable feature in the burning of carbons called "flaming" is always the effect of one particular cause and what that cause is.

THE UNDERGROUNDING OF ELECTRIC ARC WIRES.*

BY W. W. LECGOTT.

This topic is one of absorbing interest at the present time. Municipal and legislative authority seeks to compel the burying of all the wires without discrimination, and to cast upon the parties interested the burden of finding a practical means to accomplish the end. The progress of invention in science and art records, infallibly, the contemporaneous public drama. This demand discloses a necessity, and inventive ingenuity suggests the remedy.

Starting from this standpoint we find public wiring began with the telegraph. In 1753 Marshall, of Paisley, evolved an electric telegraph wherein insulated wires were to be trained on poles, and so Lomond in 1787, Beton Court in the same year, Riezen in 1794, Cavallo in 1795, Salva in 1796, Summering in 1809, Cox in 1810, and Sharp in 1813 all had telegraphs employed, from one to twenty-six wires, trained on poles.

At this stage, however, the interesting experiment to which the world lent a helping hand developed signs of commercial utility and value. Man's cupidity and selfishness at once antagonises what he cannot share, and we find the public arrayed in opposition to the use of the highways. Inventive ingenuity came to the rescue, and in 1816 Ronalds erected and used a telegraph in which some of his wires were placed on poles, and *some were buried in the ground*. Trihauillet followed, in 1828, with a system employing underground wires; and when Prof. Morse, in 1832, brought out his system, he proposed connecting Washington with Baltimore, a distance of 44 miles. To his mind, the wires should be insulated in a tube laid in the ground. He constructed his line with great care, and at large expense, but only a few miles had been laid when the gradual escape from his line proved his scheme impracticable. He was about to abandon the undertaking, when one of his condjutors, Dr. Page, of the Patent Office, or Prof. Henry, of the Smithsonian Institute, said to him: "Take your wire from the ground, and train it on poles." The advice was followed and success achieved. Here, then, in the incipency of public wiring is the first recorded failure coupled with its remedy. Take the wires from the ground and put them on poles. With underground telegraph and telephone wires the electrical difficulties to overcome are much the same. Moisture must be excluded from the wires, insulation must

be good and induction be reduced to the minimum, especially between adjacent lines. In both, however, leakage from the lines due to imperfect insulation may be compensated within limits by additional battery force. The battery acts like a pump sending water through a leaky pipe; the water may all escape before reaching the discharge end, but with a more powerful pump, while increase of pressure will cause greater escape through leakage, one may succeed in discharging a limited quantity through the end of the pipe, and so accomplish the purpose sought. For this reason underground telegraph and telephone wires may be operated with a measure of success.

In most of our cities all telegraph wires might be led to a certain point from which the wires of all systems could by one underground conduit be led to a central station or stations, and thence back through the same conduit, and where the wires are numerous might warrant the expense. With telephone companies whose subscribers are in all parts of the city, the requirements that each wire should be conveyed underground would involve an outlay for conduits wholly prohibitive. For direct service incandescent lighting the required conductors are so large, that to train them upon poles, or to train an equivalent capacity in smaller wires on poles, would involve outlay and annoyance exceeding that required to underground the conductors. So, again, the resistance of the conductors to the flow of the current is exceedingly slight, it might be compared to the pouring of water from a pitcher through a six-inch pipe, its course of least resistance lies right forward through the pipe and there is little tendency to seek an exit through any other restricted channel. In comparison with it the arc light current might be likened to a large hose with a small nozzle, through which water is being forced with a powerful pump, the tension is very great, and if so much as a pin hole exists in the hose water will squirt therefrom and quickly enlarge the orifice to a fatal rent. From the fact, therefore, that telegraph and telephone and incandescent electric light wires may be trained underground with success, by no means does it follow that the same is true of arc light wires. It is an undoubted fact that to successfully underground electric arc light wires involves simply and solely a question of expense. But expense may be of the very essence of the inquiry, for if the expense is out of proportion to the revenue that can be derived from the service, expense alone prohibits the outlay and determines it to be impracticable. Expenditure of money is alone required to tunnel the Dover Straits, and yet French and English capitalists have pronounced it wholly impracticable, as the returns could not warrant the investment. So it is with electric arc light wires; an efficient system so far as inventive ingenuity has yet presented any plan involves an expenditure wholly prohibitive, and for that reason alone is impracticable. Electric arc light wires may be employed successfully, trained in the air on poles, and in underground system is practicable which can reproduce the same conditions. Let us examine these conditions. All substances are conductors, as copper, iron, lead, rubber, glass, dry air. Some substances are such poor conductors, that, in comparison with those that are better, we call them non-conductors, and the greatest available non conductor is dry air. We use these poor or non conductors, such as rubber, glass, paraffin, wood, and dry air as insulators, and we find dry air to be our most perfect insulator. Dry air is a better insulator than rubber, if, therefore, in dry air two rubber covered wires cross in close proximity to each other, the induction is greater between them than would be the case if both wires were bare. But air is usually laden with moisture, and water charged as it is with the mineral salts and acids of the atmosphere, is a good conductor. We therefore coat our line wires with an insulating material, to shield them from direct contact with moist surfaces or other good conductors, and so reduce in amount the current which is always escaping by connection to the ground, and which varies in direct proportion to the conducting property of the intermediate medium. Where insulated wires are trained on poles, we have, at the rate of 30 poles to the mile, thirty points at which a small amount of current may and always does slip off to the ground. Now let us put an insulated cable in a con-

* Paper read before the National Electric Light Convention at Pittsburgh.

Table I. shows the maximum loss expressed in volts, the corresponding maximum per cent. of loss, the corresponding average per cent. of loss, and, consequently, the average efficiency of the system of conductors —

TABLE I.

System.	Three wire System.			1,000 Volt Alternating Current System.		
Maximum loss in volts	12.5	20	30	25	5	100
Maximum loss in per cent.	10	15	20	2.5	5	10
Average loss in per cent.	4	6	8	1	2	4
Average efficiency	96	94	92	99	98	96

These two tables show the individual efficiency of the different portions of the two systems, and the total efficiency from the driving belt up to and including the portions named. I have granted in all cases for the converter system an efficiency of 98 per cent. for the primary and 99 per cent. for the secondary conductors. With a commercial efficiency of 90 per cent. for the generator and 95 per cent. for the converter, which is sometimes claimed for them by some, the total efficiency is 82.9 per cent. With a commercial efficiency of 85 per cent. for the generator and 90 per cent. for the converter, which is believed by others to be liberal, the total efficiency is 74.2 per cent. In the three wire system we have assumed an efficiency of the generator of 92 per cent., which result is obtained by every maker of a first class dynamo of this type, and an efficiency of 99 per cent. for both the mains and the inside wiring, both of which portions of the system are in practice calculated for a maximum loss of 2 per cent.

The maximum loss in the feeders in Table II. is made 10, 15, and 20 per cent., with a corresponding average loss of 4, 6, and 8 per cent., and an efficiency of 96, 94, and 92 per cent.

TABLE II — Alternating Current Converter System.

	Indiv.	Total.	Indiv.	Total.	Indiv.	Total.
Efficiency of generator	90	90	88	88	85	85
Efficiency of feeder	98	88.2	98	88.2	96	83.3
Efficiency of converter	95	83.8	92	79.3	90	76
Efficiency of services and inside wiring	99	82.9	99	79.5	99	74.2

Three-Wire System.

	Indiv.	Total.	Indiv.	Total.	Indiv.	Total.
Efficiency of generator	92	92	92	92	92	92
Efficiency of feeder	96	88.2	94	86.5	92	84.6
Efficiency of mains	99	87.3	99	85.6	99	83.7
Efficiency of services and inside wiring	99	86.5	99	84.7	99	82.9

Assuming the highest efficiency claimed for the alternating current generator, and assuming the generator is as efficient as a continuous current generator under conditions of partial load, which is not likely, and assuming that the converter has the same efficiency under partial load as under full load, which we know cannot be; we are still met with the fact that the three wire system, with a maximum loss of 20 per cent. in the feeders, has as high an efficiency as the converter system, allowing it every possible claim, and that the three-wire system, as usually installed, with a maximum of 10 per cent. loss in feeders, has a superior efficiency of from 4 to 12 per cent. over the alternating current converter system.

To return now to the question of first cost, assuming the cost of copper at 16 cents per lb., I have figured the cost of copper conductors for feeders for 16 c.-p., 50 watt lamps, for distances of 1,000, 2,000, 3,000, 4,000, 5,000, and 6,000 feet, with an average loss in conductors of 4, 6, and 8 per cent. for the three-wire system, and 2 per cent. for the alternating system, with 1,000 volts initial E.M.F., cost is expressed in dollars and decimal fractions thereof.

I have also calculated the cost of copper in the mains for one 16 c.-p. lamp on the basis of a distance of 800ft. between feeder terminals in the three-wire system, and a maximum loss of 2 per cent., and find it to be 13 cents. Also the cost of services and inside wiring, in the three-wire system, on basis of an average distance to lamps of 100ft., and 2 per cent. loss, and since the full benefit of the three wire distribution cannot be attained in the inside wiring, have assumed the saving of one-third over the two wire system, instead of the two thirds saving effected in cases where the full benefit can be attained. On this basis, the cost of copper for services and inside wiring is 6½ cents per lamp.

TABLE III.—Cost of Copper for Three-Wire Feeder per 16 c. p. Lamp (50 watts, 110 volts, Copper at 16 cents per lb.)

Distances	1,000	2,000	3,000	4,000	5,000	6,000
12.5 volts maximum loss equals 5 volts average loss, which is 4 per cent.	.266	1.064	2.394	4.256	6.65	9.576
20 volts maximum loss equals 8 volts average, which is 6 per cent.	.1615	.646	1.453	2.584	4.037	5.812
30 volts maximum loss equals 12 volts average, which is 8 per cent.	.1077	.430	.969	1.723	2.69	3.87

Cost of Primary and Secondary Circuits and Converters for 1,000 Volt Alternating Current Converter System, per 16 c. p. Lamp at average distances.

Distances	1,000	2,000	3,000	4,000	5,000	6,000
Primary	.0213	.085	.191	.340	.530	.764
Converter	3.000	3.000	3.000	3.000	3.000	3.000
Secondary	.240	.240	.240	.240	.240	.240
Total	3.2613	3.325	3.431	3.580	3.770	4.004

In the alternating current converter system I have assumed the cost of converters recently quoted by Mr. Stanley, the electrician of the Westinghouse Company, in a paper before the Boston Society of Arts. This figure is three dollars per lamp. I have calculated the cost of copper per 16 candle-power 50 volt and 50 watt lamp with an average distance to the lamp of but 75ft., and with 2 per cent. loss, and found the cost of copper to be 24 cents per lamp. With an average distance of 100ft., as assumed in the case of the three-wire system, the cost of conductors for the inside wiring would be 43 cents. In making the comparisons, however, we will give them the advantage due to the 75ft. distribution—that is, 24 cents per lamp.

I have plotted these results expressing cost as ordinates and distances as abscissae. The curves resulting are here shown. (See diagram.) In the diagram, curve No. 1 shows cost of primary converter and secondary for alternating system (converters at \$3 per lamp). No. 2 shows cost of primary and converter for alternating system. Number 3 shows cost of primary for alternating system. Number 4 shows cost of feeders for average loss of 4 per cent. Number 5 shows cost of feeders for average loss of 6 per cent. Number 6 shows cost of feeders for average loss of 8 per cent. Number 7 shows cost of feeders and mains for average loss of 9 per cent. Number 8 shows cost of feeders and mains in the three-wire system for average loss of 6 per cent. Number 9 shows cost of feeders and mains in the three-wire system for average loss of 8 per cent.

In the three-wire system curves for total cost are the lines in black just above the dotted lines. It will be seen that if the three wire system be operated at an average efficiency of 92 per cent. in the feeder, which corresponds to the highest efficiency claimed for the alternating current converter system, the total cost per lamp would be equal when the average length of feeder was 6,000ft. An average length of feeder of 6,000ft. corresponds to circular area 18,000ft. in diameter—that is, about 3½ miles in diameter. In practice, it is preferable to operate at higher efficiency, making a large investment in copper, which has the strong recommendation of having the least depreciation, and requiring the least attention of anything used in connection with the transmission of energy.

The middle curves represent an average efficiency of 94 per cent. in the feeder—that is, an average loss of 6 percent. in the feeder. You will notice that even with this superior efficiency the three wire system is cheaper per lamp than the alternating current converter system at an average length of feeder of 4,750ft., corresponding to circular area of 12,000ft. in diameter,

and that for shorter distances the cost rapidly diminishes—the cost of conductors for three-wire system at this efficiency with an average length of feeder of 3,000ft. corresponding to circular area of 9,000ft. in diameter, being less than one-half the cost of conductors and converters for the alternating system.

Even with the very high efficiency of 96 per cent. in the feeder, or an average loss of but 4 per cent. the conductors of the three-wire system are cheaper than the conductors and converters of the alternating current converter system for an average length of feeder of 3,600 feet or less, and this corresponds to a circular area of 11,000ft. in diameter.

Suppose that both the generator and converter are so much cheaper than we have assumed as above that it makes a total reduction of one dollar per lamp. We then find that under conditions of equal efficiency, 82.9 per cent., the three-wire is cheaper where the average distance to lamps is one mile or less. With the usual efficiency for the three-wire system, 84.7 per cent., it is the cheaper for an average distance to lamps of 4,000 feet or less, and with the highest efficiency, that is 86.5 per cent., with average loss of 4 per cent. in the feeders, the three-wire system would be the cheaper when the average distance to lamps is 3,000 feet or less.

Suppose, on the other hand, that the incandescent lamp be dimmed in voltage and increased 25 per cent. in economy; at the same time that the cost of converter was reduced to two-thirds its present cost, and we find that with the highest efficiency, 96 per cent. in the feeders, the three-wire system would be the cheaper for cases where average distance to lamps is 8,000 feet or less, which corresponds to a circular district about five miles across.

Before leaving the question of economy of operation let us look at the question of depreciation. In any dynamo the depreciation naturally becomes greater when it is operated at high E.M.F., even where the type is the same, and in the high E.M.F. alternating current generator there exists the greatest tendency toward troubles due to the breaking down of the insulation of the wire on the armature. The secondary circuit of the alternating current system and the inside wiring of the three-wire system would have a similar depreciation, but there is a great difference between the depreciation of copper conductors carrying low E.M.F. continuous currents and the depreciation of highly insulated conductors carrying a high E.M.F. alternating current together with the depreciation on an expensive piece of apparatus like the converter, the large proportion of the cost of which is represented by labour. Try to compare the value of copper 20 years hence which costs \$1,000 to-day with \$1,000 of converters, and small highly insulated wire such as used in the primary circuit of the alternating system, and I think it will be evident that the depreciation of the alternating system is going to be many times that of the three-wire system.

Reliability.—In ordinary practice in the three-wire system every lamp is partially supplied by every feeder on that side of the system. That is, the current can flow out on any such feeder and through the network of mains, and finally reach the individual lamp. Similarly, every lamp is supplied in part by every dynamo operating in multiple on that side of the system, so that the larger the system, the more reliable it becomes; and an accident to an individual main, feeder, dynamo belt, or engine, does not in any way affect the operation of the light, and in the worst event trouble in an individual building would result in half the lamps on that circuit going out, and the other half would be scattered alternately among those which would go out, so that the result would not be even trouble some.

Now how about the alternating system? Thus far they have not found it practicable to operate their generators in multiple and it is not likely that they will ever be able to in common practice. This means more than is generally appreciated. Every lamp burning on an alternating system depends upon the continuous operation in unison of six separate appliances, each of which is liable at any moment to cause an instantaneous extinction of the light in question. These six things are—

- First. The individual secondary circuit which supplies the lamp.
- Second. The individual converter which supplies the lamp.
- Third. The individual primary circuit which supplies the converter.
- Fourth. The individual generator which supplies the converter.
- Fifth. The individual belt for the generator.
- Sixth. The individual engine which supplies the power.

The next best thing to reliability is ability to reduce the time brought in out to a minimum, and to accomplish this it becomes necessary to install a spare system of conductors which are only brought into service when a primary circuit gets into trouble. An expensive switchboard in the central station also becomes necessary, so that in case of trouble to a generator its load can be thrown over to another generator with the least possible interruption of the lights that the generator has been supplying. The secondary circuits from one primary can be multiplexed, and this is sometimes done, and this adds somewhat to the reliability of the light, but the expense due to this connecting of converters by heavy wires required by 50-volt lamps makes it impracticable in usual instances.

Unless the alternating current generators are operated in

multiple are the reliability of the alternating system cannot be as good as that of an arc light system, and we all know how reliable that is.

Variety and Value of the Possible Sources of Revenue.—We now come to the consideration of the variety and value of the possible sources of revenue. The first and most important revenue for a central lighting station outside of the light itself is power.

In a central station running night and day the cost of generating additional power beyond that required for the light is quite small, probably not exceeding 30 cts. per horse power per year for ten hours per day. This amount of power distributed in small units as required in practice will readily sell for 100 cts. per year. Owing to the fact that a large number of small motors, varying in their requirements as to power from moment to moment are supplied from one common source, a certain production of horse power will supply the demands of motors representing a total maximum horse-power somewhat one and one-half times as much as is produced. In other words, for every horse-power produced at 30 cts. you can sell two and one-half at 100 cts. each; or you can sell for 250 cts. what it has cost you 30 cts. to produce. It goes without saying that the ability to supply such demands is of the utmost importance to a central station. The continuous-current system is well adapted to the supply of power for any and all purposes. No practical method of operating a motor by means of the alternating current has as yet been devised, and the problem presents great difficulties, principally on account of the necessity of a comparatively continuous current for charging the fields and the instability of the torque of such a motor.

We are promised great results and extended use of the storage battery, and undoubtedly it will be used considerably for a great many purposes, therefore there is a large possible revenue from this source, which the alternating system will not be able to supply.

Then there is almost unlimited number of applications of a continuous current on a small scale for such purposes as fire alarms, burglar alarms, distribution of time, annunciators, tickers, electroplating, telegraph lines and telephones, all of which rely upon a continuous current, and there are innumerable applications which will soon develop consequent upon the absolute reliability and constancy of the electrical pressure at command. Out of the numberless applications of the electric current which we see daily, I can think of no commercial application except the production of light and heat, for which the alternating current under discussion is available, and the production of heat by the electric current does not present a flattering outlook as a source of revenue to the owners of central station plants. Therefore, we see that to-day the alternating system is dependent for its revenue upon the sale of light alone, while the continuous current is applicable to almost every conceivable use to which the electric current is put.

Safety to Life.—The safety to life of the three-wire continuous current system using about 280 volts as a maximum E.M.F. is undoubtedly absolute. It is impossible for a consumer of such a system to injure himself by the shock in any conceivable way, and a slight burn in case he makes a short circuit in too close proximity to some portion of his person is the worst result possible, and this is almost an unheard of possibility. It has been conclusively proven in practice that the 1,000 volt alternating current is fatal to human life, and will kill a horse. Although perhaps not likely to occur, it is always possible for the primary and secondary to get into contact, either in the converter itself, or possibly in circuits outside of it. Any person handling the wires of the secondary, and a fairly good ground, is then liable, through a possible ground elsewhere, to be instantaneously killed. The most dangerous thing is the one which is usually perfectly safe, and occasionally dangerous; as is witnessed by the death of a telephone operator at Pittsburgh recently. While he was, as usual, handling various contacts about the switchboard, a high electromotive force circuit became closed somewhere outside with the telephone line, and without the slightest suspicion of any possible danger he was instantly killed in doing what he had done thousands of times before.

Effect Upon Existing Property.—The low E.M.F. of the ordinary three-wire system, the perfect protection from excessive current effected by the safety devices in use and the continuous character of its current, render it practically inert as far as its influence upon existing property is concerned. That the alternating system, with its high E.M.F. and its strong inductive influence, will occasionally cause serious trouble to existing telegraph, telephone, and other lines which it is adjacent to, seems inevitable.

From the foregoing comparisons, I consider the alternating current is not applicable to central station lighting, as it is at present operated, except as a possible adjunct, or else upon an extremely small scale in cases where a few lights very greatly scattered are required, and where power is cheap. In cases where cheap power exists at a distance of several miles from a town capable of supporting a station of 2,000 lamps and upwards, high initial E.M.F. becomes both desirable and necessary, but the continuous current converter, which already exists in several forms, and which is receiving the attention of the best

electricians and inventors of the world, will, in my opinion, be the device to supply this demand, and that very shortly.—*Western Electrician.*

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

DISCUSSION ON MESSRS. KAPP AND MACKENZIE'S PAPERS ON "TRANSFORMERS."

(Continued from page 302.)

Mr. Esson said: In dealing with this problem Mr. Kapp had introduced the graphic method, which was always a great boon to the engineer. Throughout his investigations, however, Mr. Kapp assumed that the electromotive force impressed in the primary, or rather the electromotive force generated by the dynamo, was a sine function of the time. But surely in modern machines, with iron cores in their armatures, that was not quite the case. He could believe that in a Siemens dynamo the curve would be a sine function, and also in a Ferranti dynamo the deviation might not be great, but in a dynamo having an iron core in its armature, he could say most decidedly it would not be a sine function, nor would it be anything approximating to a sine function. He had endeavoured to map out the magnetic field in a dynamo something like Mr. Kapp's own design, where they had a disc armature with sets of poles on each side. The result was shown by a diagram, where the curve of sines was shown, and the curve got from the dynamo in the latter. They would see the flat part in the middle. That part might be a little too long in the diagram, but its length depended entirely on the construction and the proportions. The point regarding the degree to which the core of the transformers could be saturated was most interesting. From Mr. Kapp's investigations it seemed that the number of C.G.S. lines was only one-half of what could be employed in the armature of the continuous current dynamo. He would like to know the usual weight of transformer per 60 watt lamp, and also how many volts he got per foot of conductor. In the Westinghouse transformer, he believed, they got 2 volts per foot. There seemed to be very little difference in the construction of the transformers, excepting that the object in some cases appeared to be variation rather than an improvement. He thought the transformer of Mr. Kapp had an advantage over others, inasmuch as it could be taken to pieces. Leaving transformers and coming to the distribution, it seemed that here there was some little room for discussion. He understood Mr. Bernstein to advocate the series system, and in his paper Mr. Mackenzie showed himself rather favourably disposed towards it. It appeared that putting a constant current in the primary they had a current which was practically constant in the secondary, and therefore the arrangement was admirably adapted for lighting lamps in series. So far, then, as self-regulation went, there was no difference between the two systems, but when they came to the question of cost he thought that the conductors would cost more, in any case, in the series system than it would in the parallel system. They had to keep the same section of conductor right through the system. If they had to go down 100 yards to light a single lamp, they would still carry a heavy conductor with them wherever they went, and although Mr. Kapp said that in sparsely populated districts the cost would be less, he himself could not quite make out how it was. In conclusion, he had been very much puzzled by the last sentence in Mr. Kapp's paper. He was not quite sure whether it was intended to be prophetic or not. If Mr. Kapp thought that they really would get batteries sufficiently improved to render lighting by continuous currents possible in the future, it would be a great pity, though having the conductors all right, to find at the generating station dynamo of the wrong kind, and the transformers also useless. He therefore advised Mr. Kapp to give up the alternate-current system, to put in at the generating station high-tension dynamo, and to use continuous current transformers at the sub-stations. He would then be ready, on the contingency of a good battery arising, to supply by storage. He could either charge his accumulators direct from the central station, he could charge them through his transformers, or work the lamps from the transformers. He (the speaker) did not say that the system of working with a continuous current transformer would be quite of such high efficiency as the alternating transformer system. Neither would it be so low as working from accumulators, as Mr. Crompton advised, but it would be somewhere between the two, and the accumulators would be simply used as a stand-by. They would be charged occasionally, just to make up the leakage.

Mr. Sidney Evershed also referred to the sine function. Mr. Esson had been good enough to give the meeting a diagram of one curve, which showed what a complicated function a modern dynamo might give. The Westinghouse dynamo was also supposed to give not a sine curve but something like a zigzag of straight lines. The only way he could see of attacking that problem was to assume that it was a hyperbolic function; but he could only echo Mr. Kapp's wish, that some one with the necessary mathematical attainments would investigate the subject. Dr. Fleming described a large wattmeter, which apparently gave very inaccurate results. There was really no need for a wattmeter to be large. If Dr. Fleming were to make a wattmeter like those beautiful instruments which he showed at the meeting last year, and employ a few amperes turns—say, two or three on the pressure coil, and a large number, 100 or so, on the current coil, they would have an instrument in which there was practically no lag in the pressure coil, and consequently it would give the mean of the instantaneous watts.

Prof. Perry said he should like to say a word or two upon this matter of the sine curve. It had been said by Mr. Esson and by Mr.

Evershed that the curve was not a true sine curve, and therefore that Mr. Kapp's theory must be wrong. Before, in that room, he had made a correction of such statements. He understood that Mr. Esson measured his field, the field of the dynamo machine, to get this particular curve. If they got Mr. Esson's curve for the field, then the current—the primary current—would obey very nearly the sine law, and the law of the secondary from the transformer got nearer to a sine function still. The effect of self induction and mutual induction was that they took out the minor ripples. A curve like that of Mr. Esson's was built up in this way, of several sine curves of different periods. A combination of one sine curve and its harmonics would give the curious curve that Mr. Esson described. They found that if they had one sine function of a certain period, another of twice that period, and others three times that period, they could get exactly what the effect of self induction was in tuning down the ripples of the harmonics. It depended on the self induction. All these ripples were tuned down, and the quicker ripples tuned down very much more rapidly than the slower ripples in passing through the transformer, and he did not think it was possible by any method of measurement to get anything very different from a true sine curve in the secondary current. Mr. Esson, Mr. Evershed and others had said that there was not a true sine curve. Well, then, there was a way of testing it and the way of testing it would be this. Let them take a dynamometer, and send the alternating current through the thick wire coil only. Then let them take the fine wire coil, and have a little battery with a make and break, and let that make and break be controlled in some way so that they could readily vary the rate of vibration—the rate of vibration, say, of some tuning fork. Let it be varied, so that they could measure the rate of the make and break. The main current might have any amount of ripples in it that they liked to assume. Now when the rate of alternation in the fine wire coil reached the fundamental rate of alternation in the coarse coil, and then only, they would have attraction between one coil and the other. If the main current had no other rate of alternation than that, according to Fourier's theorem they would have no action of it one coil on the other, except at that one rate of vibration. So that by changing gradually their make and break—changing it to quick from slow—they looked out for an indication. And when their readings on this instrument were greatest, when they knew they had got the alternation of the main wave—the main alternation of the current—they had got their main wave then, but they had not got any of the ripples. They now continued to quicken their make and break, made it quicker and quicker, and when they got to twice the rate of vibration they would probably see some indication. If it was small it meant a small ripple of twice the ordinary alternation rate. Well, let them measure what it was, then go quicker and quicker till they got about three times the first speed. They would probably get another indication. Probably there was some period which had a pretty big effect. If he was right, however, in what he had been saying about the tuning down of the ripples, they would not get much indication at any other speed than the one speed which indicated the main wave. It was easy to take the results and combine the measured fundamental wave with its measured harmonics, to find the real shape of the current function. It would be known to members that if the coils were at right angles to one another mutual induction would vanish and no error could arise from this cause.

Mr. Morley thought there was no doubt whatever, from what had been seen on the other side of the Atlantic, that transformers had a great future before them. Mr. Crompton said that the bottom would be knocked out of his argument if it could be shown that small alternating current dynamos could be used, and could be put in parallel. It was easy to knock the bottom out of the argument. In the United States machines were being run in parallel not only in one large station, but it had been done across rivers. A station on one side of a river is supplying mains connected with a network on the other side, as well as on its own side; and when it is necessary to put more power on the mains, the dynamos on the other side of the river are switched in. He did not think there was any serious difficulty. There was one objection he would like to make to the conclusion of Mr. Kapp's paper, and that was as to the use of low-tension networks with transformers. It seemed to him that the great advantage they had in transformers was that they got rid of the enormous cost of a low tension network. Everybody had known that the cost of the copper in a low-tension distribution system had been a very serious item on the whole. It seemed to him that as transformers regulated so perfectly, and as they could be made to regulate even more perfectly than they did just in their simple state, and as they were undoubtedly very efficient indeed for small loads, and further, as loss in the main conductors could be at a practically small cost rendered of no practical effect whatever, it seemed to him that they got rid entirely of any necessity for the distribution network. They only wanted a distribution network that would help one part from another when the wires of any one part were not sufficient to carry a full current. He disagreed as to the danger of having separate transformers for every house. It might not be necessary to put them in every house, but he certainly thought that if some simple arrangement were made for cutting out a transformer when anything went wrong with it, it was the very best thing they could do. They might put a number of transformers right along the mains, and just one house would be cut out, and no more, when the transformer in that house went wrong. He even went so far as this, that in a big house like a hotel he would run the mains to the outside of the buildings, he would take the wires in at two or three places from the outside, and put transformers at those points. To that extent, perhaps, a network system might be used—that is, with the inexpensive primary rather than the expensive secondary conductors. With regard to the employment of series or of parallel systems of connection he thought the advocates of the series connection of transformers forgot two difficulties. One was that the regulations of the constant current system with an alternating current dynamo was not at all easy. He did not know that that had been done yet. They could

they were doing full work. It was clear that for all purposes of distribution transformers were the order of the day, whether by alternate currents on the one hand, or by accumulators, or in the third case by motor dynamos. It was clear that they had to study the question of transformation in all its bearings for the basis of immediate distribution.

Mr. Kent said, there are three distinct ways of obtaining self-regulation when the primary coils of the transformers are in series.

- 1st. By putting all the lamps in series on Mr. Bernstein's system.
- 2nd. By the use of what have been called our "choking" coils, or what we prefer to call "impedance" coils.
- 3rd. By building up the transformer in sections so far as the core of the secondary is concerned, and connecting each lamp or group of lamps to its separate section.

The first and third of these methods is admirable for small or medium-sized transformers, and the third will do for any size. All three are perfectly self-regulating.

Mr. Kapp, in reply, said that in the first place he would answer Prof. Silvanus Thompson as to the difference between the core transformer and the shell transformer. The shell transformer had one set of coils and two cores or more. A core transformer had one core and two sets of coils or more. Now, as to Mr. Wright's contention that the shell transformer was superior. He quite agreed with that gentleman, and that was the reason why he made a shell transformer. He did not say the Ziperowski was superior, he said it was inferior. It was a shell transformer of a circular ring type. It might interest Mr. Wright to know that what he arrived at through cautious Ziperowski had found out by experiment. He had abandoned the Ziperowski type of transformer, and now made ordinary Gramme rings. Mr. Morley suggested a very interesting experiment. The angle of lag in one or two of his Mr. Kapp's diagrams was so small that the cosines had such values as 999; so that they might imagine they could not get an appreciable difference in the readings. Probably there was a difference, but the error of the measuring instrument was greater than the difference. As to the cost of the network, he objected to putting transformers into houses singly on the ground of safety, and he thought whatever they did that they must study the safety of their customers before the coal bill and before any other consideration. If they adopted the principle of distributing the secondary currents by means of a proper network, once they had laid it down, they could see it when that happy time arrived when they could employ the battery system. He would now deal with Mr. Gordon and Mr. Crompton. When he heard those two gentlemen speak he began to feel very doubtful whether, after all, they were not all of them going on a wrong line, but then he was comforted with the idea that supposing even such a man as Edison, or Brush, or Westinghouse had been present, and had seen Mr. Gordon's diagram, he would have gone home disheartened, and resolved never to put up a central station again because of the enormous consumption of current when the people had gone to dress for dinner. But what was the fact? How many battery stations were there in the world? He knew of absolutely only one in London, one in Berlin, and one in Vienna. How many central stations on other systems were at work he was afraid to say, but he thought in America there was something like 1,000. On the Continent of Europe there were perhaps 100 or 150. In England there were perhaps fifteen. All these were working on the direct system, and their machinery must be capable of supplying the extra current shown on the diagram. But that was a bad case. In reality they could only have that effect when they lighted the same class of houses throughout a district; but in London they never had a district so defined. They had residential mansions, and within a stone's throw they had news and shops, all within the area which would be supplied from one station. That being the case, they would never have to meet such a state of things as Mr. Gordon suggested. If they had to meet it all they would have to do would be to make some allowance in their machinery. In what way was Mr. Crompton better off than they were? He had to supply this extra amount of light from the batteries instead of from the machines. They would have to put up more cells, and it was the battery which cost the money, not the engines. He was not against batteries in any way. He would had the day when they could get a good battery, but all the arguments used by Mr. Crompton and Mr. Gordon might have been used with equal consistency three years ago. They had batteries then, and they had very good direct-current steam engines and dynamos. Had they good enough batteries now? He had not seen them. The batteries which were at the Colonial Exhibition gave an efficiency of under 60 per cent. They were in the hands of experts. Everything was done that could be done. They were under supervision all day long, and yet there was only 60 per cent. efficiency. When it was said that transformers were bad because they had a low efficiency when the output was very small, they must remember that they could work up to 90 per cent. efficiency at a moderate output, and 96 per cent. at full output. He maintained if they put down a network of mains and employed transformers to feed them, no transformer need work at less than a third of its output (where its efficiency was 85 per cent.), for the simple reason that when the output got less they could cut off a feeder and let the network be fed from the others. He would now like to say one word about the question of dynamos. He thought they would go away frightened at the size of the alternate-current machines if they took Mr. Gordon's figures, who spoke of a machine giving 200 kilo-watts, with an armature 10ft. in diameter. Now, the machine which was shown last Thursday on the board was of 60 kilo-watts, and the armature was 40in. diameter. It they built a machine on the same lines with a 6ft. armature it would give them 200 kilo-watts, and the machine would weigh about 800lb. per horse-power, which was less than a continuous-current machine. Several speakers had spoken about magnetic lag. He would be a bold man who said whether there was or there was not, because nobody had proved it; but he thought there was not, and his reason for so thinking was that if there were lag he could not see how any telephone could articulate. If there were lag, the lower the voice

going through the telephone the better they ought to hear. Now, as a matter of fact, they heard a high voice better than a low voice. The high voices have quick waves, and should be more distorted by lag, but they were not more distorted, and for this reason he was inclined to think that there was no lag, and until somebody showed him actually by experiments that that opinion was wrong he should hold it. Captain Carlisle, Mr. Bernstein had objected to the safety device which he put between the two coils, and Mr. Bernstein had characterized it as sending the primary current into temptation. Now, what was this temptation? It consisted of the presence of metal outside the primary circuit, but between this metal and the coil there was insulation. In what did this differ from the temptation which existed in every transformer? They had the metal in the secondary coils, and they had insulation between them and the primary. With the one itself it was just the same thing. And in what way was the strain brought on the insulation of the primary greater than that of the secondary as compared with the strain which was already brought on it by the presence of the core? They were bound to have iron somewhere, and whether they had it in the inside only, or on the inside and outside as well, the strain on the insulation was the same. So that he believed the objection was merely a sentimental one. Referring to the general question of batteries versus transformers he wished them to understand that he was at present in favour of the latter, simply because he had no confidence in batteries. If he knew batteries were good enough he would never presume to put down alternating plant, but he had never seen a good battery, and, therefore, that was the only way of doing the work. It was done everywhere. As Mr. Morley said, they might as well try to stop the sea as try to stop the employment of alternate currents. But in order to provide for the day when batteries would be good enough, they must put their plant down now so that most of it could be used later on. What would they have to throw away, and what could they retain? They could retain their boilers, engines, and stations. They could retain the whole of the network, and the whole of the distributing plant to the houses. What they had to throw away were their alternating dynamos and the transformers. Both together would not cost more than 10s. a lamp. The wiring and fitting of each lamp in a private house would cost at least 30s. to 35s.; the conductors would cost something like 30s. again, so they could see that by introducing alternating currents they would only risk a possible future sacrifice of about 10s. per lamp in an installation costing from £5 to £5 per lamp originally. Nearly the whole of their plant would remain equally as valuable when the day arrived that batteries could be used. Until then they would find the alternate current and transformer system good enough, safe and reliable for all practical requirements. It seemed to him that there really was no fault to find. They did not advocate a thing which was altogether wrong, and which would be altogether wrong in a few years. They advocated a thing which with a very little sacrifice would be good for the day when they had batteries.

Mr. Mackenzie said, in reply to Prof. Ayrton's query as to whether the coils he spoke of were ever actually tried at the Grosvenor Gallery installation, he could only say that some experiments had been made with an apparatus consisting of a single coil of fine wire placed in series with the primary of the series transformers then being used, in which coil was inserted a core formed of a bundle of iron wires, inserted more or less by hand as the output from the secondary of the transformer varied. No good results were, however, obtained, as the coils that were tried invariably got burnt up in course of time. The idea was abandoned, and no further experiments were made, it being decided about that time to put the transformers in parallel. Mr. Bernstein had suggested that his flexible contact plugs would serve as a means of putting the secondaries to earth should the potential rise above what was proper, and Mr. Mackenzie thought that such an arrangement was quite feasible, and would prove cheaper than the apparatus devised by Captain Carlisle, which was, however, in itself an excellent and ingenious contrivance; but he objected altogether to putting the secondaries to earth in an installation based on the transformer system, for reasons which were numerous, and had already been mentioned by previous speakers. Mr. Atkinson, in referring to the Kingdon dynamo, wondered whether Mr. Mackenzie had experienced in working this machine a large amount of alteration in the existing circuit, and this effect had in reality been observed, though not to any great extent, and was probably due to the causes mentioned by Mr. Atkinson. Mr. Kingdon, in stating that the fly-wheel of an engine was a part of his machine, did not intend to convey the impression that existing engines were preferable to those altered, but that in designing a dynamo for a central station, the fly-wheel of the engine, necessary to insure in any case steady running, would be made to form part of the dynamo, and thus combine two functions in one. The object of arranging the machines into various circuits, so as to admit of alterations in the coupling, was obvious, since batteries could be cut out of circuit as the output diminished, thus working the remainder at their maximum. There were many reasons why it would be advantageous to be able to alter the connections of the batteries, but the want of time prevented him going into the matter.

In answering Mr. Crompton's request to give him information regarding the efficiency of the transformer system, he thought that Mr. Crompton was at present asking for rather too much. As regards the saving of copper used by the employment of this system, referred to the diagram on the wall would make this clear, and he thought that many of the objections that had been raised by Mr. Crompton had been met and successfully answered by several speakers that evening. There would be no gainsaying the fact that the transformer system had made tremendous way, and this would never have been the case had not the system possessed merits placing it before all others in the general distribution of electricity. He quite expected to see Mr. Crompton before very long becoming as warm an advocate for the transformer system as he had not many years ago been an opponent of electrical distribution by secondary batteries. Mr. Gordon had put very fully into the relative merits of the two systems, but he had been

answered by several gentlemen who had joined in the discussion that evening, and the speaker was afraid he could not altogether agree to the conclusions Mr. Glanville had arrived at. Prof. Sylvanus Thompson, as well as Mr. Morley and Mr. Matgen, had called attention to his statement regarding the Faraday theory. He wished to point out that the words "reflected" by Ruhmkorff should be "transmitted" by Ruhmkorff. M. Glanville never having dreamed of denying the Faraday theory of induction, as such would have been shown on the face of it, but he distinctly laid down the claim that the Ruhmkorff coil more or less modified formed the basis upon which all previous experiments had worked, and had consequently been utterly unsuccessful. Regarding Mr. Matgen's mention of Jablochkoff, he believed that that electrician had ever conceived the idea of a trans-former system as now existed. He quite recollected the apparatus exhibited by M. Jablochkoff in Paris at the great International Electric Exposition of 1881, but the system then shown at work as a "transformer system" was no more either theoretically or practically like what Glanville had described than a Waukesha machine was like a dynamo, and he did not think the subject worth discussion. Prof. Thompson had objected to his statement that when one transformer only was connected to a dynamo it was "either in parallel or series," but he did not see how any one could prove the contrary, in spite of the argument brought forward by the Professor, since like a "parallel," it took more than one to make a parallel or series circuit. Seeing the hour was so late, he was unable to say more in answer to the remarks made by the numerous gentlemen who had joined in the discussion.

PROVISIONAL PATENTS, 1888.

MARCH 17.

4144. Improvements in or relating to mariners' compasses. Thomas Harrison, 6, Lord-street, Liverpool.
4153. Improvements in means for regulating or controlling the secondary current derived from continuous electric current transformers. Frank King, 47, Lincoln's Inn fields, London.
4171. Electrical governor for motive power engines. William Spies Freeman, Gray's Inn Chambers, 20, High Holborn, London, W.C.

MARCH 19.

4177. Improvements connected with insulators for the purpose of regulating the tension of telegraph and telephone line wires. Edward Barnes, Commercial-street, Halifax.
4188. An improvement connected with arc lamps whereby the controlling mechanism is contained in a box four inches deep or thereabouts. Frederick John Beaumont, 42, Trinity-square, Boro', and John Kent, 9 and 10, Railway Approach, London Bridge, S.E.
4208. Improvements in apparatus for opening doors by pneumatic or electrical agency. Carl Wilhelm Friedrich Thoen, 22, Southampton-buildings, Chancery-lane.
4222. A regulating appliance for dynamo-electric machines worked by gas motor or other engines. Henry Percy Holt, 29, Southampton-buildings, Chancery lane, London, W.C.

MARCH 20.

4240. Improved apparatus for the making and breaking of contact in electrical appliances, especially applicable for burglar alarms, and instead of pushes for ringing electric bells. Henry Bowditch Yandley, 17, Clarendon-villas, Church-lane, Old Charlton, Kent.
4270. Improvements in the method of and apparatus for controlling or regulating the movement of electro dynamic motors, or of machinery or apparatus propelled or driven thereby. Bradley Allan Fiske, 23, Southampton buildings, Middlesex.
4274. Improvements in or relating to storage batteries. William Phillips Thompson, 6, Lord-street, Liverpool. (Class. David Paige Gibson, United States.) (Complete specification.)
4275. Improvements in or relating to storage batteries. William Phillips Thompson, 6, Lord-street, Liverpool. (Class. David Paige Gibson, United States.) (Complete specification.)
4292. An improved switch and fuse for electric light and other purposes. Charles Edward Gilet Gilbert, 79, Amhurst-road, Hackney, E.
4294. An harmonic commutator for alternating currents. Ambrose Myall, 21, Cockspur-street, Middlesex. (Walter Judd, Hong Kong.)

MARCH 21.

4317. An electric lamp and bell, and improvements in electric lamps. Japh John Mason, 5, St. Mary's street, Lincoln.
4330. An improvement in dynamo-motors. Paul Fuess, 47, Lincoln's Inn-fields, London.
4345. Improvements in the method of and apparatus for distributing electrical energy by alternating currents from central stations. Gilbert Kapp, 70, Market-street, Manchester.
4353. Improvements in electric telegraph insulators, and in the manufacture thereof. Ernest Wentworth Butler, 33, Queen-street, London, E.C.

MARCH 22.

4393. Improvements in and relating to the control of electric currents. William Spies Freeman, Gray's Inn chambers, 20, High Holborn, London, W.C.
4425. Improvements in dynamo-electric machines or motors. Patrick James Charles Lister Hanson, and Robert Henry Power, 24, Southampton buildings, Chancery lane, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MARCH 18, 1887.

4116. Improvements in electric incandescent lamps, and in the method of manufacturing the same. Arthur French St. George and Christin Ras Deane, 26, Mark lane.

MARCH 31, 1887.

4795. "Direct motor wheel" for the driving of carriages, dynamos, or machinery. Frederick Fawson Lee, The Close, Salisbury.

APRIL 22, 1887.

5862. Simultaneous driving of a number of clocks by magneto electricity. William Blenheim, Engeströmd Green, Egham, Surrey.

APRIL 23, 1887.

5958. Improvements in dynamo-electric and magneto-electric machines. Alexander Melville Clark, 53, Chancery-lane, London.

MAY 9, 1887.

6754. Improvements in and connected with dynamo electric machines. Robert Evelyn Bell Crompton and James Swinburns, Art Works, Chisleham.

MAY 11, 1887.

6917. Improvements in electric transformers induction coils, or inductive resistance coils. William Morris Morley and Charles Edmund Webber, 47, Lincoln's Inn fields, London, W.C.

MAY 12, 1887.

6987. Improvements in electric arc lamps. Alexander Stott, 28, Southampton buildings, Chancery lane, London, W.C.

MAY 13, 1887.

7021. Improvements in electro-dynamic and dynamo-electric machines. George Seantett, 6, Lord-street, Liverpool.

NOVEMBER 4, 1887.

- 15,056. An improved multiple electric cable. James Alexander Betts, 53, Chancery lane, London.

JANUARY 12, 1888.

506. Improvements in the construction of suspension fittings for incandescent electric lamps. Charles Mark Dore and Reginald Arthur Smith, 24, Brazzaville street, Manchester.

JANUARY 17, 1888.

750. Improvements in and relating to electric railways and to vehicles for use thereon. Henry Harris Lake, 45, Southampton buildings, London. David Gustavus Weems, United States.)

SPECIFICATIONS PUBLISHED.

COMPANIES' MEETINGS.

DIRECT SPANISH TELEGRAPH COMPANY.

The twenty-ninth ordinary general meeting of the Direct Spanish Telegraph Company (Limited) was held on Monday at Winchester House, Old Broad-street, E.C.

Mr. James Anderson presided, and said their revenue had increased by £1,338, notwithstanding the fact that their traffic on the Barcelona section had fallen off owing to the absence of speculation, therefore this traffic was nearly all due to other parts of Spain, and he might further add that the last three months of the present year showed a still further increase of £250. That was estimating the amount taking into account the Easter week, which was always a small one, so that he hoped next year they would get to a 5 per cent. dividend on the ordinary shares. It only required £600 to pay 1 per cent. on the ordinary shares, and he did not see why they should not get to the amount he had stated, seeing that the trade of Spain was improving. There had been a decrease of 10 per cent. in what was most important, they had been able to place £3,417 to the reserve fund; £5,000 had been invested in North Bridge Railway Four per cent. Debenture Stock, and in Threemonths-half per cent. Liverpool Corporation Stock, which had increased in value £255 since they bought it. He hoped that next time they would be able to print their reserve, showing at a glance what their reserve was invested in. The directors stated at the last meeting that they were getting a direct wire from Madrid to Bilbao, and when that was finished they hoped they would get a still further improvement in the traffic. Nothing increased the use of telegraphy more than rapidity of transmission and security. Their average time from Bilbao to London was only five minutes, and that left nothing to be desired, but if they got a special wire they would get through in five or seven minutes to Madrid, and then he thought they ought to have some further improvement in their trade. The company was prosperous; they were working at a very low tariff, and yet they were increasing their revenue. Last time the traffic had fallen off for the previous three months, now he had to tell them it was increasing, and but for the Easter week, which Mr. Gerhardt had estimated in the present three weeks, they would have had a half per cent. already earned. He thought in time the Direct Spanish would stand equal to any other telegraph company in the city of London. He moved the adoption of the report.

Mr. Estinger seconded the motion, and it was carried.

A dividend at the rate of 10 per cent. per annum was declared on the preference shares, and of 2 1/2 per cent. on the ordinary shares (free of income tax), making 4 per cent. for the year.

CITY NOTES.

Maxim-Weston Company. The Maxim Weston Electric Company shows a net profit for the year, including £139, brought forward, of £1,555.

Brazilian Submarine Telegraph Company. The traffic receipts of the Brazilian Submarine Telegraph Company for the week ended March 23 amounted to £5,094.

The Schanckhoff Company. We are informed says the *Financial News*, that the capital of the Schanckhoff Electric Light and Power Company Limited has been fully subscribed.

Direct United States Cable Company.—The board of the Direct United States Cable Company have resolved upon the payment of an interim dividend at 2s per share, free of income tax, being at the rate of 2 per cent. per annum for the quarter ending March 31, 1888, such dividend to be payable on and after April 24 next.

Globe Telegraph Company. The directors of the Globe Telegraph Company have declared the payment of an interim dividend on the preference shares of 3s less income tax, and at 2s on the ordinary shares, the income tax having already been deducted, payable on the 18th proximo for the quarter ending April 18, 1888.

The Schanckhoff Electric Light and Power Company, Limited. A new company has been registered under this title, with a capital of £200,000 in 40,000 shares of £5 each. The directors are:

The Right Hon. Earl Cathcart, Thornton-le-Street, near Thirsk, York-shire (chairman).

Walterforce Bryant, Esq. (chairman, Bryant and May, Limited).

Lieut. Col. The Hon. H. W. Campbell, Director, London and South-Western Railway Company.

David Marks, Esq. (Director, Northumberland Land and Coal Company, Limited).

Otto H. Trummer, Esq. (Director, Bryant and May, Limited).

(All the Directors are interested as Vendors.)

The prospectus states that the Company is formed to purchase from the Schanckhoff Electric Battery Syndicate Limited, the patent rights for the United Kingdom, France, Belgium, Germany, Italy, United States of America, and India for the Schanckhoff Single Lead Battery, and also the benefit of applications for patents in respect of the inventions, which have already been made by the syndicate in many other countries, together with the right to patent the invention in all other countries in the world in which patents or similar rights can be obtained subject to the half interest reserved to the vendors in the patents other than that for the United Kingdom.

NOTES.

The "Benbow."—Like all new vessels of any proportions, this magnificent ship is fitted throughout with the electric light.

Electric Lighting of a Theatre.—The Gas Company of Beziers (Herauld) is about to carry out the electric lighting of the theatre in this town.

United Telephone Company.—The United Telephone Company have taken advantage of the Easter holidays to make certain improvements and alterations in their switch-room.

Telephonic Development.—Mr. A. R. Bennett read a paper on recent developments in telephony at the fortnightly meeting of the East of Scotland Engineering Association last Tuesday.

Society of Telegraph-Engineers.—The paper to be read at next Thursday's meeting of the society is on "Central Station Lighting" (Transformers & Accumulators), by R. E. Crompton, M.I.C.E.

Electric Traction.—An experimental tramcar has been successfully run at Paisley from Inch-street to the Cross. The electrical part of the car is according to the designs of Mr. James Gibson, of Paisley.

Electric Lighting of Trains. The London and Brighton Railway Company have now fifteen trains lighted by electricity, two running between London and Brighton, and thirteen others which are local.

Welsh Gold Mines.—According to various reports, the returns from these mines are extremely favourable, and in order that the work may be carried on more quickly, electric light apparatus is being installed at the Gwyn Iydwdd Mine, by means of which the mine and premises are to be lighted.

Wonderful.—An American town, Urbano, O., recently advertised for tenders for 15 to 40 arc lights and 100 incandescent lights, and maintenance for five years; but, wonderful to relate, the Town Club did not receive a single tender. Are all the companies full of work; or is there more in this than meets the eye?

Barcelona Exhibition.—The illuminated fountains, which will be an interesting feature of this exhibition, will be erected and run by the Anglo-American Brush Electric Light Corporation, who have entered into a contract with the authorities to provide fountains similar to those which excited so much admiration at the recent South Kensington Exhibition.

Storms in Eastern France. Violent thunderstorms have been scaring the population of Nancy and its neighbourhood, and one death—that of a farmer—is already reported. He was struck by lightning as he was returning home after his work, and his family, alarmed at his protracted absence, went in search of him. His body was not found until a late hour in the evening.

Gas Sometimes Fails. A correspondent says—Shortly after the commencement of the service at Holy Trinity church, Boston, the other Sunday evening, the gas went out, owing to water in the pipes, and but for the candles at the reading desk, the congregation would have been in total darkness. The gas was re-lighted but went out again almost immediately. The service was therefore abruptly closed and many of the congregation repaired to the parish church.

Exeter and the Electric Light.—At the meeting of the Exeter Town Council, last week, a memorial was read from over 3,000 citizens, asking the Council to take steps with a view to the adoption of the electric light as an illuminant for that city. One of the systems of electric lighting has been for some time in use in some of the main streets, and the citizens seem much pleased with it. The Council resolved to take steps to ascertain the cost, and various other particulars.

Telegraph Officials.—It having been brought under the notice of the Lords at the Treasury that the system of paying fortnightly the staff at the London Central Telegraph Office involved an extra expenditure of one day's pay in every ordinary year of 365 days, and of two days in every leap-year, to those of the clerks earning a yearly salary, their lordships have issued an order to the effect that in future the salaries are to be paid monthly. The gain to the Treasury would have amounted to nearly £600 for the past year.

Easingwold.—The contract for lighting the mansion of J. H. Love, Esq., The Hawkhill, Easingwold, Yorkshire, has been placed in the hands of the United Electrical Engineering Company, Limited. The installation will be a large one, consisting of about two hundred 16 c. p. lamps. The power will be supplied from a steam engine and boiler to be erected by the contractor in a small engine house built for the purpose. A set of accumulators will be provided to keep 90 to 100 lamps running from eight to nine hours.

Bradford. In our advertisement columns will be found an advertisement from the borough of Bradford relating to tenders for electric lighting. The action of Bradford is commendable from all points of view. The Corporation owns the gasworks, but an independent company started electric lighting, and it was seen that from many points of view the latter had possibilities superior to gas; hence, it was decided to make a practical experiment to determine the exact value of such a light and its cost for general lighting purposes.

University College, Bristol.—The Students' Engineering Society of this college concluded the winter session on March 26th with a public disputation on the gas engine, the steam engine, and on March 27th with a *concertation*. Mr. de Seyres occupied the chair on the first night and Mr. Albert Fry on the second. The electrical and engineering exhibits attracted much attention, and a highly-appreciated concert was rendered by the students and their friends. The proceedings were concluded by a short address to the departing members by Dr. Ryan, president of the society.

The Telephone in Peru.—The Peruvian Government is putting up to auction the construction and working of telephone networks over the whole extent of the Republic. The main stipulations are the following:—An exclusive concession for 15 years. Payment for the construction of lines by subscribers, according to a fixed price per kilometre. Permission to fix supports for the lines on the roofs of public buildings. Gratuitous use of a line by the Palace of the Prefecture. Tenders should reach Lima prior to the 23rd prox. Preference will be given to tenders proposing the lowest tariffs for subscribers.

Madrid.—The new regulations for the Madrid theatres were published on the 31st March. Among other things they prohibit the use of gas, and make the adoption of the electric light within six months compulsory. A large business has been done in Spain by English manufacturers in

other branches of mathematical engineering, and we trust the various electric light firms have secured good representatives in that country. The Royal decree states that all dynamos, engines and motors of any kind are to be completely isolated from the main building, and in fact stringent rules are laid down to render the installations safe. The supplementary lamps are to be oil lamps.

Civil Service Stores.—An installation of 372 incandescent and two arc lamps has been completed at the Civil Service Stores in Queen Victoria-street. The dynamo is one of Elwell-Parker's inverted B type, driven by one of Davey-Paxman's compound vertical engines of 16 h.p. The two Essex boilers are also by Messrs. Davey-Paxman. About four miles of wire have been used, and this is cased throughout. The whole of the installation has been carried out under the direction of Mr. Goddard, chief engineer to the Civil Service Association, and has proved very satisfactory. The dynamo ran last week from Thursday morning till Saturday night without difficulty.

Phono Signals in Submarine Telegraphy.—A telephone, placed in the circuit of a submarine cable through which the ordinary signals are being transmitted, is affected by the currents passing; although the vibrating of the diaphragm may not be perceptible to the ear, for the well-known reason that a minimum of twenty vibrations per second is requisite to produce an audible sound. But if an interruptor, breaking the current more than twenty times per second, be also inserted in the circuit, an undulating sound is conveyed to the ear by the telephone. On this principle, M. Ador has constructed an apparatus which allows of the employment of phonetic signals in submarine telegraphy.

Electric Welding.—Prof. A. E. Dolbear writes:—"I have had made nearly a hundred tests of the tensile strength of electrically-welded bars of iron, steel, and other metals. The results were of such a character that I can state positively that with Thomson's welding process it is possible to weld both wrought iron and steel so that the weld is as strong as the same cross-section in another part of the bar. I had a number of bars welded by an expert blacksmith and a number of similar ones by the electrical process for comparison, with the result that the electrically-welded bars were much stronger than those welded by the ordinary process. The bars were of various sizes, up to an inch and a half for iron, and three-fourths of an inch for octagon steel."

The "Star" Paragraph.—A contributor, growing satirically eloquent over the mutual admiration society referred to by the *Star*, bursts into the following verse, which he says aptly describes one man's feelings:—

"But I car'd not for that the worth of a shilling,
Well knowing my friends are both ready and willing
With proxies O.K. in support of my wishes,
While I keep the keys to the loaves and fishes.
If Nature had not on the whole of our class
Most kindly bestowed a profusion of brass,
I'd feel quite ashamed to exhibit my face
In front of the husband, but then there's my place;
So we'll stick to each other and cannot then fall,
For we've cheek, and we've bounce—and the chink, that
is all."

The metre is somewhat shaky, but it may pass.

Kensington.—The Works Committee have considered the draft license proposed by the Kensington Court Electric Light Company, and, after conference with the engineer and solicitor, suggest the following alterations to

the Board of Trade:—"In clause 7 (section c), authorising the carrying of the line over or across any street, the addition of the word 'bridge.' In clause 10, relating to interference with any sewer, drain, watercourse, defence, or similar work under the jurisdiction or control of the board, the insertion of the words, 'or work in connection with such sewer or drain, such as ventilating shafts, manholes, side entrances and gullies;' also a provision that any consent given by the board should be in writing." The board approved the action of the committee.

Vagaries of Lightning.—During a hailstorm at Mors, in Denmark, a few days ago, a flash of forked lightning the only one occurring struck a farm, and having demolished the chimney-stack and made a wreck of the loft, descended into the living rooms on the ground floor below. Here its career appears to have been most extraordinary, all the plaster around doors and windows having been torn down, and the bed curtains in the bedrooms rent to pieces. An old Dutch clock was smashed into atoms, but a canary and cage hanging a few inches from it were quite uninjured. The lightning also broke 60 windows and all the mirrors in the house. On leaving the rooms it passed clean through the door into the yard, where it killed a cat, two fowls, and a pig, and then buried itself in the earth. In one of the rooms were two women, both of whom were struck to the ground, but neither was injured.

A New Electric Launch.—A great sensation was produced on the occasion of the recent Oxford and Cambridge boat race by an electric launch, due to the Electrical Power Storage Co., and worked by their accumulators. "At last," says a non-technical contemporary, "a really useful electric launch has been produced, and the noisy, dirty accessories of steam and coal on the Thames will be reduced." The vessel can accommodate 20 people, and will attain a speed of 11 knots an hour on the tide-way. The means of propulsion are not visible, for the accumulators are placed under the seats, and the motor is at the bottom of the vessel. The launch is completely under control, and by just turning an indicator handle can be driven at half or full speed forwards or backwards. Sufficient energy is stored for driving at full speed for eight hours or half speed for 18. It is proposed to erect charging stations at points up the Thames, so that launches going for a protracted trip may be re-filled.

Leamington.—Further alterations and improvements are about to be introduced by the Midland Electric Lighting Company into the lighting of the Parade. It is proposed to substitute, in place of the 16 candle-power Swan lamps now in use, 32 candle-power lamps, and to reduce the number of lamp-posts by about one-half. An alteration is also to be effected in the mode of hanging the lamps, which will not be suspended from the end of a long arm, but will be enclosed in a globe placed on the top of the supporting column. The globe will be 2ft. in diameter, the upper part opal, and the lower part frosted glass. The shape of the lamp will thus be hidden, and only the bright light irradiating from the globe on all sides will be seen. No general alteration will be made, and none is necessary, in the lighting of the shops and private houses, where the light is much appreciated. The company, however, do not bind their customers to any kind of lamp. The works in Wise-street are fast approaching completion, and Messrs. Chamberlain and Hookham are sparing neither trouble nor expense to make the lighting of the town a success.

Train Signalling.—The practical value of the induction system of train telegraphy, says *Engineering News*, by which messages can be sent from moving trains, was well illustrated by its workings on the Lehigh Valley Railroad in the great blizzard. The regular telegraph lines were all down, but the induction line, which has been in use upon the New Jersey division, from Perth Amboy to Easton, for several months past, worked excellently throughout. In one accident, near Three Bridges, the induction train telegraph operator at once telegraphed back for a wrecking train, which soon arrived; and during the entire day messages were sent to and from the wrecking train, and surgical relief was obtained. All the beleaguered passenger trains, every one of which was equipped with the new system, were located by means of train telegraphy, and provisions were sent to the hungry passengers. More than two hundred messages were sent back and forth over the single line of the company during the three days of the storm by belated passengers and others. The poles used to carry the line are only 16ft. high, and expose little surface to the storm. The messages are transmitted by induction from the metal roof of the car to the line, a distance of 10ft., and even when cars and line were both buried in the drifts no inconvenience was suffered, as the dry snow did not interfere with the induction.

An Amusing Telephone Story.—A funny story is told of the telephone. A cement manufacturer some miles below London Bridge was lately placed in circuit. He is rather high-tempered and easily provoked. His foreman is old, short sighted, and somewhat dull of hearing. The latter has sometimes to go to the master's private office for instructions. The other day he saw his master was alone, and, all oblivious of the new means of communication, he stood himself on the mat outside at the open door.

Master to instrument. Hallo! What is it you want?

Man at door.—I want to know how many barrow-loads of stuff—

Master to man. Will you be quiet there for a minute? To the instrument.—Eh? I didn't catch what you said.

Man.—It's about that stuff we've been a workin' on, and it's time.

Master to man.—Will you be quiet, will you? I'm not speaking to you. To the instrument (loud). Repeat that, please. I can't hear well.

Man at door (louder than ever). If you're a-going to put that 'ere stuff in, sir. We want to know.

Master to man (louder than ever). Oh dear, will you shut up, you old fool? Don't you see that I'm engaged?

Hanging up the receiver, he slammed the door in the foreman's face. When he returned he could get no further communication. The man thinks his master was out of his mind, talking to himself in that dreadful way. The master wonders why the man at the other end didn't finish his message, and thinks the telephone's no good. The man at the other end is waiting for an explanation as to the strange replies he received when he was trying to send on an order for cement by telephone, and has placed it elsewhere.

Electric Tramway.—Some time ago, says the Vienna correspondent of *Industries*, I reported the inauguration of a short experimental electric tramway line from the Central Station along the Königsgasse and part of the Ringstrasse, the total length being 1.1 kilometres. The service on this line has now for some months been perfect. The generating dynamo is established in a shed near the railway station, and the current is supplied by means of a central channel and a pair of conductors against which slide two contact shuttles. There are at present only two cars in use. These are of the same type as those

on the Lichterfelder tramway near Berlin. The transmission of power from the motor spindle to the car axle is by steel wire spiral cords. The central channel is of masonry throughout, with cast iron chairs for the support of the conductors, and has two steel rails on the top, leaving a slot 1½ in. wide. Manholes are provided in several places to give access to the channel, and efficient provision is made for draining it. Messrs. Siemens and Halske, who have built this line, are now experimenting with various forms of contact shuttle. They have asked for a concession to extend the line the whole length of the Grosse Ringstrasse, now building, and they also made an offer to the town authorities to build, and equip with electric apparatus, several tramway lines which were originally projected for steam traction. In all cases they ask that the usual concession of forty years should be prolonged to fifty years, the extension of time being justified by the heavy initial outlay for the permanent way.

Carbons for Arc Lamps.—The manufacture of arc light carbons forms an industry of considerable magnitude, and the works of Herr Hardtmuth, in Döbling, says *Industries*, are now turning out about 3,500 metres of carbons daily. Some improvements have recently been made in the process of manufacture, under which the homogeneity and density of the carbons are increased. These refer more especially to cored carbons. As usual, the rod of plastic material issues from the press in the form of a tube, and after drying and baking, the carbons are steeped in a heavy hydrocarbon, by which the pores left after the first baking are filled. The carbons are again baked, and the core is then inserted under a pressure not much greater than that of the weight of the plastic mass forming the core. In connection with this factory is a well equipped electrical laboratory for the testing of arc lamps. There are dynamo machines by various makers—viz., Pöge, of Chemnitz; Kremenezky, Mayer, and Co., of Vienna; Krizik, of Prague; and Siemens and Halske (alternator). The reason for installing various dynamos is to be able to test any lamp which may be sent to the laboratory. There is also a spectro-scope for determining the elements contained in the carbon from the spectrum of the arc, and the laboratory is equipped with the usual electrical measuring instruments and photometers. The work at this laboratory is done on a thoroughly scientific basis, and both lamps and carbons are tested so as to determine the best quality of carbon to be used for each type of lamp. At the forthcoming Jubilee Exhibition, Hardtmuth carbons will be largely used for the arc lamps.

Traction by Accumulators.—In our issue of the 23rd ult., under the heading "The Brussels Tramways," we noticed the unsuccessful results obtained with the cars, worked by accumulators, on the tramway between the Rue Belliard and the Place Royale, and subsequently on the tramway along the Rue de la Loi. The *Moniteur Industriel*, which has always been "dead against" the use of accumulators for traction, regarding it as the most complicated and costly means of applying electrical power for the purpose, considers that this failure affords conclusive evidence in support of the position it has taken up, and an absolute condemnation of the decision of the special jury at the Antwerp Exhibition to the effect that the system of working by accumulators is superior to all others—a decision which it characterises as *idiotic*. Our contemporary holds, moreover, that, up to the present time, the accumulators which

have been employed for traction may indifferently be regarded as "not good for much," though it admits that a type of accumulators susceptible of being economically worked may some day be forthcoming. From the report of the Brussels Tramway Co. it appears that the use of electricity during last year resulted in a loss, for the three cars which have been referred to, of 15,876 francs, or of 5,292*l.* per car, and that the maintenance of the accumulators, after deducting general expenses, amounted to 22 centimes per car-kilometer, i.e., to more than the cost of animal traction inclusive of general expenses. The conditions of working on the tramway along the Rue de la Loi, which is in a straight line and almost level, are considered as exceptionally favourable. Before endorsing the conclusions of our contemporary we should require some comparative data as to the particular type of accumulator employed on the Brussels tramways, and as to the system employed in charging and working it.

Hamburg.—The town electric works offer to supply private consumers with current available from 12 noon to sunrise the next morning, on the following conditions. Connections will be made and kept up by the works at the expense of the consumer at rates to be determined each year by the authorities. The meters are to be supplied by the works, and may be bought or hired by the consumer; so will glow and arc lamps and carbons be kept in stock. Lamps procured by the consumer elsewhere must correspond in type to the current supplied. Repairs in hired meters fall on the works; in bought meters, on the consumer. Small repairs in wires, lamps, &c., supplied by the works, not to be charged. Notice must at once be given of anything wrong. If heating sets in, the current must be cut off, and only restored under direction of the management. The meter will be read weekly as a rule, but never seldom than once a month. The rate for current will be by meter 4*pf.* per 50 volt ampere-hour (9*gd.* per Board of Trade unit), which corresponds to about $\frac{1}{5}$ shilling per 16-candle glow lamp per hour; or to $\frac{1}{2}$ shilling per 600-candle arc lamp per hour. Odd numbers of arc lamps to be charged as the next even number. The consumer, also, will pay 5*s.* per glow lamp, 10*s.* per arc lamp per annum; this will become 2*s.* 6*d.* and 5*s.* respectively if the consumer uses all his lamps an average of 2½ hours each; and will be reduced to nothing if the consumer has a daily average of 3 hours per lamp. The town reserves the right to revise the prices at the end of each year, and at any time to entertain applications for electricity for any other purposes than lighting, and to sell the same at any other price than that charged for lighting. No credits beyond eight days—otherwise, "cut off." Security for the cost must be given before the current will be introduced. The supply may also be cut off if access be denied to any room in which wires are laid. Notice is to be given of the intention to cease using the current: if this be not done, the consumer will continue liable for the meter rent.

A Pillar of Light at Sea.—According to a "Seafarer," writing in the *Daily Telegraph*, the master of a Spanish steamer that lately arrived at an English port from the east coast of South America, has given particulars of a very interesting luminous appearance, probably electrical, that was encountered by him about 100 miles south of the equator. He was in his cabin, he says, when he was awakened by his chief officer, who begged him to step on deck at once to view and pronounce upon a singular light, towards which the steamer was directly heading. The mate added that he had slowed the engines

down, as he did not like the idea of running into that strange shining on his own responsibility. The captain mounted to the bridge, and looking ahead, witnessed a very extraordinary sight. The sea was calm, with a light swell rolling from the east; the time was shortly after midnight, the sky was dark and starless, yet the dusk was clear—that is to say, a ship's lights, for example, would have been visible for a considerable distance. Right on a line with the bows of the steamer there stood, or seemed to stand, a vast shaft of pale-greenish light, apparently about three-quarters of a mile broad, and, owing to the nearness of the vessel to it, seemingly elevated to the height of about forty-five degrees. Its outline was defined with singular clearness upon the blackness that was on either hand of it, and above and into whose folds there entered, doubtless from contrast, a deeper dye of gloom. There was no distortion whatever, no curvature in the oblong form of the luminous appearance. It was reared like some substantial object that had been coated with phosphorus. The Spanish captain collecting, after a brief glance, the character of the space of brightness, signalled to the engine room to go full speed ahead, and presently the ship steamed into the glittering volume. It was noticeable that although, when quite close to the body, the vessel continued in blackness, proving, at least, to the satisfaction of the Spanish captain, that the light possessed no powers of externally illuminating, the moment the ship had driven into the thick of it everything was as plain aboard her as though she had been bathed in soft waning moonlight. The ship occupied about seven minutes in steaming through this shaft of light; she then emerged into the blackness of the night again, leaving the radiance shining very clearly over her stern, where it gradually narrowed and grew dimmer as it receded, until it died out in the distance.

Philadelphia. The Edison Electric Light Company of this city are erecting the largest station for lighting in this country. As this station is to supply the central portion of the city, the land on which it is built is very valuable; it was, therefore, necessary to limit the area to 70*ft.* by 100*ft.* In order to get the required space, the building is carried up 114*ft.* above the pavement, and is divided into six storeys. On the ground floor will be located 20 engines of 250 I.-H. P. each. They are of the Armington-Sims type, running at 200 revolutions per minute. The foundation for the engines will be practically solid with the concrete foundation of the building. On the second floor will be forty dynamos of 1,500 lights each, making the total capacity of the station 60,000 16 c.-p. lamps. The dynamos will weigh about 7 tons each, and will run at a speed of 650 revolutions per minute. On the third floor will be the work shops, where wires and conduits are prepared for laying in the streets and making connections with houses. On this floor will also be located the two blast fans, driving 50,000 cubic feet of air per minute into the furnaces. The products of combustion will be discharged by means of two shafts, 9*ft.* in diameter, and so built on either side of the house as to resemble huge bow windows starting from the third floor. On the fourth floor will be placed the boilers. Their rated capacity is 5,000 h.-p., and they are to be of the Abendroth and Root tubular pattern. The smoke will be discharged downwards into the flues on the third floor, and the ashes, which will fall into pyramidal ash pans, will be discharged into cans on the same floor. On the fifth floor there is storage capacity for 1,000 tons of coal. The arrangements are such that on the first

floor the coal waggons are driven on to scales. After being weighed the coal is discharged into shoots, delivering directly into elevators, which carry it to the fifth floor, where it is shot into the bins. Arrangements are made for delivering the coal directly in front of each boiler. On the sixth or top floor will be the general offices of the company. The distribution is to be on the three wire system, and there are thirty-five mains leading out of this station. The company has already expended £40,000 for copper conductors, and eleven miles of street mains have been laid, leaving about twenty miles more to cover the district. This quantity will be laid during the coming summer. The station when finished will cost £200,000. Arrangements have already been entered into to furnish upwards of 10,000 lamps, and as the company intends furnishing power in any quantity that may be desired up to 100 h.p., there is no doubt but that the venture will be a financial success. —*Industries.*

Weston-super-Mare. It will be remembered that some experimental lighting has been carried out at Weston, but the powers that were did not view the proposal of a permanent installation with favour. The future of electric lighting, however, seems favourable in that some of the candidates at the Local Board election have thought necessary to mention the subject of the light in their addresses. Thus the Rev. W. Boyden said:—"In reference to one matter he was at issue with a large number of the members of the present Board—he meant the electric lighting of the town. He was very sorry the Town Commissioners thought it to be their duty to ignore the wishes of a public meeting—a large and influential meeting—and to set at naught the opinions of all the medical men of the town, and to snuff it out. He thought they were treated with scant courtesy. Now, that was one of the things in his estimation which might have rendered the town increasingly attractive, and have had a tendency to draw thousands of visitors to it during the coming season. He believed that one objector to electric light on the Board said that it was in its infancy; nevertheless, infancy is the period of interest. When electric light had lost its novelty, and everybody had adopted it, it would be of precious little use introduced into Weston as an attraction to outsiders. Now was the time when it might have been applied to advantage. He knew it was not altogether thrown out of court, as there was an intimation that the Commissioners might do something on their own account, but he owned it would have been much better to have accepted the contract with the proviso. Perhaps if the Board went in for an experiment it might turn out like the experiment at the ventilation of the sewers, which was costly and unsatisfactory. Then the cost of the electric light was not very serious; it was placed before them in the press. He would have been much more pleased to have seen a system introduced, and to have saved something which appeared to him to be wastefully expended at the present moment." On the other hand, Mr. Jesse Shorney, an old member of the local board, said, with regard to the electric light, he would be pleased to see it introduced into Weston super Mare, if it could be done with the money the board had at their disposal. The lighting the sea front by electricity would add another twopence to the rates, and to light the whole town would necessitate an increase of from 4d. to 5d. a pound, hence he thought it was wise to postpone the question for twelve months, during which time something better, if not cheaper, might come up. When we see

electric lighting made thus prominent in local elections, matters must be progressing.

Lighting the Suez Canal.—The *Times* of March 20, in an article on this subject, says a scheme has been formulated, having a twofold character, which is now being carried into practical effect. Firstly, the canal itself is to be lighted, throughout its entire length, with such lights as will enable vessels to keep their proper course with certainty; and, secondly, all ships navigating the canal by night are to be provided with such a system of electric lighting as shall meet the approval of the Company. The latter has been carried into effect—as is well known—before the former. At one time, also, there were rumours that the canal was to be electrically lighted throughout, and that transformers would be used. It seems, however, that compressed gas is to be used, and that to a large extent. The Pintsch's system of such lighting will be followed. After having described the canal lighting, the *Times* says: "Having described the arrangements for illuminating the waterway of the Canal, we will now turn to the equipment of the ships which will traverse it by night, and the conditions under which they will be permitted to avail themselves of this privilege. Steamers will be allowed by the regulations for the night passage to proceed under the same conditions as those laid down for the traffic by day, but with certain additional arrangements. In the first place, they must show to the satisfaction of the officials of the Canal Company, either at Port Said or at Port Tewfik, that they are provided with an electric projection at the stem or fore part of the vessel capable of throwing a light for 1,200 metres. They must also have an electric light, with a shade suspended over the deck, and capable of illuminating a circular field about 200 metres in diameter. The company's officials will decide whether or not the apparatus carried fulfils the required conditions, and whether or not it affords a sufficient guarantee for the steamer carrying it to be safely authorised to proceed through the canal by night. If in navigating by night a steamer receives an order to go into a siding, she must immediately on obeying the order extinguish all her electric lights and show only the regular signal lights of a vessel lying at a siding during the night, namely, a white light at stem and stern and a watch or anchor light. When two or more steamers provided with the necessary electric light are passing through the Canal by night in the same direction, if one of them is stopped she must immediately hoist a red light at the mizen masthead and give three short quick blasts with her whistle, which must be repeated at intervals of a few seconds until the steamer following acknowledges her signal by repeating it. These signals require the immediate slackening of speed, to enable the vessel to stop should it be necessary. The dredgers of the company, when at work, are to be guided by special instructions, and to be signalled by means of a whistle. They are also required to extinguish all electric lights when lying at the sidings. The lights to be used at the stations for signalling to passing steamers are of three kinds. To slacken speed three white lights, one above the other, will be employed; to go into the siding two white lights, one above the other, will be shown; and to pass one white light only will be exhibited. When these signals are addressed to a vessel coming from the north, a fixed red light will be placed above the white lights. When, on the contrary, they are addressed to a vessel coming from the south, the red light will be placed under the white lights."

SOME POINTS IN THE MECHANICAL CONSTRUCTION OF DYNAMOS.*

Some time ago we published, under this heading, an article in which we drew attention to the necessity of constructing dynamos, not only with regard to electrical, but also with regard to mechanical requirements; and we dwelt more especially upon the importance of supporting the armature core in a substantial manner, and employing a spindle of ample size and suitable shape. Dynamo makers sometimes neglect these points, and a machine which is electrically and magnetically all that could be desired fails from some purely mechanical defect which, with a little forethought, could easily have been avoided. Let any of our readers examine half a dozen dynamos of the same classified output, and as nearly as possible of the same speed, but by different makers, and he will speedily come to the conclusion that there is no system whatever as regards the dimensions of the working parts. Whilst one maker employs bearings six diameters long, another is content with four diameters; in one machine the bearing next to the pulley is of the same size as that next to the commutator, and in another machine the latter is smaller, and discrepancies of 20 to 30 per cent. in the sizes of spindles are by no means uncommon. It is, of course, not always possible to dimension working parts to the fraction of an inch; existing patterns have to be used in, and it will often pay to make a spindle stouter or a bearing longer than necessary in order to avoid too great a multiplication of standard sizes, and so reduce shop expenses. The variations which occur in similar machines of different makers are, however, far too great to be accounted for by such reasons, and the true explanation will probably be found in the fact that electrical engineering has not yet shaken itself into generally accepted grooves, and each maker goes his way without troubling himself much about the mechanical strength of his machines until a breakdown occurs, which reminds him that this or that part is too weak. Then the particular part is increased in all the machines, and so the process of evolution goes on producing the heterogeneous result above alluded to. In other branches of engineering there is much greater uniformity of sizes. If we inspect half a dozen portable engines of the best makers, we shall find almost identical dimensions of cylinder, piston rod, cross head pin, crank pin, crank shaft, bearings, &c., and even the grate and heating surfaces will be found the same within a few per cent. But then portable engine making is a much older trade than dynamo making, and with time the anomalies and vagaries of design in the younger trade will no doubt also vanish.

One of these anomalies which deserves special mention is the size of dynamo pulleys. The size of a belt and corresponding pulley to transmit a given power at a certain speed can be calculated to a nicety, and even an ordinary millwright would never dream of putting a pulley on a shaft without having first ascertained, either from previous experience or from calculation, what size to make it so that the requisite power can be safely transmitted. We doubt whether the highly scientific dynamo maker does the same. He puts on a pulley which he thinks will "about do," and if the machines gets on the job, and it is found that with the original pulley the required speed cannot be obtained, the remedy is simply the putting on of a smaller pulley regardless of the possible dangers of overstrained belts, bent spindles or hot bearings. For the benefit of our younger readers we shall in this article discuss the question of dynamo pulleys, so that they may learn how to avoid such mistakes.

The power which can be safely transmitted by a belt depends on the permissible working stress in the belt, its speed, the coefficient of friction between belt and pulley, and the arc spanned by the belt. The pull transmitted is the difference in the stress between the driving and slack side of the belt. Let T_1 represent the former and T_2 the latter in lb., then the pull P at the circumference of the pulley is

$$P = T_1 - T_2.$$

At a belt speed of s feet per minute the transmitted power is

$$H.P. = \frac{(T_1 - T_2)s}{33,000}.$$

The belt speed with a pulley d inches in diameter and running at n revolutions per minute is

$$s = \frac{\pi d n}{12}.$$

If, therefore, we know the size of pulley, the revolutions per minute and the horse power, we can calculate the pull transmitted, and to find the dimensions of the belt, we must determine the relation between this pull and the working stresses in the two sides of the belt. Let f be the co-efficient of friction between belt and pulley and a the ratio of the arc spanned by the pulley to its circumference, then the ratio τ between the working stresses in the tight and slack side of the belt is

$$\tau = \frac{T_1}{T_2} = e^{2\pi fa}$$

where $e = 2.71828$, the base of Napierian logarithms. It will not be necessary in this place to demonstrate the above formula for τ , as it can be found in any text book on applied mechanics.

Our object is to show how the sizes of belts and pulleys for any given dynamo can be calculated, and for practical use we append a table by means of which the size of pulley and width and thickness of belt for any power can be found almost at a glance, but in reducing the problem to this very simple form it is of course necessary to sacrifice the general applicability of the formulae by assuming certain conditions which should as far as possible represent the majority of cases arising in practice. These conditions are

1st, the arc spanned by the belt; 2nd, the co-efficient of friction; and, 3rd, the safe working load per square inch of belt section.

As regards the first condition it should be borne in mind that dynamos are generally speeded faster than the machines to which they are belted. The pulley on the dynamo is therefore smaller than the rigger on the counter shaft or the fly-wheel of the engine from which it is driven, and the arc spanned by the belt on the dynamo pulley must be less than π (180 deg.). How much less will depend on the distance of centres and the dimensions of the pulleys; also on the position of the tight side of the belt. If the tight side in a horizontal transmission is above, and the slack side below, the arc spanned will be less than with the opposite arrangement, and to get a maximum of "grip" with a minimum of strain in the belt and on the dynamo spindle the dynamo should be put down in such way that the slack side of the belt comes uppermost. In this case, even with very short centres, the arc spanned on the dynamo pulley will be greater than $0.4 \times 2\pi$, but in order to include cases where local conditions render this arrangement impracticable, we shall assume that $a = 0.4$, that is to say, that the belt spans forty per cent of the total circumference of the pulley.

The next point to settle is the co-efficient of friction f ; and here we are met by the difficulty that the authorities widely disagree. We find from Rankine's Mechanical Text Book that the co-efficient between leather and metals varies from .15 to .36, according to the condition of the surfaces and lubrication; and in his Rules and Tables, page 241, he recommends that calculations of driving-belts should be made on the supposition that the surfaces are oily, when it will not be safe to assume more than .15 for the co-efficient of friction. In his "Machinery and Millwork," page 352, we find, however, that, in view of the experiments of Messrs. Towne and Briggs, the author rejects Reuleaux's co-efficiency of .25, and recommends .42 as safe in all cases where reasonable care is taken to keep the belts dry. Weisbach gives $f = .28$ for turned cast-iron pulleys with a polished and greasy surface; and Unwin, in his "Elements of Machine Design," page 311, recommends for ordinary cases a co-efficient lying between .3 and .4. Where authorities differ to such an extent, the practical engineer is left very much to his own judgment as to which of the values of f he will adopt in his general practice. The writer from his own experience has found that a co-efficient of .3 is safe, and this value will therefore be taken in the following calculation:—

Having settled the length of arc spanned and the co-

* See page 78 (Jan. 27) for previous article on this subject.

of friction we can determine the ratio between the stress in the tight and slack side of the belt when at work.

$$T_1 = 2 \times 0.12 = 2.125.$$

Stress in the tight side is therefore a little more than that in the slack side, and the pull transmitted is

$$P = .53 T_1.$$

We can find the section of belt required to stand the T_1 , we have yet to settle the third of the conditions mentioned above, viz., the safe working load. Here again considerable variance in the figures given in text.

Morin recommends a working load of .2 kilos. per millimeter, or say 285lb. per square inch; the book of the German Engineers' Society "Hütte" recommends .1 to .125 kilos., or say 175lb. per square inch. Leloutre (Resumé de la Société des Ingénieurs, December, 1878, page 315), recommends a working load as high as 700lb. per square inch (on the ground that strained to this point is not liable to stretch any more), whilst Unwin fixes the working load at 320lb. accepting any one of these widely different figures, it is useful to inquire what regulates the acceptance of particular working load. This must evidently depend on the ultimate breaking strength of the belt and the factor by which we may choose to employ. The ultimate strength of leather used for belting varies, according to Unwin, from 3,000lb. and 5,000lb.; whilst Rankine gives it as 4,000lb. for the solid parts of the belt, and 2,400lb. for the laced joints. The laced joints will break when the load is 1,300lb. per square inch of the solid part. Now, as dynamo driving is concerned, laced joints may be regarded as a thing of the past. They are objectionable not because of their weakness, but also because the joint being over the dynamo pulley produces sometimes a jerk in the movement of the armature, and a corresponding flicker in the lights. The great convenience of laced joints is that the belt can easily be tightened when it has become slack from stretching, but as dynamos are nearly always provided with sliding bed and timing gear, a cemented or riveted belt is equally convenient. This consideration also disposes of M. Leloutre's remark regarding the loading of belts beyond the stretch limit above mentioned. In determining the size of a belt, must, obviously, base our calculations on the strength of the riveted joint, that is, take 2,400 as the breaking load, but even this figure is too high, because it was determined with a steadily increasing load, whereas, in actual use, every part of the belt is subjected to continual variation of strain as it passes from the tight to the slack side, and back again to the tight side. These variations occur many times per minute, and it is well known that all materials become fatigued under varying strains, and break under a smaller ultimate load than would have been the case had the load been constant. According to Leloutre the breaking stress of belts is 4,300 lbs. with a constant load, and 2,800lb. with a variable load. The fatigue value is therefore the ultimate load to 65 per cent. of its value, and applying this to riveted joints we can calculate their ultimate strength as 1,560lb. With a factor of safety equal to 4lb. this corresponds to a working load of 390lb., and with a factor of 5 to a working load of 350lb.

Since the strain resulting from bending (and which is neglected in the above calculation) is somewhat greater for double belts than for single belts, we adopt a factor of 5 for the former and 4 for the latter, so that the sectional area for double belts (from 1/2 in. to 3/4 in. thick) must be calculated for a working load of 310lb. per square inch, and that for single belts (1/4 in. to 3/4 in. thick) for a working load of 350lb. per square inch.

The above formula giving the relation between the stress in the driving side of the belt and the pull transmitted to the pulley, no account has been taken of the effect of centrifugal force. In slow speed machinery this is trifling, but with high-speed machines, such as turbines, it may sometimes become necessary to take centrifugal force into account. The effect of this force is a tendency to lift each particle of belt, as it travels round the pulley, off its surface, and thus to diminish the grip and the transmissible with a given working stress. To counteract this tendency, it is necessary to put the belt on

tighter to begin with; and this must obviously increase T_1 , as compared with the stress which would suffice did centrifugal force not interfere. It would be outside the scope of this article, which aims at giving a few simple data for practical use, were we to investigate mathematically all the conditions under which the belt works; it must therefore suffice to state without giving the mathematical proof that the increase of stress occasioned by centrifugal force can be found as follows. Imagine a piece of the belt, of length equal to the radius of the pulley, cut off and weighed. Let this weight, W , be concentrated in one point at the circumference of the pulley, and find the corresponding centrifugal force by the formula

$$F = .000344 W \frac{d^2}{2} n^2,$$

then F represents the force in lbs. which must be added to the theoretical load T_1 to obtain the total working stress in the driving side of the belt. To estimate the importance or otherwise of this correction we shall take as an example the case of a 12in. pulley running at 1,000 revolutions with an 8in. belt 1/4 in. thick. The specific gravity of leather is very nearly that of water, and is generally taken as 60lb. per cubic foot. A piece of this belt 6in. long will therefore weigh 83lb. The centrifugal force is

$$F = .000344 \times 83 \times 0.5 \times 1000^2 = 143lb.,$$

which, distributed over a belt area of 4 square inches, increases the theoretical load by only 36lb., or less than 12 per cent. of the working load. Now it is evident that we must allow some margin in the tightness with which the belt is originally put on, for the simple reason that this work must be left to the judgment or mechanical instinct of the attendant, and as it will hardly be safe to allow a smaller margin than 25 per cent. on this account, ample allowance is thereby also made for the influence of centrifugal forces. In our previous article it was pointed out that a dynamo, to be mechanically perfect, must be able to stand an occasional short circuit, but only for a very short time. Now, where the dynamo is driven from its own engine, a short circuit will pull the engine up before the excessive current has had time to dangerously heat the machine; but where the dynamo is driven by belt from a main shaft, which may be receiving motion from a large engine the power of which is much in excess of that of the dynamo, a short circuit will not pull the engine up; and to save the dynamo from overheating it is very desirable that in such a case the belt should come off. For this reason the margin of belt-power should not be too great, and in the following table we have adopted 25 per cent. as a sufficient allowance for injudicious tightening, whilst at the same time the allowance is sufficiently small to cause the belt to break or to fly off if the machine be short-circuited:—

PULLEYS FOR DYNAMO MACHINES.

Diam. inches.	Width of Belt. 1/4 in. thick	Area. Square in.	Working Stress lb.	Transmittal Pull lb.	Horsepower* at 1,000 Rev.
6	5	1.00	350	140	6.5
7	5	1.25	437	175	10
8	6	1.50	525	210	13.5
8	4	2.00	525	248	16
9	7	1.75	613	245	17.5
9	5	2.50	775	310	22
10	5	2.00	700	280	22
10	6	3.00	930	372	29.5
12	7	3.50	1,081	433	41.5
15	8	4.00	1,240	495	59
18	10	5.00	1,550	620	88
24	12	6.00	1,860	742	141
30	14	7.00	2,170	865	205

*The horse-powers are given to nearest decimal.

The use of this table will best be explained by one or two examples. Say we have a dynamo running at 1,500 revolutions and absorbing 20 h.p. What pulley and belt will be required? Reduce power in accordance with speed from 20 to 20 $\times \frac{1,000}{1,500} = 13.4$. The nearest number in the horse power column occurs in the third line, viz., 13.5, and the corresponding pulley is 8in. diameter, and

should be about 7in. wide to take a 6in. single belt, $\frac{1}{2}$ in. thick. If the belt is of a different thickness, the width may be altered so as to keep the cross sectional area 1.5 square inches, as given in the table. Should a different diameter of pulley be desirable, the area of belt must be changed inversely. As a second example, assume that we want to know the pulley to be used with a dynamo absorbing 60 h.p., and running at 400 revolutions. Increase power in accordance with speed from 60 to 600.

$$\frac{1,000}{400} = 150 \text{ h.p.,}$$

and find the nearest number in the table, which is 141. The pulley will be 24in. in diameter, and the belt

$$12 \cdot \frac{150}{141} = 12.8, \text{ or say } 13\text{in. wide, if its thickness be half an}$$

inch. The table can also be used to find the power which can be transmitted with any given pulley and belt, but as these applications are obvious, we need not describe them at length.

PRACTICAL ELECTRICAL UNITS.

BY W. B. EESON.

(Continued from page 222.)

16. Electrical Return. In estimating the energy actually returned at the terminals of the dynamo at 70 per cent. of the horse power indicated in the cylinders, it is assumed that the engine drives on to countershafting from which the several dynamos are driven. In the Victoria Station installation, when tested some years ago, it was found that 65 per cent. of the I. H. P. was returned at the terminals. But since then considerable improvements have been made, not only in the dynamos themselves, but in the methods of laying down large installations. In July, 1886, there were published in *Industria* the results of several determinations made by Messrs. Paterson and Cooper, on their machines driven by Gwynne's engines, and the mean of the experiments showed that 71.3 per cent. of the I. H. P. was returned at the machine terminals in the form of electrical energy. Later, in the same year, the results obtained by Dr. Hopkinson in testing the Tilbury Docks installation were published in *The Electrician*. This installation was erected by Messrs. Crompton, and there was obtained in the circuits a useful return of from 70 to 72 per cent. of the I. H. P. It is most probable that the eighteen months which have elapsed since then have brought us a still higher return.

The above results apply to cases in which the dynamos are driven through countershafting, and the work expended in overcoming the friction of countershafting is very considerable. When the employment of the latter is indispensable the engines and dynamos ought, if possible to be on opposite sides of the shaft, in which case the pressure on the bearings becomes very much smaller than when both engines and dynamos are on the same side. But unfortunately the arrangement is generally the other way, and when countershafting is used it absorbs in consequence a large percentage of the total power. The direct belting of the dynamos to the engines has considerable advantages, and this method may be expected to come largely into use in time. Instead of driving a number of dynamos from one large engine the tendency is to divide up the power, driving only one or two machines from smaller engines. When two are driven a flywheel pulley is keyed on each end of the crank shaft, a machine being belted from each. Though the percentage obtained with directly belted dynamos is necessarily higher than with those driven through countershafting, the writer is not aware that any experiments have been published showing the return actually obtained.

It is still an open question whether better results are obtained with dynamos directly coupled to the engine crank shaft or with those directly belted. The directly driven machine must have a low speed, which, as regards efficiency, is bad in a dynamo; while the engine must have a high speed, bad *per se* in an engine. It seems that the best proportion between the speeds of prime mover and dynamo is obtained by the directly belted combination, though one is bound to confess that the chief objection to the directly coupled arrangement lies in the high price required for the dynamo, in order that for such low speed as is compatible

with engine durability its efficiency may be as high as a belted machine. There is a great number of directly coupled machines at work giving great satisfaction to the users, and they possess the advantage of taking up less room than when belt driving is adopted. As regards the return obtained there are no reliable data. A set of tests on a combination of Willans engine and Crompton dynamo belonging to the Vienna installation was published in April, 1886; but the tests were not conducted properly, and both I. H. P. and electrical horse-power varied during the trial run in a very extraordinary way. The tabulated results showed a return of from 66.5 to 79.8 per cent. Probably the true value lies between the two at 74 per cent., but it is hard to say. In a paper read at the Institution of Civil Engineers three weeks ago Mr. Willans claims to have obtained at his dynamo terminals the high return of 82.3 per cent. of the I. H. P. The detailed figures of the test have not yet been published.

17. Dynamo and Engine Trials.—In making tests of the kind above described the fulfilment of several conditions is important if trustworthy results are to be obtained. In the first place the electrical load must be constant during the whole time of the trial. In the absence of the lamps the circuit may consist of large resistance frames, or better still of a water resistance, which is very easy to manage. In the latter the plates forming the electrodes are movable, and can be adjusted to any distance apart. The engine should be run with the stop valve full open, the period of admission, &c., being regulated by the expansion gear. If it is only desired to establish the relation between the energy obtained from the dynamo and the I. H. P., simultaneous indications of the engine and observations of the measuring instruments are all that are required, and the duration of the trial need not exceed the time required to take half-a-dozen sets of readings. Diagrams from the two ends of the cylinder necessarily take some time to draw, and it is absolutely essential that during the time so occupied, the speeds remain constant. It is very easy to fulfil this condition if the load is constant and everything in fine running order, in fact there is no reason, under such circumstances, for any variation in speed. Speed indicators, attached to both dynamos and engines, should be watched while the diagrams are being taken. If, due to any cause, variations occur, that set of readings should be canceled. The speed indicators should, of course, be carefully checked by counters.

When a test run has to be made for the purpose of ascertaining the efficiency of the boilers and engines, it should extend over several hours, and the same conditions must be observed regarding constancy of load during the trial. The cost of electric lighting depends to a great extent on the amount of fuel consumed, and this is determined by the efficiencies of the boilers and engines, the former estimated according to the weight of water evaporated per pound of fuel consumed, and the latter by the I. H. P. which can be maintained for a certain weight of steam used per hour, and by the ratio of the power delivered at the crank shaft to that indicated in the cylinders. The efficiency of the whole system thus depends on the electrical power obtained at one end of a series of energy transformations for the coal and water furnished at the other end. In starting a plant for the first time it is necessary to have a good preliminary run before the actual trial commences, not only for the purpose of getting the machinery into proper working trim, but in order that the whole of the operations may be properly equilibrated. It is necessary that there be supplied to the boiler just coal and water enough to give the required electrical power—no more, no less—and it is only by actual trial that these can be determined. It is fatal to the success of the trial to work by fits and starts, and results obtained under such conditions are quite untrustworthy. If the trial were run without preliminary adjustment and the boilers turned out to be rather large for their work, probably for half the run part of the steam would be blowing into the air through the safety valves. On the other hand, if the boilers were too small the steam would go down, disturbing the equilibrium of the system, and assuming the possibility of getting the steam up again this could only be realized by hard and consequently wasteful firing. In the latter case the electrical load must be reduced until the steaming capacity of

ers is reached, when the trial run can proceed with firing in perfect balance. With some of the rapid stoking boilers now in use stoking becomes something of an art, and not one stoker out of ten, unless used to boiler, can undertake the job of keeping the steam right pressure without allowing it to blow through pipes, or the water to rise or fall in his gauge glass. Stokers have a good deal in their power, and can easily make the coal bill high or low. Having ascertained the exact amount of fuel and feed water required to run the engines at uniform speed with the load fixed the trial commences. While it continues the steam pressure must be kept uniform and the water supply regulated, so that throughout the run it stands at the same height in the gauge glass. It is preferable for the trial to be a continuation of the preliminary run towards the end of the latter everything is in condition. The run must not be continued till the boiler is full; but the fires must be in the same condition as when the measurements cease as when they were started. At the end of the run the coal must be weighed and the water supply measured. Indicator diagrams should be taken at intervals of ten minutes, and observations of the current, voltage of potential, and speeds, simultaneously made and properly tabulated. If the trial run takes place on a day to the preliminary, it may be necessary to run for an hour or so before taking readings, in order that the engine may be got into normal working conditions. The time spent in getting up steam, and the time it is possible to run at full load after ceasing to add fresh fuel, should be noted separately.

Trials may be objected to on the grounds that the results here laid down never obtain in practice. It is true that in practical working such care is the exception, but there is no reason why it should be so. More than that, until the objector tells us how bad we are to make it, until he specifies exactly the degree of carelessness we are to adopt in our work, we are justified in showing what carefulness can do, and in turning out the best possible.

(To be continued.)

CHELTENHAM

We have already referred, in our issues of the 16th and 23rd, to the work energetically initiated and pushed forward by the Lighting Committee of the Taunton Town Council, and by Mr. H. G. Massingham, the managing agent of the local electric lighting Company. Recently a deputation from Cheltenham paid a visit of inspection to the installation carried out by the Company in question, to abstract the report made: Though maintained in the best order, the central station of the Taunton Company is somewhat confined space at the back of Mr. Massingham's premises. Originally it was designed only to supply the light to his shop and to a few adjoining houses; but it has gradually developed as the area of supply has extended, and especially since the contract has been let for lighting the public streets. The power is obtained from two semi-portable boilers, working to a pressure of 100 lb. per inch, and driving two horizontal 35 h.p. engines, which operate a long transverse shafting to which the dynamos are attached. The dynamos are five in number, three of the Thomson-Houston pattern, and the others of the English agents of the Thomson-Houston Company, whose system the Taunton installation is carried out on. The arc and incandescent lamps are supplied, the latter being run solely through the medium of accumulators, the former running only in the evening when the arc lamps are out. The arc lamps are about 65 in number, 30 of which are rented by the Corporation, and the remainder by private customers. The incandescent lamps number about 100 and are supplied through four sets of accumulators, each consisting of 50 cells, equal to the supply of as many 16-candle lights for eight hours without re-charging. The three dynamos usually running at one time, one is reserved for private users, and the third charges the accumulators. The two reserve dynamos relieve the others at the will of the engineer in charge, but in case of necessity the service could be carried on for some time by two, or even one, of the dynamos, and easily by one of the two engines. From the central station the visitors were conducted to an inspection of one of the sets of accumulators placed in an upstairs room of Mr. Massingham's large premises, and then they passed into the street, and went over the area of the public lighting service. This comprises the principal part of the town—almost the whole of the business portion—of the town, within a half-mile radius of the works. The lamps, as already stated, are thirty in number, and average 100 yards apart. They are placed on standards, about twenty-five feet high, the lower part, to a height of five feet, being of iron, and the upper part of wood. These standards, though not positively unsightly, have not had appearance much studied in their construction, their cost having only been £3 a piece. The wires are usually carried overhead from lamp to lamp direct, the old iron gas standards, elongated for the purpose, being used as intermediate supports. This suggests, as is the fact, that in the streets lighted by electricity, the use of gas has been entirely discarded, and the confidence thus shown by the Corporation in the new illuminant has not, during the twenty months that have elapsed since its adoption, been for one moment misplaced. Along a considerable length of the streets the wires are run on posts over the roofs of the houses, and this—as regards appearance, at least in the daytime—is certainly the preferable plan. Only in a very short section are the wires taken underground, a method of conveying them which entails risk from faults of insulation to which electricians attribute the partial failure of the service at Leamington.

The committee afterwards visited two or three of the business premises lighted by electricity. The result was very satisfactory, the visitors being particularly struck by the efficient manner in which arc lamps had been utilised for interior lighting. In the street lighting the distance between the lamps varies from 80 to 150 yards, the standards being placed, when practicable, at the junctions with side streets. At any point midway between two lamps it was found that moderately-sized print could be read. The Corporation are negotiating for a considerable extension of the public lighting, and the electric light will no doubt be ultimately employed in all the thoroughfares of the town.

THE UNION BANK OF LONDON.

The head offices of all the principal banks are gradually being fitted with the electric light. This illuminant is better adapted for such lighting than any other with which we are acquainted. Indeed, this must be true in all cases where large numbers of employees are congregated together in the usually not too well ventilated rooms of ordinary London buildings. The head office of the Union Bank in Prince's-street is a modern building, hence could from the first be fitted with what we must still call the new light. The fittings throughout have been carried out by Messrs. B. Verity and Sons, of King-street, Covent Garden, under the supervision and from the designs of Messrs. Drake and Gorham, who are acting as engineers on behalf of the board. A few days ago we visited this installation, the plant for which is fixed in the basement, and consists of two 9 h.p. Otto engines, driving two Elwell-Parker latest invented B-type 12-unit dynamos. Fig. 1 (see next page) illustrates these engines, and we are informed that they have run admirably from the first till now.

The dynamos run at 750 revolutions, and are fitted with heavy flywheels, to prevent any flickering of the lights. An accumulator battery of 106 Elwell-Parker, of 23 L-type cells in glass boxes, is used in conjunction with the machines. This battery supplies a part of the current during the time when most lamps are on, and furnishes current after the engines stop running. Distributing switch boards, fitted with Drake and Gorham's patent ring contact switches, are used for controlling the various branch and main circuits. The wiring is carried out with a number of small circuits so arranged that should any failure occur to half the

generating plant every alternate lamp only will be effected. This arrangement also enables all the fuses to be placed in the engine room where they are readily accessible. The fittings have been specially designed for office work, and every desk standard has both gas and incandescent lamps, the jets projecting on either side of the incandescent lamp, and forming a support for the shade. The total number of lamps fixed is 330, most of which are half-frosted, either at the cap or point end, to suit pendants or standards. This method of toning the brilliancy of the filament is more economical than lamps frosted completely,

shown in the left hand corner. The stairs lead to the accumulator loft.

Two of Messrs. Drake and Gorham's Excess Indicator are fixed in connection with the batteries to give warning when the normal rate of discharge is reached, and there is also a special arrangement of cut out for the night so that in the event of an excessive number of lights being used for cleaning purposes after the offices are closed, the circuit is broken, and can only be replaced when the number of lamps has been reduced to the normal. This is arranged that it is impossible for it to be wedged out

THE UNION BANK OF LONDON INSTALLATION.

FIG. 1.- Nine Horse Power "Otto" Gas Engine, by Crossley

as only the portion of the lamp in the line of the eye is obscured, the remainder reflecting its full light on the desks. A modified pattern of the Edison screw lamp holder with tap is employed throughout, and each lamp is provided with the well known Edison pattern screw safety fuse. By means of terminal boards either dynamo can be connected to either battery, and the lighting circuits can be interchanged in a similar manner.

We illustrate on page 324 a plan of the arrangements in the engine room, except that we do not show the four water tanks. The terminal boards, instruments, &c., are

shown in the left hand corner. The stairs lead to the accumulator loft. The designs for the silencing arrangements in connection with the engines is found to answer admirably, and there has not been the slightest complaint of noise or vibration either from the bank officials or others in the neighbourhood.

The ventilation of the engine room is effected by means of a Blackman air propeller, coupled direct to a one horse power Elwell-Parker motor, the speed of which can be varied as required according to the temperature of the room.

CORRESPONDENCE.

CATALOGUE PIRACY.

THE EDITOR OF THE ELECTRICAL ENGINEER.

Messrs. W. T. Glover and Co. call attention in issue to the copying of their catalogue by other and suggest that some other parts of the same are not as original as they might be.

Following may be one of the curious coincidences frequent enough in literature, or may illustrate a case of catalogue manufacture. It is a sample only.

Magnet cores are the best Norway thoroughly annealed and as nearly as possible free from the presence of permanent magnetism. Magnets are wound with wire having 96 to 99 per cent. of the conductivity of pure copper.

Make our own wire and put thorough man-

ner to use mahoe the bases of our instruments, for the reason that it takes a high polish, and especially because it is liable of all the odds to warp or

be remarked that the preference for teak does not find the preface. In the descriptions of the different instruments it will be found that the bases are made of mahoe, as in the originals, the illustrations of which are fully reproduced. These originals account for the error of pages 33 to 62, 74 to 79, 88 and 89.

Drawing attention to the above coincidences it should be remembered, that it is a not unusual practice for makers to supply blocks and descriptions for insertion in catalogues of those who do not make, but may be of the above may be open to such an explanation, but take up your space by discussing the ethics of the matter, but would simply remark that Messrs Glover considered somewhat unreasonable in complaining of sincere flattery as the complete imitation of their catalogues.—Yours, &c., J. E. KINGSBURY.
 April, 1888.

TELEPHONIC LITIGATION.

THE EDITOR OF THE ELECTRICAL ENGINEER.

A certain dealer in electromagnetic telephones in the newspaper reports of the recent case, "The Telephone Company v. the Equitable Telephone Association," as a means of pushing their business, pointing out their instruments employ no carbon, while it is the transmitters of the Equitable Telephone Association which are specially attacked, it is well that the public be informed that these said newspaper reports are as false as is frequent when the daily papers attempt to discuss scientific matters, calculated to give very erroneous impressions.

As a matter of fact, the United Telephone Company are the receivers used by the Equitable Telephone Association quite as much as the transmitter, and, if their case can be upheld, all the "membrane" telephones in the market are equally infringements.—Yours, &c.,

A. A. CAMPBELL SWINTON.

10 Victoria-street, E.C., April 3.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR: It is whispered that the proposed new rules of the Society of Telegraph Engineers and Electricians relating to electric light installations may not be materially different from those of the Phoenix Fire Office. If so, what good purpose can their promulgation serve?

Moreover, the Phoenix rules are *copyright*, and there may be something to say on that score presently.

Will anything be gained by attempting to establish a kind of dual control? On the contrary, will not the beneficial effect of the moral sway hitherto exerted be seriously weakened or altogether destroyed? There has been a certain safeguard to the public in the fact that contractors have generally evinced a readiness to conform to the Phoenix rules, and, as a natural consequence, the class of work has been steadily improving, and the "cutting" firms have been finding it increasingly difficult to oust the truly conscientious contractors. If users of the light discover that there is need (real or imaginary) of a rival set of regulations, the growing confidence in this branch of electrical engineering will be shaken. If there be any necessity for revision, or for extending the scope of the Phoenix rules, would it not have been possible to arrange a meeting of *representative electrical contractors* (upon whom the due execution of important works must fall, and not, I say it with all respect, upon the *consulting electricians*), at which Mr. Musgrave Heaphy, whose enthusiasm is admitted, and to whom belongs the credit of compiling the Phoenix rules and bringing them in successive editions to their now complete form, might be present, and conclusions arrived at satisfactory to all parties concerned?

It is to be hoped that the members of the profession will insist that an independent committee be appointed by the Society to investigate and report upon the facts of this unfortunate dissension, and that such committee may invite Mr. Heaphy to give evidence and produce any correspondence that may have passed between himself and the Council of the Society on the subject, which is one of the utmost importance and merits careful investigation.

It is, perhaps, a question whether the Council possesses the right to act in this matter without consulting the main body of members of the Society, and one thing is certain, viz., that scarcely a month will ever pass without the point involved being raised in some form or other, so that a settlement ought to be effected forthwith.

What we really need now is an efficient leader, and anyone possessing the requisite qualities who will come forward at this juncture will earn the lasting gratitude of the whole profession.—Yours, &c.,
 CONTRACTOR.

Probably Electrical.—The following curious phenomenon, described by M. A. Lalancé, would appear to require as the essential condition of its production a very dry atmosphere, such as that which sometimes prevails in Russia and Canada, a fact which points to the probability of an electrical causation. "On returning to my room on one occasion," says M. Lalancé, "I found it full of thick black smoke. This smoke was due to two argand lamps which had been flaring. I opened one of the casements and went out for one hour, after which I was able to go to bed. Next morning I expected to find my papers and furniture in a terrible state, but to my great astonishment nothing was soiled. In the centre of the room, I observed on the carpet, a perfectly round ball from 3 to 4 centimetres in diameter, having the consistency of cigar ash. I found some other balls, but smaller and less perfect—that is to say, flattened to some extent at certain portions of the surface. In the angles of the room there was a small quantity of black dust. There was about 20deg. of frost outside, and the room was heated to about 20deg. centigrade." (This was in Russia: the temperatures in Fahrenheit degrees were about —4 and 68.) M. Lalancé, who thinks that the phenomenon might be due to a difference of external and internal temperatures, and independent of absolute temperature, offers, in the *Journal du Ciel*, to supply any further particulars which might enable investigators to obtain a repetition of the phenomenon.

PLAN OF ENGINE ROOM.—UNION BANK INSTALLATION.

(For details see page 321.)

T.B. Nos. 1 and 2 show Terminal Boards; S.B. Nos. 1 and 2 show Switch Boards.
Exhaust Pipes Nos. 1 and 2 with wrought iron checkered plates; otherwise the plan explains itself.

THE ELECTRICAL ENGINEER.

Published every Friday.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at **THREE WORDS for ONE PENNY**, with a **MINIMUM** charge of **SIXPENCE**.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., who was in his scientific prime at the beginning of the century. This will be followed by SIR HUMPHREY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

PROMOTERS' TACTICS.

The wisdom of the serpent, if not the harmlessness of the dove, dwelleth in those City offices devoted to the promotion of companies. Scarcely a week passes but our City Notes record the registration of one or more companies. And in due time these fledglings are sent out into the world to gather unto themselves many feathers in the shape of capital. It stands to reason that many of these companies are formed for quite legitimate objects, and yet the method of procedure in the promotion of such companies is often open to severe censure. One sentence reveals the real drift of the minds of the promoters, and it appears in almost every prospectus, to the effect that a quotation on the Stock Exchange will be asked for. Now the company that is really promoted for business purposes is altogether different from that promoted for speculative purposes, and both differ from the company where a substratum of business is intended to hide the real intention of Stock Exchange transactions. Our remarks are intended to apply solely and wholly to companies of an electrical character, manufacturing or distributing, and our grave objection to the tactics of the promoters is due to their care in so launching the company that the technical journals really conversant with the matters involved are unable to give a word of warning or a word of support. The prospectus is issued after these papers are gone to press in the one week, and the list is, if possible, closed before they go to press the next week. That is the rule, to which, however, there are a few exceptions. Such procedure immediately stamps the transaction as simply and purely speculative. It is the technically ignorant who are asked to subscribe, for, as we say, few of these prospectuses ever appear in the advertising columns of the technical paper. Testimonials—clear as noonday to the initiated—are used to influence those whose knowledge is confined to names, and not to scientific language or terms; and such persons are wholly unable to limit the purport of such documents to their intrinsic meaning. Frequently their real signification to investors is don't, don't, don't; and yet such testimonials form the principal paraphernalia of the promoter to induce subscription. Few things are as certain in electrical matters as that there is a screw loose somewhere in those undertakings which seek to avoid comment in the technical papers. Quite recently a large company has been floated, which is an offender in the direction we have already mentioned, and in others we are about to name. The patents bought and sold in this case have a certain small value, say, about one-twentieth of what has been paid, or is to be paid. The article is not an expensive one to manufacture, nor is it of great superiority to similar articles in the market. Put into the hands of a manufacturer, who would perhaps invest a few thousand pounds in pushing the

article, it would bring a fair but not an exorbitant return. As it is, the promoters no doubt hope to make a lot of money by selling foreign patents, hence they ask for thousands where tens would be amply sufficient. The whole affair is a gigantic gamble, and game of brag. The subscription is not derived from men who care one iota about business—their whole concern is quotation on the Stock Exchange. A market is somehow made with the jobbers, shares are dealt with at a premium before allotment, and the speculators, hoping to benefit in the rise and fall, are tempted to take a plunge. It is not business, it is pure gambling. The company we specially refer to is the Schauschleff Company, for a primary battery, with a capital of £200,000, of which £120,000 goes to the vendors, £30,000 is for working capital, and £50,000 is at present not issued. The prospectus says somebody has offered £40,000 for the Australian patents, or is to forfeit £2,000. Well, the forfeit should be paid, and even then the case will be one supporting the old adage that "a fool and his money are soon parted." The price given for this battery is out of all proportion to its value, and although we may agree with every word the experts have said in their testimonials, we contend that the statements made do not warrant any electrician venturing one share in the concern from a business point of view. Fancy—with £30,000 working capital—a nett return of £7,500 must be obtained to pay a 5 per cent. dividend. We again say we have every reason to believe that a good business could be made with this battery, but the enormous capital almost entirely vitiates any prospect of success. It is only a few days ago since Mr. Watt was showing specimens of pure zinc obtained by a process he has patented. Have the promoters of this Company thought of the effect the production of pure zinc will have in the construction of almost all primary batteries? Amalgamation will not be required; it will be a thing of the past, and therefore any patent depending upon amalgamation for its value will lose its all.

The tactics of the promoters in this, as in other cases, have been eminently successful. All that can be said by those who know the value of a primary battery is useless to warn investors that even such a battery may be dear at a price. One more company is added to the long list of ventures floated in such a manner as to strangle their business success at birth, and this is all the more deplorable in that the company really possesses a good and, in many respects, an excellent battery.

THE GREAT TELEPHONE CASE.

We have received from our namesake across the Atlantic a verbatim report of the decision in what may be termed the great telephone case of America. The decision related to no less than six appeals be-

fore the Supreme Court of the United States, in each of which the American Bell Telephone Company was on the one side, and Professor Dolbear, the Molecular Telephone Company, the Clay Commercial Telephone Company, the People's Telephone Company, and the Overland Telephone Company respectively, were on the other side, there being one cross appeal, making the six cases. The result is throughout in favour of the Bell Telephone Company. The decision, for example, supported a sufficiency of the specification. It says:—

"The law does not require that a discoverer or inventor, in order to get a patent for a process, must have succeeded in bringing the art to the highest degree of perfection. It is enough if he describes the method with sufficient clearness and precision to enable those skilled in the matter to understand exactly what the process is, and if he points out some practicable way of putting it in operation. This Bell did. He described clearly and distinctly his process of transmitting speech telegraphically by creating changes in the intensity of a continuous current or flow of electricity in a closed circuit, exactly analogous to changes of density in the air occasioned by the undulatory motion given to it by the human voice in speaking. He then pointed out two ways in which this might be done, one, by the vibration or motion of bodies capable of inductive action or by the vibration of the conducting wire itself in the neighbourhood of such bodies; and the other by alternately increasing and diminishing the resistance of the circuit or by alternately increasing and diminishing the power of the battery. He then states that he prefers to employ for his purpose an electro-magnet having a coil on one of its legs, and he describes the construction of the particular apparatus, shown in the patent as Figure 7, in which the electro-magnet or magneto method was employed. This was the apparatus which he himself used without entirely satisfactory results, but which Professor Cross, Mr. Watson, Doctor Blake, Mr. Pope, and others, testify has done and will do what was claimed for it, transmit speech successfully, but not as well indeed as another constructed upon the principle of the microphone or variable resistance method."

Part of the decision will no doubt be contested by Prof. Silvanus Thompson who, as is well known, is strongly in favour of Reis's claims, but this decision maintains that Bell's method is not in Reis's apparatus. The decision says:—

"It was left for Bell to discover that the failure was due not to workmanship, but to the principle which was adopted as the basis of what was to be done. He found that what he called the intermittent current, one caused by alternately opening and closing the circuit, could not be made, under any circumstances, to reproduce the delicate forms of the

air vibrations caused by the human voice in articulate speech; but that the true way was to operate on an unbroken current, by increasing and diminishing its intensity. This he called a vibratory or undulatory current, not because the current was supposed to actually take that form, but because that language expressed with sufficient accuracy his idea of a current which was subjected to gradual changes of intensity, exactly analogous to the changes of density in the air occasioned by its vibrations. Such was his discovery, and it was new. Reis never thought of it, and he failed to transmit speech telegraphically. Bell did, and he succeeded. Under such circumstances it is impossible to hold that what Reis did was an anticipation of the discoveries of Bell. To follow Reis is to fail, but to follow Bell is to succeed. The difference between the two is just the difference between failure and success. If Reis had kept on he might have found out the way to succeed; but he stopped and failed. Bell took up the work and carried it on to a successful issue."

Similarly the decision deals with other anticipations, but it will be found that Mr. Justice Bradley, Mr. Justice Field and Mr. Justice Harlan were not able to concur with the other members of the Court in the result, so far as the question of Drawbaugh's invention was concerned.

UNDERGROUND CONDUCTORS FOR ELECTRIC CURRENTS.*

BY J. M. SMITH.

The question of underground conductors of electric currents is one which every person interested in electricity should study fairly and with a predetermination of solving. It is not purely an electrical question, in fact the electrical part of it is far overbalanced by the mechanical. There is no difficulty in finding an excellent insulating material, but the difficulty lies in the holding of this insulator on the conductor. Many substances are good insulators in dry places; some are good under water, some in damp places, and a few will stand acid and alkaline fumes and the ravages of sewer and illuminating gas, but how many will insulate under all these conditions, and in addition be substantial enough to withstand the mechanical injuries to which they are exposed when buried under the streets of our large cities? A few years ago wire wound around with a little cotton soaked in paraffin was thought sufficiently insulated until the insurance companies had a few losses, due, of course, to electricity, and then we had underwriter's wire. The name of this wire has sold hundreds of tons of it; but that does not prevent its grounding a whole system when it comes in contact with the least moisture. It, however, marks one state in the evolution of the perfect insulation. There seems to be comparatively little difficulty in making a cable that will carry high potential currents when constantly submerged. The conditions are substantially the same at all times. There are no alternate changes of moisture and dryness, no great changes of temperature, and very little of the destructive action of gases. The conditions of the underground conductor are very different. Here the conductor is dry, then wet; it is frozen, and again thawed; it is attacked by sewer gas, and the corroding action of the water leaching through the accumulated filth of the street, it is subject to the destructive action of the leaking gas and steam pipes, and finally, but not the less surely, to the ruthless "ditch digger." These are

certainly formidable obstacles, but a number of them have already been overcome, and the others must be. Public opinion says the wires of all kinds must go under ground, and electricians, engineers, and capitalists must find the means of doing it.

The question resolves itself into three parts. First. The electrical insulation of the conductor. Second. The protection of the insulator from the effects of moisture and corrosion. Third. The protection of both from mechanical injury.

The question of electrical insulation seems to me to be solved by at least six of the standard compounds now in daily use.

The second part of the question is the most serious. If any of the standard insulations can be enclosed so as to be protected from direct contact with moisture their chances of life are certainly improved; but if they can be hermetically sealed, they should be practically indestructible provided the casing is indestructible. We single out as among the best materials from which to form such a casing—iron and lead. Cast iron, underground, will last a great number of years, as shown by gas and water pipes, but it cannot be obtained in lengths much over 13ft., and the numerous joints multiply the chances of leakage. The conductors must of necessity be drawn into the pipe after it is in place. The conductor must be considerably smaller than the pipe, and therefore moisture will creep in between the two. Wrought-iron pipe, if well coated with asphalt or some similar substance, will last a long time. It may be had in longer lengths than the cast pipe, and the joints are more easily and surely made. If screw-threaded joints are used the conductors must be drawn in, with the same objections as with the cast pipes. If the lengths of pipe are prepared with the conductors in them before laying, joints must be made in the conductor, as well as in the casing, at short intervals. Joints are the bane of electrical construction. From the dynamo to the lamp and return the current is forced to pass joints which frequently offer more resistance than 1,000 feet of wire. At these joints the insulation, instead of being better than at other points of the conductor, is generally worse, and oftentimes none at all is found. It is not strange that the current should seek an easier path home, and take to ground, rather than be forced through the accumulated resistance of all these joints. I will venture to say that, of all the failures of underground conductors, 90 per cent. are directly traceable to the joints, and for that reason it is desirable to have as few as possible.

The conductor may be obtained in, practically, any length, and the insulation may be put on continuously; but in order to have a continuous casing it must be formed of some sort of ductile metal which can be closed about the insulated conductor in the course of its manufacture. Lead seems to be the only commercial metal that will find these conditions, and there are objections even to it. Lead is soft and easily punctured, and offers little resistance to crushing or bending, and is attacked by rats. On the other hand, the corrosive action of the earth has little effect upon it, while its pliable nature permits of its use in many places where iron pipes could not be used. Being soft and ductile it can be brought into such close contact with the insulation as to prevent, or at least retard, the creeping of moisture between the insulation and casing. It seems to me, therefore, that lead casing offers more advantages and less objection than any other form of protection to insulation as yet open to our use.

The third part of the question—viz., the mechanical protection of the casing, and hence the conductor—is not so difficult a matter. If an iron casing is used, little or no protection is needed. The pipe is strong enough in itself to withstand any ordinary abuse. If lead is used, however, it should be kept from contact with sharp stones, bits of glass, or metal, and have something about it to warn the ditch-digger before he strikes it with a pick. An ordinary square wooden box is oftentimes sufficient. If it does rot away it leaves a bed of soft mould. The box may be made of white oak, well creosoted, in which case it will last until the next generation finds something better. If the underground conductor is to come into practical

* Paper read before the Electric Light Convention at Pittsburgh.

every day use it must be so constructed that it may be tapped at any point as readily and with as much certainty as a water main is now tapped. How many miles of lead water pipes are now buried in our streets? They are not protected by boxes or conduits of any kind, yet it is comparatively rare that we hear of their failure. If such pipes filled with water can be laid in the earth without protection, why cannot a lead pipe filled solid full with copper and insulation be buried with even more success? Good workmen can certainly be found who can cut a conductor, splice in a branch and solder it, replace the insulation, and finally wipe a joint on the lead casing with as much ease and certainty as a plumber can make a joint in a lead water pipe and have it stand 100 pounds pressure.

In a general system of distribution there are two classes of conductors, one which we may call through mains or feeders and another service mains. A number of through mains may be bunched together in a cable under one casing, where they run in the same direction for a considerable distance. These may be drawn into conduits, as they are not to be used between the main distributing points. Service mains must, however, be so constructed that they may be tapped at any point, and that very readily. Large sums of money have been spent in New York and elsewhere on conduits for electric conductors. Are conduits necessary or desirable in electric lighting? Service wires are of no use whatever if placed within them, unless manholes are provided at every 100 feet. Though mains are certainly well protected when drawn into conduits, but at a great expense, no engineer would, I think, at this day, risk putting a conductor in any conduit which he would not be willing to trust under water or laid directly in the earth. Why not take one half of the money which these conduits cost and use it in buying thicker lead casing and bury the conductor in the ground or in a common wooden box?

The underground conductor of the future, I believe, will be formed with a core of copper cable, thoroughly insulated by any of the standard and well tried compounds, protected by a close fitting lead casing, thick enough to resist mechanical injury, and buried in the earth in such a manner that it may be tapped at any point. But where is the money coming from to pay for these conductors? Whenever electric light plants are installed in a thoroughly mechanical and substantial manner, with due regard to the most economical production of power, so that the electric light is perfectly reliable and obtains public confidence, then the money will be forthcoming.

When capital enough is invested in electric lighting to enable it to cope with the vast sums which have been accumulating these many years in the gas industry, then we shall see our dynamos driven by the waste heat and refuse products of the gas works, and our houses will be heated by gas and lighted by electricity.

ELEMENTS AND META-ELEMENTS.*

BY WILLIAM CROOKES, F.R.S.

Permit me, gentlemen, now to draw your attention for a short time to a subject which concerns the fundamental principles of chemistry, a subject which may lead us to admit the possible existence of bodies which, though neither compounds nor mixtures, are not elements in the strictest sense of the word—bodies which I venture to call "meta-elements." To explain my meaning it is necessary for me to revert to our conception of an element. What is the criterion of an element? Where are we to draw the line between distinct existence and identity? No one doubts that oxygen, sodium, chlorine, sulphur, are separate elements; and when we come to such groups as chlorine, bromine, iodine, &c., we still feel no doubt, although were degrees of "elementicity" admissible—and to that we may ultimately have to come—it might be allowed that chlorine approximates much more closely to bromine than to oxygen, sodium, or sulphur. Again, nickel and cobalt are near to each other, very near, though no one questions their claim to rank as distinct elements. Still I cannot help asking what would have been the prevalent opinion

among chemists had the respective solutions of these bodies and their compounds presented identical colours, instead of colours which, approximately speaking, are mutually complementary. Would their distinct nature have even now been recognised? When we pass further and come to the so-called rare earths the ground is less secure under our feet. Perhaps we may admit scandium, ytterbium, and others of the like sort to elemental rank; but what are we to say in the case of praseodymium and neodymium, between which there may be said to exist no well-marked chemical difference, their chief claim to separate individuality being slight differences in basicity and crystallising powers, though their physical distinctions as shown by spectrum observations are very strongly marked? Even here we may imagine the disposition of the majority of chemists would incline towards the side of leniency, so that they would admit these two bodies within the charmed circle. Whether in so doing they would be able to appeal to any broad principle is an open question. If we admit these candidates, how in justice are we to exclude the series of elemental bodies or meta-elements made known to us by Kruss and Nilson? Here the spectral differences are well marked, while my own researches on didymium show also a slight difference in basicity between some at least of these doubtful bodies. In the same category must be included the numerous separate bodies into which it is probable that yttrium, cerium, samarium, and other "elements" commonly so-called have been and are being split up. Where, then, are we to draw the line? The different groupings shade off so imperceptibly the one into the other that it is impossible to erect a definite boundary between any two adjacent bodies and to say that the body on this side of the line is an element, while the one on the other side is non-elementary, or merely something which simulates or approximates to an element. Wherever an apparently reasonable line might be drawn it would no doubt be easy at once to assign most bodies to their proper side, as in all cases of classification the real difficulty comes in when the border-line is approached. Slight chemical differences of course are admitted, and, up to a certain point, so are well marked physical differences. What are we to say, however, when the only chemical difference is an almost imperceptible tendency for the one body of a couple, or of a group, to precipitate before the other? Again, there are cases where the chemical differences reach the vanishing point, although well marked physical differences still remain. Here we stumble on a new difficulty; in such obscurities, what is chemical and what is physical? Are we not entitled to call a slight tendency of a nascent amorphous precipitate to fall down in advance of another a "physical difference?" And may we not call coloured reactions, depending on the amount of some particular acid present, and varying according to the concentration of the solution and to the solvent employed "chemical differences?" I do not see how we can deny elementary character to a body which differs from another by well marked colour, or spectrum reactions, while we accord it to another body whose only claim is a very minute difference in basic powers. Having once opened the door wide enough to admit some spectrum differences, we have to inquire how minute a difference qualifies the candidate to a pass? I will give instances from my own experience of some of these doubtful candidates. 1. Two closely allied bodies differ slightly in basic powers, and more decidedly also in their spectrum reactions, are they distinct entities? Probably, yes. 2. Two bodies have no distinctive spectrum reaction, and differ in basicity so slightly that their separation has hitherto proved to be impossible, but they differ decidedly in the colour of their oxides. Are they different? I should in this case also say yes. 3. Two bodies obtained from different minerals have no recognisable chemical difference, but there is a strong line in the phosphorescent spectrum of one which is absent in the other. What are we to say in this case? 4. A earth separated with enormous difficulty from its associates has a certain very definite phosphorescent spectrum. The addition of another body greatly intensifies one or more of the lines of the spectrum of the earth so separated, while upon the other lines in the spectrum of the same earth has no action. Is the basis of this earth simple or

* Presidential Address to the Chemical Society.

pound? 5. An earth showing no difference on fractionation has a phosphorescent spectrum not materially modified by the admixture of another earth, but the residual glow of one part of the spectrum as seen in the phosphoroscope is suppressed, while that of the other is not affected. Are we not here also dealing with more than one sort of molecule? 6. Earths, apparently the same, from different minerals, behave alike chemically and spectroscopically, with the exception that a certain line in the spectrum of the one is a little brighter than the corresponding line in the spectrum of the other. Again, where are we to draw the line? If an immediate decision were required, and a poll of the chemists in this room demanded, we should probably find the dividing lines placed in all positions among these seven cases. But to have only one rank in the elementary hierarchy, to class these obscure and indefinite bodies in the same rank with silver and chlorine and oxygen and sulphur, is as manifest an absurdity as it would be to put a speck of meteoric dust upon a level with the planet Jupiter because both may be called distinct members of the solar system. Is there no way out of this perplexity? Must we either make the elementary examination so strict that only some 60 or 70 candidates can pass, or must we open the examination doors so wide that the number of admissions is limited only by the number of applicants? The real difficulty we encounter by unlimited multiplication of elements arises from the periodic theory. That theory has received such abundant verification that we cannot lightly accept any interpretation of phenomena which fails to be in accordance with it. But if we suppose the elements reinforced by a vast number of bodies slightly differing from each other in their properties, and forming, if I may use the expression, aggregations of nebulae where we formerly saw, or believed we saw, separate stars, the periodic arrangement can no longer be definitely grasped. No longer, that is, if we retain our usual conception of an element. Let us, then, modify this conception. For "element" read "elementary group"—such elementary groups taking the place of the old elements in the periodic scheme—and the difficulty falls away. In defining an element, let us take not an external boundary, but an internal type. Let us say, *e.g.*, the smallest ponderable quantity of yttrium is an assemblage of ultimate atoms almost infinitely more like each other than they are to the atoms of any other approximating element. It does not necessarily follow that the atoms shall all be absolutely alike among themselves. The atomic weight which we ascribe to yttrium, therefore, merely represents a mean value around which the actual weights of the individual atoms of the "element" range within certain limits. But if my conjecture is tenable, could we separate atom from atom, we should find them varying within narrow limits on each side of the mean. The very process of fractionation implies the existence of such differences in certain bodies. Until lately such bodies passed muster as elements. They had definite properties, chemical and physical, they had recognised atomic weights. If we take a pure dilute solution of such a body, yttrium for instance, and if we add to it an excess of strong ammonia, we obtain a precipitate which appears perfectly homogeneous. But if instead we add very dilute ammonia in quantity sufficient only to precipitate one-half of the base present, we obtain no immediate precipitate. If we stir up the whole thoroughly so as to insure a uniform mixture of the solution and the ammonia, and set the vessel aside for an hour, carefully excluding dust, we may still find the liquid clear and bright, without any vestige of turbidity. After three or four hours, however, an opalescence will declare itself, and the next morning a precipitate will have appeared. Now let us ask ourselves, What can be the meaning of this phenomenon? The quantity of precipitant added was insufficient to throw down more than half the yttria present, therefore, a process akin to selection has been going on for several hours. The precipitation has evidently not been effected at random, those molecules of the base being decomposed which happened to come in contact with a corresponding molecule of ammonia, for we have taken care that the liquids should be uniformly mixed, so that one molecule of the original salt would not be more exposed to decomposition than any other. If, further, we consider the time which elapses before the ap-

pearance of a precipitate, we cannot avoid coming to the conclusion that the action which has been going on for the first few hours is of a selective character. The problem is not why a precipitate is produced, but what determines or directs some atoms to fall down and others to remain in solution. Out of the multitude of atoms present, what power is it that directs each atom to choose the proper path? We may picture to ourselves some directive force passing the atoms one by one in review, selecting one for precipitation and another for solution till all have been adjusted. In order that such a selection can be effected there evidently must be some slight differences between which it is possible to select, and this difference almost certainly must be one of basidity, so slight as to be imperceptible by any test at present known, but susceptible of being nursed and encouraged to a point when the difference can be appreciated by ordinary tests. Let us follow our atoms through another stage of fractionation. The ammonia has divided them into two groups, one of which displays just the minutest possible suspicion of greater basidity than the other. Let us repeat the first experiment again with these two groups. Again, we obtain from each a precipitate and a solution, so that we have now two precipitates and two solutions. It is evident that whereas the precipitate from the original salt was slightly less basic than that which remained dissolved, the second precipitate from the first precipitate must have its basic character still further diminished, while at the same time the second solution from the first solution must contain selected atoms of a slightly higher degree of basidity. The least basic at one end and the most basic at the other end are thus two removes each from the original; and treating them in the same way for a third time, we obtain two groups of atoms which are three removes from the centre. (The intermediate groups need not be here discussed. By systematic mixings they can be made to contribute their quota to the end groups.) By repeating this operation, not once or twice, but many hundreds of times, those atoms having a tendency to come down first always going one way, and those having a tendency to remain dissolved always going the other way, we, so to speak, educate the atoms, adding to them no fresh properties, but drawing out and giving free scope to properties that already existed, but that were previously masked. A similar absence of absolute homogeneity may possibly yet be traced in many of the "elements" if once the right reagents are selected, and if laborious chemists are to be found willing to devote years to researches barren to outward seeming. That this deviation from absolute homogeneity should mark the constitution of these molecules or aggregations of matter which we designate elements will perhaps be clearer if we return in imagination to the earliest dawn of our material universe, and, face to face with the Great Secret, try to consider the processes of elemental evolution. Going back to the "fire-mist," the "Ur-Stoff" of the German philosophers, or the "protyle," as, after Roger Bacon, I have ventured to call it, we see an infinite number of infinitely small ultimate, or rather ultimatissimate particles gradually accreting out of "formless stuff" and moving with inconceivable velocity in all directions. We find those particles which approximately have the same rate and modes of movement beginning to heap themselves together by virtue of that ill-understood tendency through which like and like come together—that principle by virtue of which identical or approximately identical bodies are found collected in masses in the earth's crust instead of being uniformly distributed. One of the first results of this massing tendency is the formation of certain nodal points in space, between which occur approximately void intervals. How such nodes and spaces come to be formed, we shall better be able to understand by a very few simple illustrations, choosing in the first instance, instead of ultimate atoms, living men and women. If we take any very frequented street in London, say, Fleet-street, at a time when the animated current runs equally in two directions; and if our rate of walking is somewhat greater than the mean speed of the other foot-passengers, we shall observe that the throngs on the footways are not evenly distributed, but consist of knots or groups—we might almost say blocks—with comparatively open intervening spaces. The explanation of this unequal

agglomeration of individuals is simple. Some two or three persons, whose rate of working is slower than the average, somewhat retard the movements of other persons, whether travelling in the same or in the opposite direction. In this manner a slight temporary obstruction is created. The persons behind catch up the obstruction, and so increase it; while those in the front of the obstruction, hurrying on unhindered at their former rate, leave a comparatively free and open space until they, too, find themselves delayed further on by another little group of loiterers. The same process may be observed with vehicles in the carriage way of much frequented streets. Thus, we find that differences in rate of movement are sufficient to arrange a multitude of moving bodies into a series of knots and gaps. In a crowded thoroughfare like Fleet-street, with two opposing human currents, much regularity in the sequence of these knots and voids is not to be expected; but if the observer happens to be walking with a crowd whose constituents are travelling in the same direction, the regularity becomes more apparent, and if, as is sometimes the case, a little rhythm is infused into the step by an accompaniment of music, the knots and gaps become so orderly that the distance between one block and another, measured in yards, will be found not to differ very greatly from one end of the road to the other. If, instead of men and women, we experiment with little grains of substances of approximately equal size, but differing in specific gravity, and, mixing them in a horizontal tube with water, we set them in movement by rhythmical agitation, similar phenomena will occur, and the heavy and light powders will sort themselves in a very regular manner. Descending to a lower degree of minuteness, we all know what occurs when an induction current is passed through a rarefied gas. Here the particles, being exempt from free will or caprice, implicitly obey the law I have attempted to illustrate, and out of infinite disorder, under the influence of the electric rhythm, sort themselves into beautiful forms of stratifications. Let us now return to our ultimate atoms, where the case, though much more complicated, is of the same character. We will suppose certain points in space where the first step in differentiation has been achieved. The ultimate particles have commenced to vibrate in their newborn energy in all directions, and with velocities ranging from zero to infinity. The law which we have traced from animated beings and coarse powders, down to the molecules of a rarefied gas, still holds good at this transcendental stage of matter, and the imagination can picture knots and voids gradually forming there as well as in Fleet-street. The slower particles will obstruct the quicker, the more rapid will rush up to the laggards in front, and we shall soon have groups forming in different parts of space. The constituents of each group whose rate of vibration is not in accord with the mean rate of the bulk of the components of that group will work to the outside and be thrown off to find other groups with which they are more in harmony. In time, therefore, a condition of stability is established between the various groups, and we may call these the molecules of our present system of elementary bodies. With regard to the place where atoms come into existence, it seems to me almost certain that if their existence has had a beginning, it has begun at the very edge of the protyle, or the confines of the universe, and that their subsequent migrations have always been inwards. In dynamical language every new position into which an atom can glide must be from a position of higher to a position of lower potential. If the atom has had a beginning is must therefore have been where the potential is highest—i.e., on the confines of the universe; and if it comes to an end, it must be where the potential is lowest, i.e., in the centre of overgrown stars; so that the extinction of the central part of a star when it becomes overgrown is that which puts a limit to the size a star can attain by attracting to itself surrounding matter. This assigning of the places where chemical atoms have their origin and where they meet with extinction seems the only—or almost the only—conclusion we can yet with confidence advance. From the above illustrations it will be seen that the constituent atoms of these molecules originally may not have been gifted with exactly the same speed or amplitude of vibration. In the

molecule of a certain group let the form of energy which has for a factor what we call atomic weight be represented by the figure 35.5; it follows from the foregoing exposition—which I have endeavoured to make clear—that while the great bulk of its component atoms have this atomic weight, a small percentage may vary from this figure to the extent of a decimal place, while a few others may stray as much as a whole number or two on one side or the other of the mean. The ultimate atoms whose rates are not exactly 35.5, but a little higher or lower than 35.5, will congregate around the 35.5 nucleus, forming a group whose average value will be 35.5. In like manner similar groups will be formed having the average rates of 80 and 127, while intermediate spaces will be cleared, the ultimate atoms which occupied these lone spaces being attracted to the chlorine, bromine, and iodine groupings. These groupings represent what at present we call elements, but which I conjecture may possibly consist each of an element and of a certain number of meta-elements, or each may be formed of a whole group of meta-elements, none of which greatly preponderate over the remainder. On the threshold we encounter an objection very clearly stated by Clerk Maxwell in his "Theory of Heat" (1871). "I do not think," says this eminent physicist, "that the perfect identity which we observe between different portions of the same kind of matter can be explained on the statistical principle of the stability of the averages of large numbers of quantities, each of which may differ from the mean, for if of the molecules of some substance, such as hydrogen, some were of slightly greater mass than others, we have the means of producing a separation between molecules of different masses, and in this way we should be able to produce two kinds of hydrogen, one of which would be somewhat denser than the other. As this cannot be done, we must admit that the quality which we assert to exist between the molecules of hydrogen applies to each individual molecule, and not merely to the average of groups of millions of molecules. The molecules of the same substance are all exactly alike, but different from those of other substances. There is not a regular gradation in the mass of molecules from that of hydrogen, which is the least of those known to us, to that of bismuth; but they all fall into a limited number of classes or species, the individuals of each species being exactly similar to each other, and no intermediate links are found to connect one species with another by a uniform gradation. In the case of molecules, however, each individual is permanent; there is no generation or destruction, and no variation, or rather no difference, between the individuals of each species. Our molecules are unalterable by any of the processes which go on in the present state of things, and every individual of each species is of exactly the same magnitude, as though they had all been cast in the same mould like bullets, and not merely selected and grouped according to their size like small shot." I think it evident that the statements here quoted, some of which involve no small amount of assumption, no longer accord with facts, for we actually do find variations between the properties of certain molecules which heretofore had been pronounced identical with each other. Take the case of yttrium. It had its definite atomic weight, it behaved in every respect as a simple body, an element, to which we might indeed add, but from which we could not take away. Yet this yttrium, this supposed homogeneous whole, on being submitted to a certain method of fractionation is resolved into portions not absolutely identical among themselves, and exhibiting a gradation of properties. Or take the case of didymium. Here was a body betraying all the recognised characters of an element. It had been separated with much difficulty from other bodies which approximated closely to it in their properties, and during this crucial process it had undergone very severe treatment and very close scrutiny. In short, until lately we might have said of it just what Clerk Maxwell says of hydrogen, that the quality which we assert to exist between the molecules of didymium applies to each individual molecule, and not merely to the average of groups of millions of molecules. But then came another chemist, who, treating this assumed homogeneous body by a peculiar process of fractionation, resolved it into the two bodies praseodymium and neodymium, between which certain distinctions are per-

ceptible. Further, we even now have no certainty that neodymium and praseodymium are simple bodies. On the contrary, they likewise exhibit symptoms of splitting up. Now, if one supposed element on proper treatment is thus found to comprise dissimilar molecules, we are surely warranted in asking whether similar results might not be obtained in other elements, perhaps in all elements, if treated in the right way. We may even ask where the process of sorting-out is to stop—a process which of course presupposes variations between the individual molecules of each species. And in these successive separations we naturally find bodies approaching more and more closely to each other. Dr. Auer von Welsbach, the discoverer of neodymium and praseodymium, remarks that these bodies “approximate more closely to each other than any two supposed simple bodies yet known.” Thus we approach nearer and nearer either to a regular gradation in the molecules or to the recognition of those intermediate links, which I have named “meta-elements” or elementoids. A suggestion here occurs that it may be to the presence of these meta-elements that so many of the chemical elements, while approaching closely in their atomic weights the values required by Prout’s law, deviate from it by a small but measurable amount. We can scarcely regard their approximation as purely accidental. We now come to the last objection pertinently put forth by Clerk-Maxwell to the hypothesis that the elements are not absolutely homogeneous. He writes:—“It is difficult to conceive of selection and elimination of intermediate varieties, for where can these eliminated molecules have gone to if, as we have reason to believe, the hydrogen, &c., of the fixed stars is composed of molecules identical in all respects with our own?” In the first place, we may call in question this absolute molecular identity, since we have hitherto had no means for coming to a conclusion save the means furnished by the spectroscope, while it is admitted that for accurately comparing and discriminating the spectra of two bodies they should be examined under identical states of temperature, pressure, and all other physical conditions. We have certainly seen, in the spectrum of the sun, rays which we have not been able to identify. We have supposed the cosmic cycle re-entering in successive periods, during a fall of temperature, the same region—say, for instance, where chlorine, bromine, or iodine have been formed. If most of the atoms present approximate more or less closely to 35.5, 80, or 127 the atomic weights of these three bodies they will be in consequence easily disposed of. But there may be besides a few intermediate atoms having, say, atomic weights of between 36 and 79 and between 81 and 126. These atoms will be attracted to the masses on one side or the other of the cyclical track. We can even imagine sparse atoms scattered so far from the centre line of track as to be midway between chlorine or bromine or between bromine and iodine; these wanderers likewise will be slowly picked up, and will gravitate to chlorine, bromine, or iodine; and, being thus accounted for, none need be eliminated. It is not impossible, moreover, that the elementary atoms themselves are not the same now as when first generated. For if an atom has commenced its existence at a certain epoch, and may go through such vicissitudes that it will cease to exist, it seems at least probable that it may undergo inward change. These vicissitudes probably directly affect only the primary motions which constitute the existence of the atom, but they indirectly, and only in a slight degree, affect those secondary motions which produce all the effects we can observe—chemical effects, heat effects, electrical, and so on. Thus, while the life of an atom may be waning away under the various experiences to which it is subjected, it may, and probably does, appear to us the same as at first. But perhaps not quite, so that atoms originally alike, taken from different minerals collected at widely separated stations on the earth, may have had sufficiently different past histories to have come to be markedly different in regard to the primary motions which elude our observation, and through the very slight influence which changes in the primary motions have on the secondary motions, may be just perceptibly different under our experiments. From this point of view a rare element, like a rare plant or animal, is one which has failed to develop in harmony with its surround-

ings. This view lends itself very naturally to the facts we encounter in our fractionation experiments. Where all the ultimate atoms have precisely identical rates of vibration any fractionation is impossible. Where such rates are not identical the process proves successful, and all the more easily the wider the differences among the vibration-rates of the ultimate atoms. The bodies thus split off necessarily very closely approximate to each other, and the further we push our fractionations the less marked are the differences. But as we review the series of elements arranged on the curve I adopted from Prof. Emerson Reynolds to illustrate my address on the “Genesis of the Elements,” delivered before the chemical section of the British Association (Birmingham meeting), we cannot fail to be struck by a consideration which at first sight appears absolutely fatal to the notion of the production of the elements from a series of “knots,” as just described. If the element which we call aluminium has been formed from ultimate atoms having rates of vibration of the rate 27, or a little more or less so as to give a mean of 27, and if the atoms between aluminium and the next element in the series have in this manner been sorted out to the one hand or the other, leaving a void between, we should expect that their properties would not differ very widely from each other, or at least that they would present considerable analogies. Now, to a certain extent this is actually the case. Upon aluminium follows silicon. We may, perhaps, conceive these two elements as springing from the differentiation of a nearly homogeneous swarm of ultimate atoms. But if we pursue the curve onwards what elements follow? Phosphorus, sulphur, and chlorine—bodies heterologous with each other, and heterologous with silicon. We can scarcely imagine original atoms, so to speak, in doubt which of two aggregations they should join, the one being silicon and the other phosphorous. Nor can we conceive of anything being split off from sulphur which should make even the slightest approximation to chlorine. It appears to me, however, that these difficulties are more apparent than real. In the Birmingham address already referred to I asked my audience to picture the action of two forces on the original protyle—one being time, accompanied by a lowering of temperature; the other, swinging to and fro like a mighty pendulum, having periodic cycles of ebb and swell, rest and activity, being intimately connected with the imponderable matter, essence or source of energy we call electricity. Now, a simile like this effects its object if it fixes in the mind the particular fact it is intended to emphasize, but it must not be expected necessarily to run parallel with all the facts. Besides the lowering of temperature with the periodic ebb and flow of electricity, positive or negative, requisite to confer on the newly born elements their particular atomicity, it is evident that a third factor must be taken into account. Nature does not act on a flat plane; she demands space for her cosmogenic operations, and if we introduce space as the third factor all appears clear. Instead of a pendulum, which, though to a certain extent a good illustration, is impossible as a fact, let us seek some more satisfactory way of representing what I conceive may have taken place. Let us suppose the zigzag diagram not drawn upon a plane, but projected in space of three dimensions. What figure can we best select to meet all the conditions involved? Many of the facts can be well explained by supposing the projection in space of Prof. Emerson Reynolds’ zigzag curve to be a spiral. This figure is, however, inadmissible, inasmuch as the curve has to pass through a point neutral as to electricity and chemical energy twice in each cycle. We must therefore adopt some other figure. A figure of eight or lemniscate will foreshorten into a zigzag just as well as a spiral, and it fulfils every condition of the problem. Such a figure will result from three very simple simultaneous motions. First, a simple oscillation backwards and forwards (suppose east and west); secondly, a simple oscillation at right angles to the former (suppose north and south) of half the periodic time, i.e., twice as fast; and thirdly, a motion at right angles to these two (suppose downwards), which, in its simplest form, would be with unvarying velocity. If we project this figure in space we find on examination that the points of the curves where chlorine, bromine, and iodine are formed come close under each other; so also will sulphur, selenium, and tel-

rium; again, phosphorus, arsenic, and antimony; and in like manner other series of analogous bodies. It may be asked whether this scheme explains how and why the elements appear in this order? Let us imagine a cyclical translation in space, each revolution witnessing the genesis of the group of elements which I previously represented as produced during one complete vibration of the pendulum. Let us suppose that one cycle has thus been completed, the centre of the unknown creative force in its mighty journey through space having scattered along its track the primitive atoms—the seeds, if I may use the expression—which presently are to coalesce and develop into the groupings now known as lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, and chlorine. What is most probably the form of track now pursued? Were it strictly confined to the same plane of temperature and time, the next elementary groupings to appear would again have been those of lithium, and the original cycle would have been eternally repeated, producing again and again the same 14 elements. The conditions, however, are not quite the same. Space and electricity are as at first, but temperature has altered, and thus, instead of the atoms of lithium being supplemented with atoms in all respects analogous with themselves, the atomic groupings, which come into being when the second cycle commences, form, not lithium, but its lineal descendant, potassium. Suppose, therefore, the *vis generalis* travelling to and fro in cycles along a lemniscate path as above suggested, while, simultaneously, temperature is declining and time is flowing on—variations which I have endeavoured to represent by the downward sink—each coil of the lemniscate track crosses the same vertical line at lower and lower points. Projected in space, the curve shows a central line neutral as far as electricity is concerned and neutral in chemical properties—positive electricity on the north, negative on the south. Dominant atomicities are governed by the distance east and west from the neutral centre line, monatomic elements being one remove from it, diatomic two removes, and so on. In every successive coil the same law holds good. As the mighty focus of creative energy goes round we see it in successive cycles sowing in one tract of space seeds of lithium, potassium, rubidium, and cesium; in another tract, chlorine, bromine, and iodine; in a third, sodium, copper, silver, and gold; in a fourth, sulphur, selenium, and tellurium; in a fifth, beryllium, calcium, strontium, and barium; in a sixth, magnesium, zinc, cadmium, and mercury; in a seventh, phosphorus, arsenic, antimony, and bismuth; in other tracts, aluminium, gallium, indium, and thallium; silicon, germanium, and tin; carbon, titanium, and zirconium; while a natural position, near the neutral axis, is found for the three groups of elements relegated by Prof. Mendeleeff to a sort of hospital for incurables—his eighth family. We have now traced the formation of the chemical elements from knots and voids in a primitive, formless fluid. We have shown the possibility, nay, the probability, that the atoms are not eternal in existence, but share, with all other created beings, the attributes of decay and death. We have shown, from arguments drawn from the chemical laboratory, that in matter which has responded to every test of an element, there are minute shades of difference which may admit of selection. We have seen that the time-honoured distinction between elements and compounds no longer keeps pace with the developments of chemical science, but must be modified to include a vast array of intermediate bodies “meta-elements.” We have shown how the objections of Clerk-Maxwell, weighty as they are, may be met; and, finally, we have adduced reasons for believing that primitive matter was formed by the act of a generative force, throwing off at intervals of time atoms endowed with varying quantities of primitive forms of energy. If we may hazard any conjectures as to the source of energy embodied in a chemical atom, we may, I think, premise that the heat radiations propagated outwards through the ether from the ponderable matter of the universe, by some process of nature not yet known to us, are transformed at the confines of the universe into the primary—the essential—motions of chemical atoms, which, the instant they are formed, gravitate inwards, and thus restore to the universe

the energy which otherwise would be lost to it through radiant heat. If this conjecture be well founded, Sir William Thomson's startling prediction of the final decrepitude of the universe through the dissipation of its energy falls to the ground. In this fashion, gentlemen, it seems to me that the great question of the elements may be provisionally treated. Our slender knowledge of these first mysteries is extending steadily, surely, though slowly. While certain ardent chemists are testing the commonly received view of the homogeneity of the elements by methods of fractionation, others, by means of the spectro-scope, are carrying on another form of assault; each worker bent on the one idea of undermining the secret. I earnestly recommend such researches. However successfully pursued, they cannot, I know, lead directly to any results capable of being turned to industrial account. If, however, we consider the small but firm foothold we have gained in pursuit of this line of investigation, I venture to think there is reasonable ground to hope that these researches may tend to place chemistry upon a new foundation, by penetrating down through loose, superficial matter to the solid rock. The application of the luminous principle of evolution has remodelled and vivified many branches of biology, and philosophers are eagerly invoking its aid in other departments of science. I would fain hope that I may not be deemed unduly sanguine in believing that the application of this regenerating principle to chemistry will produce far-reaching effects on its harmonious and progressive development.

THE UNDERGROUNDING OF ELECTRIC ARC WIRES.*

BY W. W. LUGGETT.

(Concluded from page 305.)

The question is frequently asked, If telephone and telegraph wires can be undergrounded, why cannot arc wires? The reason is plain, leakage or escape can be supplied in the former by additional battery power, but an arc-light generator is a queer specimen of mechanics. It starts a mild current, and this passing back around its field magnets builds them up; the increased magnetism induces greater impulses in the bobbins of the armature the current thus increased continues to pass through the line and back around the field magnets until the current has reached its maximum. It is therefore apparent that anything which keeps the current from the line, not only steals the quantity which has escaped, but prevents just so much current from passing back around the field magnets, and to that extent robs the machine of its capacity to generate a current. These machines are capable of taking care of the small amount of loss at the insulators in the pole and line system, but when this is multiplied many times, as in an underground conduit, it is so robbed of its power to recuperate that the resulting lights are necessarily reduced in number, and are weak and sickly. Operations looking to the undergrounding of arc light wires have been prosecuted on a large scale at New York, Brooklyn, Chicago, Philadelphia, and Washington. Notwithstanding all reports to the contrary, I find that at New York, although the Subway Commission has expended vast sums of money, and has succeeded in burying certain telephone and telegraph wires, no arc light line has up to this time been buried in New York city, and this is fully corroborated by the report of the Board of Electrical Control of January 6, 1888.

At Brooklyn, N.Y., the Board of Commissioners of Electrical Surveys instituted thorough investigation of this subject in 1886, and in its report of December 30, 1886, says: “With regard to electric light conductors this board has found no device which would with certainty, in its opinion, enable the wires carrying arc light currents to be safely and successfully operated in the same conduit with telephone and telegraph conductors without disturbance or injury to the latter. But the board desires to say, emphatically, that those fluent critics who talk of putting electric light conductors

* Paper read before the National Electric Light Convention at Pittsburgh.

underground, making no distinction between arc lights and incandescent lights, or between the arc lights of different systems, are ignorant of the alphabet of the subject." The president of the board visited all the principal cities in Great Britain and Europe. He found no arc light wires underground, and although a few years since such wires were trained in the Paris sewers, they have been removed, and no arc light wires are now allowed therein.

The Brooklyn Commission made another report, December 15, 1887, and on this topic says: "As was fully explained in the last report, the subject of underground conduits for arc currents is the one which presents the most numerous and novel difficulties. Since it has been impossible for Brooklyn to take the lead in the experimental solution of these, the only remaining course was to watch carefully the progress of experiments in other cities. This has been done both by correspondence and by personal visits of members of the board. The principal cities in which experiments of this kind have been in progress are New York, Chicago, Philadelphia, Baltimore, and Washington. In one or another of these several systems which were regarded with favour a year ago have since developed defects or even come to entire failure. It cannot be said that any system has yet been completely proved to be permanently satisfactory. There are one or two, however, which promise well, and this board awaits with attentive interest their further trial, regretting only its inability, through the cause already specified, to co-operate in the experimental investigation of the different and delicate questions involved. There are no arc light wires underground up to this time in Brooklyn.

At Washington in 1884 cables were laid in F street from 9th to 15th. In a few months it was necessary to dig up the same. Later, there was much more trouble, and it was all taken up and relaid. About one year after the first laying it was wholly abandoned because they could not make it work. In 1885 they laid cables on Pennsylvania-avenue, from 9th to 1st streets, and imported an expert from Antwerp to lay them. Twelve cables were laid in solid cement, and no expense spared to insure success. They proved an utter failure. The avenue was dug up many times. The wires were in September, 1887, mostly out of service, and the remainder were in such bad shape that they would require constant repairing or have to be abandoned. An officer of the Washington company writes me under date of September 12, 1887:—"We have many committees coming here to see what we have accomplished, as they have heard that we have met with great success and so forth. We will say to you, that our experience, after the outlay of many thousand dollars, is this: have nothing to do with underground cables for arc lighting if you can possibly avoid it. Many will tell you that it is perfectly practicable. Look out for such parties. They are probably interested directly or indirectly in cables. There is a big hobby in that branch of business. There is no city or town in the world where a cable has been made to work two years that has been subjected to 2,000 volts of pressure." This Washington company is using lead-covered cables with success for incandescent work; but as to the undergrounding of arc light wires, confirmed as late as Feb. 7, 1888, they report that out of 14 miles of arc light cable in 14 different circuits all have proved total failures, and have been abandoned except a very small amount.

At Philadelphia elaborate experiments have been prosecuted. All kinds of cables have been employed, and a great variety of conduits—great trouble has been experienced. The systems largely employed were such having ducts through which the cables were drawn—in most cases the insulating compound rapidly deteriorated, and became useless; in others it would be rotted, and become water soaked. Where lead covered cables were used in conduits where creosote was employed, the effect was to rapidly oxidise the lead covering, and disintegrate the same. It was found that gas could not be kept from the ducts, although apparently gas tight, many explosions followed. Recourse was then had to ventilation by lamp posts, but the trouble was not corrected. After several explosions in one system, in which persons and property were injured, a power fan was adjusted to force air through the conduit, deeming it better to do so, than

to draw the air through, which might simultaneously draw in gas. When, shortly afterwards, the lighting company was congratulating itself that it had overcome the difficulty, a tremendous explosion ensued, extending for a long distance, ripped up the street, and broke a large plate glass window. That entire system of lights had to be abandoned. It was some six months ago determined by the manager that as a result of experience no conduit would suffice for arc light wires in which there were open ducts, and that success lay in the employment of lead covered cables buried solid. This plan suggested by the city electricians was tried and success seemed assured, but they now report the experiment unsuccessful. The section covered is not great, but three bad grounds recently developed; two were repaired, but the third necessitated the temporary cutting out of a part of the line and the training of wires on poles until the earth may thaw and enable access to be had to the wires. The various companies of Philadelphia are at a loss what to try next. At this point I would note that these demands for a system for arc light wires have greatly stimulated inventive ingenuity, but as yet without success. Out of the 72 patents that have been issued in this line, 53 of them have emanated from Philadelphia, New York, Boston, Brooklyn, Wilmington, Camden and Washington, all being in the immediate vicinity of the places where the operations were being conducted. The others were mostly from the general vicinity of Chicago.

Now as to Chicago, much has been said of its system. A visit to Chicago satisfied me that its electric arc light industry was being strangled. A few blocks in the immediate heart of the city were using electric light very lavishly, but the area lighted is scarcely a half mile square. This small area is served from no less than nine separate plants, formerly belonging to as many companies, but now consolidated into one. A letter under date of September 20, from an officer of the Consolidated Company, explains the situation there. He says: "We have had an enormous amount of trouble with our underground arc light circuits, averaging, I would say, for the last three months, one burn out every day. The expense of reconstruction and the losses in rebates have been enormous, and the annoyance to our customers more damaging still. Commencing in April last we bought out some nine arc light plants in Chicago, and have proceeded to concentrate them into four main stations burning about 1,100 lights; their owners had all been using underground conductors composed for the most part of okonite, kerite, callender, and underwriter's wires. Every one of these insulators has failed constantly. The only thing that has held up at all is lead covered cable, and we have been driven to the great expense of taking out every foot of the old constructions and substituting new lead covered cables throughout. This work is not yet done. Our people are confident that a large business awaits us here; but its development will depend entirely upon service. These lead circuits may fail much sooner than is anticipated, and it is almost certain that we shall be compelled to reduce the number of lights upon a circuit—a very difficult matter in a city like Chicago. Our conduit space is already filled along the main routes, and additional conduits will be necessary. The constant tearing up of the pavements for all kinds of purposes makes our street departments very unwilling to grant permits for laying additional conduits, and several times they have been refused altogether. I would say here that arc light business in Chicago has developed entirely since the passage of the underground ordinance of 1881. The result has been the multiplication of small isolated plants and the formation of the nine small central station plants bought out by this company. None of these plants made any money. It was impossible for them to do so, operating underground and upon so small a scale. No streets have ever been lighted by electricity here, in fact the whole industry is in a very backward condition, and is likely to remain so, except in the most densely crowded portion of the city, unless some arrangement can be made with the city authorities for overhead wires. The city is trying an experiment of its own, in lighting Chicago River, which will, I am confident, demonstrate the truth of the foregoing statement; and in the course of a year I hope that our city fathers will permit overhead lines in many

places where public convenience demands electric lights, while underground construction would forbid it."

At Milwaukee, Wis., three systems have been tried and abandoned, i.e., a wooden trough, plain and tarred iron pipe, and grooved wood. A fourth, consisting of tile conduits, with a heavily insulated, but not lead covered, cable has recently been introduced, and is now being tested. The company doubts whether it will stand the trying spring season. At Detroit, the Thomson-Houston Company employed a cable of the most expensive and approved character in the Dorsett conduit, and the mechanical work was of the best quality. While the cable was new the results were fair, though loss by seepage rendered it impossible to produce normal lights. It was found impossible to operate telephone wires in the same or adjacent pipes. The company soon abandoned the system, and when its cable was removed it was found the insulation had so rotted or softened that considerable lengths of the wire in many places were stripped bare.

With the alternating system some wires have been undergrounded in Springfield, Mass., and in Denver, Colorado, and a small amount in Pittsburgh, but the voltage is only half that of the arc light systems, and even with this low voltage the lead covered cables have not been in use long enough to determine the question of their success. The difficulty from explosions of gas has been met with many times at Chicago, New York, and elsewhere, as well as at Philadelphia, and seems insurmountable where gas is employed. At New York men have been suffocated in the main holes, and in the Western Union Building the escape of gas from their conduits has been almost unbearable. At Detroit an explosion took place in October last in the middle of the night, in a fire alarm conduit with closed manholes, and in which no wire had ever yet been placed. It doubtless occurred through the admixture of illuminating gas and sewer gas, or other exhalations, in proportions, to explode spontaneously. The manhole cover was thrown high into the air, the street torn up, and the paving blocks scattered over a distance of eighty feet or more. The problem of undergrounding arc light wires is by no means solved, but appears to-day to be further than ever from solution, owing to the utter failure of systems which apparently had all the elements to insure success. In this emergency, municipal bodies must suit their action to the fact. To legislate arc light wires beneath the ground when no practical system is presented for accomplishing that end, is actually and literally to bury the system. When a city is so sanguine of the soundness of its judgment, the remedy would seem to be for the city to provide conduits and the necessary cables, guarantee their success, and then compel lighting companies to rent their lines at a proper figure, or failing so to do to quit the field. Summary action on any other basis is incompatible with that justice and equity which it is the inherent right of every person to demand and receive. Any other course is to discourage enterprise and to ruthlessly impair or destroy capital invested in good faith. The difficulty usually met with is a peculiar and unreasonable one. Municipal and legislative bodies view with suspicion the lighting companies, their officers, stockholders, and everybody connected with them. It seems to be assumed that because the companies make a certain showing of facts the facts must necessarily be exactly the contrary, and they legislate accordingly. Thus at Detroit, in opposition to letters produced by the lighting company, alleging repeated trials and failures at Washington, Philadelphia and Chicago, the then mayor, unquestionably in good faith, reported to the council as the result of his personal investigation upon the spot, that no electric light wires had ever been buried in the city of Washington, a most glaring error; yet this was followed by a report of the committee and unanimously adopted by the council, that underground systems of electric arc light wires were entirely practicable and were in successful use at Washington, New York, Philadelphia and elsewhere. At Cleveland recently the strongest argument in the underground struggle advanced by the city was that the wires of the Thomson-Houston Company, of Detroit, were operating underground in the Dorsett systems, whereas not a foot of arc light wire is undergrounded in Detroit. To combat this unreasonable and unreasoning prejudice, the question whether any system

yet discovered is practical and sufficient for the purpose should be thoroughly and exhaustively examined, an elaborate report made and published with full data, which the conclusions are reached. This should be by a board of competent and eminent men of national reputation entirely disconnected from the electrical business, such as could be gathered from the scientific chairs of the largest colleges and polytechnic institutes, and it would with the interested companies of this association to contribute from their own funds, or to influence the necessary contribution by the councils of their respective cities, to the necessary expenses of such an inquiry.

COMPANIES' MEETINGS.

THE MAXIM-WESTON ELECTRIC COMPANY.

A meeting of the shareholders of the Maxim-Weston Electric Company, Limited took place on Wednesday the 28th ult., at the City Terminus Hotel, Mr. Hugh Watt, M.P., in the chair.

The notice calling the meeting was read by the Secretary John Wright, and the report of the directors was taken as read.

The Chairman, in the course of a long address, said: "The holders form now an almost wholly new body from that which when we took office. The new board undertook to reconstruct the Company and to place it on a proper financial basis, but with a conception of the difficulties that were before them, or a little aid they would receive from the shareholders. When the directors took office, the fact was disclosed that the Company was virtually insolvent, with no profitable contracts in hand but with unprofitable ones, to fulfil which would entail a loss of over £10,000 per annum. Hence there appeared before it a near prospect of liquidation. The list of shareholders at the time consisted of less than 1,000, and so little faith had those gentlemen in the future of electric lighting, the feverish period of electricity had passed away, that to prevent the Company from going into liquidation only £550 was subscribed. It was therefore, very far for the directors to put their hands in their pockets, and the assistance of their friends, to find capital to carry on the Company. I do not want to say where the money came from or who found it, because that would involve a personal reflection, but sufficient was forthcoming to wipe off the debts, to pay off useless warehouses and unprofitable City contracts, and place the Company upon a sound financial basis. That was about a year ago, and during that period the original shareholders, those who have since come in, have subscribed a certain amount of capital; but the bulk of that which has enabled us to take new, to lay down adequate plant, and to carry on the business, has been found by the board, with the exception of some £4,000 or £5,000 subscribed by the shareholders to date. The dividends paid by the present board have been twice that amount, so that I think that at all events is pretty square as far as the existing shareholders are concerned. You may say that has reference to the end of 1886, and is true. With regard to 1887, you probably expected a dividend. I also expected one, and up to November had reason to expect one. At that date we had entered into provisional contracts entitling me to assume that after payment of a dividend of 5 per cent. there would be a considerable balance remaining, but three large contracts fell off which left us with a deficiency of about £3,000 of profits. No occasion to mourn that more than I have, because it means a loss upon my large holding. At the same time during the past year we have carried out an amount of business greatly in excess of years, but we have met with opposition we could not foresee—loss from persons who had sold £1 worth of goods for less than £1, have given a vast amount of attention to the Company in my position as chairman, but that position I am ready to resign into your hands should you wish me to do so. With regard to the accounts Mr. Wright will read you the report of the auditors."

The report was then read.

The Chairman (continuing): "The view of the auditors is in and calculated to place impartial data before the shareholders, regard to no provision being made for bad and doubtful debts—the receipt of the auditors letter the directors decided to transfer the entire balance of profit to a reserve fund. To the reserve account is a sum placed against bad and doubtful debts from the Lighting Power and Generator Company, which sum was added to the period ending 1885. Last year we passed no sum to the reserve account, because we did not think there was any profit any such sum requiring to be so passed. The shareholders were for a dividend, and had we passed a sum to that account at the end of 1886 we should not be able to pay that dividend. The holders got the advantage, but this year, looking at the case, the directors decided upon passing the amount of the credit of this reserve account, which was absorbed in it to and including 1885. We found that the manufacture of the dynamo, sufficient to run 500 lights, would necessitate putting other machinery. Since 1883 the accounts have been prepared looked after by Mr. Alabaster, late of the firm of Messrs. Waterhouse, and Co., and I have had nothing to do with them. I told him that the item of £1,555 ought to be £650 more. Alabaster did not agree with me, and therefore the accounts printed as you see them. There is a slight discrepancy in the sheet, owing to the dividend last paid having absorbed £25 more."

we calculated. The additional plant put down at the factory enables us to manufacture Maxim-Weston and Watt dynamos. I agree with Mr. Dever that it is desirable to charge nothing more to patents; but an electric company is not like a butter business, where you sell your product and pocket your profit. Nor do I agree with a noble lord, the chairman of another company, in assuming that systems are now perfected. In my opinion, no system is perfected. We are proceeding on our own lines, and believe we are right. However desirable it may be not to add anything to patents account, as long as the present competition is going on, and also monthly improvements are being made, we cannot stand still. We must keep abreast with the times, and we must meet the formidable competition we experience on every hand. The expenditure has been entailed entirely upon Maxim-Weston patents. We were very much inconvenienced by the fire in New York, which deprived us of incandescent lamps, for the supply of which the Company was originally formed. We have been compelled to tender for Swan lamps. We are very much indebted to our manager for his great services, and also to our secretary (Mr. Wright) for his indefatigable exertions. Our manager is a competent electrician; he experiments continually, and has done for us service worth five times his salary. I found on close examination that our incandescent lamps cost us 7s. 6d. each, and we made experiments which reduced the cost to something like 3s. 9d. That led to the dismissal of a large number of supernumeraries; but we could not get over the difficulty of durability. I thought the best way was to cease to manufacture ourselves and to rely upon the American company. In the United States £30,000,000 or £40,000,000 sterling is invested in electric lighting. We now know the new lamps are good, and compare favourably with anything that can be produced in America. We have had no litigation with the Edison-Swan Company, and we do not expect any because we have a perfectly sound patent that we can sustain. We have not succeeded in obtaining as many orders simply for the reason I mentioned in regard to our competitors, and in many cases to a loss of contracts. It is useless attempting to carry on an electric lighting company unless you go on making improvements. If you decide to stop improvements I resign my seat, because I despair of such a company, and know that it will soon be out of the running. We are in a better position than the American company, as we can turn out plant equivalent in candle-power to the American plant at less cost. One cause of that is the protective system in America, which places them at a disadvantage of nearly 30 per cent. The asset of the Sun Company—the shares of which we got for nothing—I am told is worth \$2,000, and not the small amount set down in the balance-sheet. The sundry debtors includes an amount largely owing by the Chancellor of the Exchequer, who is very loth to part with money. It is a matter of regret to the directors that the shareholders have not applied, but to a trifling amount, for the last issue of shares. The money would have been of great service to the Company. I took my full proportion, and from time to time the directors have done their duty in relation to the Company. The new Watt patents necessitated a good deal of outlay. They were called so out of courtesy to me; but others were associated with me in them, some of whom I had to buy out. I have expended last year from £2,000 to £3,000. These patents do not belong to this Company. It was thought to buy them, but the directors resolved to leave it an open question; but I have secured the manufacturing patents to this Company on a royalty. If of no value, you pay nothing for them; if they are of value, a very large proportion of the profit comes to this Company. There has been no cost in the matter to the Company. I believe we will secure for these patents enormous sales, and at an early date. We shall be able to compete for Government business at an immense saving upon anything that has taken place previously. I think this Company is well in the van with regard to electric lighting. In conclusion, I have no hesitation in saying that the position of this Company to-day is better than ever it was. The chairman concluded by moving the adoption of the report.

Mr. George Howell, M.P., seconded the motion.

Mr. Louis Swaby proposed as an amendment: "That the report and accounts should not be passed, but that a committee of enquiry should be appointed to investigate them." He denied that he had had anything to do with drawing up the report, although he was a director, and he contended that Mr. Howell had been improperly elected. He went on to read voluminous correspondence between himself and Mr. Watt, including a letter marked private, to which objection was taken.

A long discussion ensued and ultimately a committee was appointed to investigate the Company's affairs and reports to a general meeting, which was then and there fixed for April 25.

The Chairman quite approved of the committee, and he was prepared to fully meet every one of Mr. Swaby's statements.

A vote of thanks to the chairman closed the proceedings.

PROVISIONAL PATENTS, 1888.

MARCH 23.

- 4453. Improvements in railway signalling, which he names "Shakeshaft's automatic electric-railway signal." James Shakeshaft, Ashton, Tamecote, Northamptonshire.
- 4454. An improved method of administering galvanic currents for curative purposes. Augustus Collingridge, 97, Newgate-street, London, E.C.
- 4474. Improvements in structures for supporting electric and other conduits, and for facilitating access to buildings. Bernhard Dukes, 226, High Holborn, Middlesex. (Maurice J. Hart, United States.)
- 4489. An improvement in holders for electric glow lamps. Edward Frederick Hermann Heinrich Lauckert and Ernst Hermann Haasael, 28, Southampton-buildings, Chancery-lane.

MARCH 24.

- 4523. Telegraphic and telephonic apparatus, part being applicable to other electrical purposes. James Keiman, 14, Young Street Quay Street, Man. Lister.
- 4524. Improvements in portable galvanic batteries. William Joseph Starkey Barber Starkey, 70, Market Street, Manchester.
- 4559. Improvements in electric arc lamps. Frederic de Wolfers, 3, Deron Road, Herne Hill, London, S.E.
- 4561. An improved battery jar. Charles Alva Brown, Somerset Chambers, 151, Strand, London.

MARCH 26.

- 4568. Improvements in or relating to conductors for electrical and acoustic purposes. Samuel Williams, 8, Rutland-place, Newport, Monmouthshire.
- 4579. A new or improved electrical apparatus for combining an electrical alarm with the ordinary mechanical alarm. James Joseph Dillon, 10, Lemster-street, Dublin.
- 4593. Improvements in electrical batteries and methods of closing the same. Frederick Lawrence Rawson, 11, Queen Victoria Street, London, E.C., and William White, 40, Ranelagh Road, W. Rensden Junction.
- 4626. Improvements in the electrolytic production of metals. Carl Hoejmet, 28, Southampton-buildings, London, W.C.
- 4627. An improved method of using incandescent electric lights. Charles Wells and Frederick J. Goad, 22, Southampton-buildings, Chancery-lane, W.C.

MARCH 27.

- 4659. Improvements in apparatus for making and breaking electrical circuits in connection with call or alarm boxes and recording the same automatically on dials. Frederick Thomas Schmidt, Sunbridge Chambers, Bradford, Yorkshire.
- 4673. Improvements in and connected with apparatus for the generation and utilization of electric currents. Philip Middleton Justice, 55 and 56, Chancery-lane, Middlesex. (Charles Heiser, United States.) (Complete specification.)

MARCH 28.

- 18,036. A new or improved coin-operated induction cell. Wm. Riley Pope, 70, Market Street, Manchester. Received 28th March, 1888, antedated 31st August, A.D., 1887, under International Convention.
- 4769. Improvements in and relating to telephonic apparatus. Henry Harris Lake, 45, Southampton-buildings, London. (International Dudley Signal Co., United States.)
- 4764. Improvements in portable galvanic and electro-magnetic batteries for medical purposes. Arthur Lake Fry, 34, Southampton-buildings, London, W.C.

MARCH 29.

- 4804. A new switching arrangement for electric signalling, telephones, telegraphs, &c., by means of which any number of instruments may be worked on one single line, one with the other. Edward Jesse Piper, Tufton-place, Northiam, Sussex.
- 4819. Battery for general electro-medical use, or as electrical dumbbells, Indian clubs, and the like, for muscular exercise with electrical current of any desired strength during such exercise. William George Johnson, 58, New Bond-street, Middlesex.

COMPLETE SPECIFICATIONS ACCEPTED.

MARCH 21, 1887.

- 4220. Improvements in instruments for measuring electric currents. John William King, 13, St. John's square, London, E.C.

MARCH 25, 1887.

- 4447. A new or improved apparatus for measuring, indicating, and recording currents of electricity. Paul Bedford Elwell, 70, Market-street, Manchester.

MARCH 31, 1887.

- 4832. Improvements in the manufacture and construction of carbon "plates" or electrodes for use in primary batteries and for electro-metallurgical, electrolytical, and other electrical purposes. Henry Liepmann, of The Liepmann Carbon Co. (Limited), 77, Chancery-lane, Middlesex.

FEBRUARY 29, 1888.

- 3097. An improvement in holding the plates of secondary voltaic batteries. Bernard Mervyn Drake and John Marshall Graham, 28, Southampton-buildings, Chancery-lane, London, W.C.

SPECIFICATIONS PUBLISHED.

1887.

- 4225. Electricity meters. G. Hookham. 1s. 1d.
- 5562. Generating, &c., electricity. W. Maxwell. 6d.
- 5709. Dynamo-electric machines. A. I. Grover. 8d.
- 5867. Secondary batteries. W. Kingland. 8d.
- 6163. Telephones. H. F. Jackson. 8d.
- 6294. Electrolytic treatment of zinc, &c. A. Watt. 6d.
- 17,704. Telephones. A. C. Heats. 6d.

CITY NOTES.

West Coast of America Telegraph Company. The traffic receipts of the West Coast of America Telegraph Company for March were £4,175.

Brazilian Submarine Company. The traffic receipts of the Brazilian Submarine Telegraph Company (Limited), for the week ended March 30 amounted to £4,315.

Direct Spanish Telegraph Company.—The estimated traffic receipts of the Direct Spanish Telegraph Company for the month of March are £1,900, against £1,863 for the corresponding period of last year.

Dissolution of Partnership. Messrs. Heenan and Kroule, of Newton Heath, Ironworks, Newton Heath, Manchester, have dissolved partnership. The business will, however, be carried on by Mr. Richard H. Heenan.

Telephone Company of Austria. The directors of the Telephone Company of Austria have declared an interim dividend at the rate of 6 per cent. per annum on their preference shares for the six months ending 31st ult., payable, less income-tax, on and after April 9th.

Oriental Telephone Company.—The directors of the Oriental Telephone Company have decided to recommend a dividend for the year ending December 31 last of 2 1/2 per cent., free of income tax, on the paid-up capital of the Company other than the vendor's shares.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company for the week ended March 30, after deducting the "fifth" of the gross receipts pay-

able to the London Platino Brazilian Telegraph Company (Limited), were £3,491.

West Indian and Panama Telegraph Company.—The estimated traffic receipts of the West Indian and Panama Telegraph Company for the half month ended March 31, are £3,703 as compared with £3,430 in the corresponding period of 1887. The December receipts, estimated at £5,577, realised £5,612.

The Julien Electric Company Limited.—A new company is registered under this title. Capital, £1,000,000, in 10,000 shares of £10 each. The first subscribers are:

A. W. Ripping, 9, Woodville-road, Midway-road, N.
R. R. P. Brathwaite, 56, Osnaburgh-street, Regent's Park.
A. F. Stokes, 5, Birchm-lane, E.C.
T. B. Wear, 50, Devonshire-chambers, Bishopsgate-street, E.C.
A. Barton, 30, Malvern-road, Dabston.
R. Gordon, Acorn-grove, New Malden, Surrey.
A. G. Pavill, 2, Cavendish-terrace, Frant-road, Thornton Heath.

Companies of the Month.—The following Electrical Companies have been registered during the month of March:—

Charles L. Baker and Co. (£5 shares)	£25,000
Electrical Works Construction and Maintenance Co. (£1 shares)	2,000
St. James's and Pall Mall Electric Light (£5 and £1 shares)	100,000
Bournemouth Electric Light and Power Co. (£5 shares)	4,000
Gulcher New Electric Light and Power Co. (£1 shares)	70,000
Exeter Electric Light (£10 shares)	20,000
Julien Electric Co. (£10 shares)	100,000
Schanscheff Electric Light and Power Co. (£5 shares)	200,000

NOTES.

Meteorological Society. At the meeting to be held on Wednesday, the 18th inst., Prof. A. S. Herschel will read a paper on "Lightning in Snowstorms."

Ches Bignon.—The celebrated restaurant in the Avenue de l'Opera, so dear in every sense to epicures of all nationalities, is now lighted by incandescence lamps.

Union Bank Installation. We understand that Messrs. B. Verity and Sons were the contractors for the whole of this installation, and not merely for the fittings.

Edinburgh Public Library. Tenders are invited by the Edinburgh Municipality for the electric lighting of this library. Further particulars will be found in our advertising columns.

The Electric Light in Russia.—The theatres at Odessa and Riga have been electrically lighted by Ganz and Co., of Buda-Pesth. The central station supplying the former town is more than a kilometre and a half distant from it.

Spain.—The Government is putting up to auction the right of constructing and working telephone systems at Alcoy (province of Alicante) and at Murcia. The former concessions will be disposed of on the 27th inst., and the latter on the 13th of June.

Poplar Union.—The Guardians of the above Union invite offers for the repair and maintenance of the electric bell system at the workhouse. Application is to be made to the master of the workhouse, High street, Poplar, who will supply form of tender.

Barnet.—A draft contract has been submitted to the Barnet Local Board, by Messrs. Joel and Co., for electric lighting. After a discussion of the subject at the last meeting of the Board, and the requirement of a provisional order, the question was adjourned to a future meeting of the Board.

Verona.—The local company formed to establish a central station for electric lighting having failed to carry this project into effect, power was given to the gas company, at a general meeting of its shareholders, to take up the question of lighting by electricity, and eventually to carry the requisite work into effect.

Halifax-Bermuda Cable. As will be seen from our advertising columns, the Postmaster-General invites tenders for laying, maintaining and working a telegraph cable from Halifax (Nova Scotia) to Bermuda. The line will be subsidised by Government, whose liability or responsibility in regard to it is limited to the payment of the subsidy.

The Electric Light in Austria. Messrs. Siemens and Co., of Berlin, have undertaken the work of establishing at Quortitz a central station, disposing of 500 h.p., and supplying 1,500 lamps. The same firm have installed at Salzburg a central station, working 300 incandescence and 26 arc lamps by means of three dynamos. The price per incandescence lamp per hour is 9.2 centimes (4 kreuzers).

The Telephone at Martinique. On the 16th prox. a concession for the working of the subventioned service of electrical communication in the interior of the colony will be disposed of by auction. The system will consist: 1st, of a telegraph line between Fort-de-France and Saint-Pierre, already established, and 2nd, of a network of telephonic lines between all the communes in the island which has yet to be constructed.

An Insulation Breakdown.—After the recent snow-storm at Pittsburg, large quantities of salt were used to melt the snow on an electric tramway with underground conducting wire. The resulting solution of salt, having saturated the wooden conducts in which the conductor was laid, destroyed the insulation of the line, which was worked under an E.M.F. of 500 volts, and the whole of the wood-work was rendered useless.

Rheims. The local company for private electric lighting has been dissolved, and, as in several other instances, the work has been taken up by the gas company. At a general meeting of the shareholders of the company, full powers were given to the directors for continuing the negotiations with the town authorities on the subject of electric lighting, and provision was made for the expense to be incurred under this heading.

High Ratio of Power to Weight.—According to *Cosmos*, M. Trouvé has constructed a minute electric motor, weighing 80 grammes, and yielding a power of two kilogrammetres (about 14.5 foot-pound) per sec. Under an E.M.F. of 14 volts (*Cosmos* spells it *volts*) this little machine, provided with a fan, will raise its own weight—i.e., itself. At this rate, a motor developing one horse-power would weigh little more than three kilos.

Clermont-Ferrant. The gas company at this town has been more successful in electric lighting than has the competing local company, which until recently carried on the lighting of some private establishments. The town authorities gave the preference to the former in regard to the work of illuminating the theatre, and the gas company has expended from 30,000 to 40,000fr. in carrying out the installation, which has been a success.

Sulphur.—In its ordinary condition sulphur is one of the best insulators, i.e., one of the worst conductors known. M. Duter, in some experiments at the Sorbonne Laboratory, has, however, shown that, when raised to its boiling point (about 836deg. F.), sulphur is capable of transmitting an appreciable current of electricity. With electrodes of gold, connected to a battery of Leyden jars, a current was obtained having the mean value of $\frac{1}{2000}$ ampere.

Christchurch (New Zealand). The Council of Christchurch, New Zealand, invite tenders for lighting the city by electricity, in accordance with the specification and conditions to be seen at the office of the Agent-General for New Zealand, 7, Westminster-chambers, Victoria-street, London. Tenders to be sent direct to the Christchurch City Council, New Zealand, to arrive by the 1st July. Mr. F. T. Haskins is town clerk at the City Council Office.

Bradford.—At the meeting of the Council, held on the 10th inst., Ald. Priestman (chairman of the Gas Committee) stated that the specifications for the installation of the electric light had been prepared, and he expected tenders to be received by the 25th inst. The specifications had been very carefully prepared after making enquiries into the systems of electric lighting adopted elsewhere, so that Bradford might have the advantage of the best system.

Bristol.—The Bristol Cathedral is to be lit by electricity, and it is proposed to use such light at the grand evening service and production of Handel's oratorio, "Israel in Egypt," on Friday, June 8th, in celebration of the completion of the western towers. When the Jubilee services on a similar scale were given in the cathedral, the rows of gas jets necessary to give light to the 500 members of the

choir enclosed them with lines of such intense heat that some of the closely wedged choir had to retire.

The Society's Fire Rules.—We have received a copy of the Society of Telegraph-Engineers' rules and regulations recommended for the prevention of fire risks from electric lighting, dated April, 1888. Our opinion as to the advisability of multiplying "rules" is well known. If satisfactory, the different rules must be approximately the same in tenour—if, indeed, they are not in their verbal rendering. We regret that some way has not been found to bring the conflicting interests into agreement.

"Montagnes Russes." The Thomson Houston Company has just carried out its first installation of electric lighting in Paris. It comprises about thirty arc lamps for the new establishment of *montagnes russes* at the Boulevard des Capucines. The popular though desultory system of locomotion known by this name is analogous to the toboggan and switchback railway, the excursionist entering a car which speeds with giddy rapidity along smooth rails for a furlong or so. The electric light in such establishments is *de rigueur*.

The Fire at the Hotel de Lucerne. The disastrous fire which destroyed the Gutsch Hotel had been attributed to a Zipernowski transformer; but it now appears that the damaging accusation brought against one of the systems of electric lighting was altogether unfounded. The transformers, which were duly provided with fusible cut-outs, are proved to have been in working order whilst the fire was actually proceeding, and the presence on the roof of the hotel of a working plumber with lighted brazier appears to be the most probable cause of the conflagration.

The Electric Light at Perpignan.—The Municipality of this town are in treaty with the electric lighting company recently established there by M. Lamy for the lighting of the theatre, and for the distribution of the current to private establishments. The duration of the proposed concession is 30 years, and the price to be charged for public illumination is 2 centimes per hour per lamp of 16 c.p., or 1 centime per hour per lamp of 10 c.p. Certain fines are imposed in case of shortcomings in the due performance of the contract on the part of the company.

The Electric Light in Textile Manufactories.—M. Krettlinger, in the "Centralblatt für Elektrotechnik," points out that incandescence lighting has, with great advantage, superseded petroleum in a lace manufactory near Carlsbad, where artificial illumination is sometimes necessary for as many as eighteen hours per diem. The dynamo machine employed is from the Viennese firm of the same name as that above mentioned, and supplies 30 amperes, at a potential of 100 volts, when making 950 revolutions per minute. Another, and larger, installation is at the silkworks of Messrs. J. Adensanser and Co., at Vienna.

The Lewis Cable.—On Tuesday last, in the House of Commons, Dr. McDonald asked the Postmaster-General when it was his intention to have the telegraph cable between Lewis and the mainland, which had been out of order for several weeks, repaired; and whether, having regard to the large fishing interests of the island, which were mainly dependent for the sale of fish on telegraphic intelligence, he intended to lay a new cable instead of that now out of order. Mr. Raikes stated, in reply to the hon. member, that the cable ship belonging to the Post Office is at the present moment engaged in the repair of the Stornoway cable.

The Electric Light in Theatres.—An incident has occurred at the Madrid circus which practically illustrates the known fact that when carelessness and the neglect of obvious precautions come into play, the electric light, whilst safeguarding against the manifold dangers of gas, may actually be the means of producing a conflagration on its own account. The current traversing one of the conducting wires was so unduly strong as to set fire to its covering and to some articles in proximity to it. Happily the alarm occasioned quickly subsided, and the damage was but of small importance.

The Electric Light in Theatres.—At a recent meeting in Paris of the Superior Committee on Theatres, under the presidency of the prefect of police, it was decided that the supplementary lamps (*lampes de secours*) might be supplied by accumulators, and worked in two circuits only. On the motion of M. Duynesnel, who urged that every facility should be afforded to theatres in adopting the electric light with a view to the safety of the public, the committee recommended that an exceptional permission should be granted to them by the Prefect of the Seine to make use of the street subways in laying the mains for supplying electrical power from external central stations.

Protection of Wires.—Electric light engineers have passed by, or have not sufficiently recognised, the value of iron piping glazed in the interior for carrying their leads. If well done, the glaze is a good insulator, and, therefore, it is probable a cheaper covered wire could be used than is usually the case. We have before us a specimen of such iron piping, $\frac{1}{2}$ in. clear internal diameter, made by John Spencer, Globe Tube Works, Wednesbury, sent us at our request, as the matter had been discussed among several electrical engineers with the result of obtaining a general opinion that the material would be useful. Of course the pipes can be made to any other size that may be required. We have no information as to how the price of such piping would compare with the present methods.

The E.P.S. Accumulator in France.—Since the failure of the "Frenck" and "Metropolitan" Companies in 1884, the manufacture of Faure-Sellon-Volekmar has been discontinued. Quite recently, however, Messrs. Philippart Bros. have acquired the French patents for this battery and for the newer type of cell known as the E.P.S., and are about to commence the manufacture of this accumulator at their works, which they have established in the old Siemens' workshops in Paris. According to the *Bulletin International de l'Electricité*, Messrs. Philippart have caused the seizure in Paris of accumulators of all forms and patterns, and have commenced actions against a certain number of manufacturers. The result of these proceedings is looked forward to with a considerable amount of interest.

The Paris Municipal Council.—"According to its own showing," says the *Bulletin International de l'Electricité*, "the Council has done two things that it was particularly anxious to avoid doing: it has established a practical monopoly, and it has acted adversely to the interests of the working classes." This conclusion is based upon the decisions arrived at by the Council, firstly, in relation to the grant of concessions applicable to segments of a circle extending from the centre of the city to the fortifications, and secondly, in stipulating for the use of accumulators by concessionaires with a view to the employment of a minimum number of *ouvriers* at night. "Only the Rothchild and Edison companies," according to our contem-

porary. "could undertake the establishment of central stations having their works at Villette and at Ivry."

The Radio Micrometer. This instrument is an extremely delicate form of thermopile, consisting of a square frame made of one turn of one square centimeter, of which three sides are thin copper wire, and the fourth is a compound bar of antimony and bismuth, each piece being 5 by 5 by $\frac{1}{2}$ mm., soldered edge to edge. This frame is supported by a thin rod, to which is fastened a mirror, and the whole is hung by a torsion fibre, so that the frame is in the field produced by a powerful magnet with suitable pole pieces. When radiant energy falls on the centre of the bar the frame is deflected, and the amount of the deflection measures the energy. Adopting suitable dimensions, and using a very strong field, an instrument may be made capable of showing a change of temperature of the junction of one thousand millionth of a degree of heat.

The Krebs Electric Motor.—A motor to be worked by accumulators, intended for a submarine boat which is being constructed by M. Zede, has recently been completed by M. Krebs, who has laid before the *Académie des Sciences* the results of some experiments which have been carried out with it on *terre ferme*. The machine weighs 2,000 kilos, and will, it is stated, give a power of 52 *chevaux vapeur* when worked with a current of 200 amperes under a difference of potentials at the terminals of 192 volts. (The theoretical value of the watts is under 52 horse-power: but it must be remembered that the *force de cheval* is equivalent to 736 watts only, instead of 746). The current is supplied by 564 accumulators on the Commin, Desmasure, and Baillehache system, in which an alkaline electrolyte is employed. The total weight of these accumulators is 9,840 kilos. Arrangements have been made for connecting up the accumulators in four different ways, in order to vary the expenditure of power. The results obtained are said to verify the anticipations of the inventor.

Arthur-street East Extension.—The engineer to the Commissioners of Sewers (Colonel Haywood) refers in his annual report to the Arthur-street East extension. This street extension commences on the eastern side of the Monument, and is carried by an easy curve to the southern end of St. Mary-at-Hill, where it joins Lower Thames-street opposite to Billingsgate Market. Its length is 454ft., its width 50ft., the roadway is 33ft. wide, the footways on either side 8ft. 6in. wide, and its gradients vary from 1 in 34 to 1 in 39. At its junction with Lower Thames-street is an open space about 140ft. long and 80ft. wide. Beneath the centre of the street is a subway for gas, water, and other pipes, semicircular in form, 12ft. wide and 7ft. 6in. high. A paved footway with iron tram rails is laid throughout the subway, thus enabling pipes and materials to be readily moved by rolleys. Sleeper walls are built on each side throughout its length to support the pipes; cast-iron brackets project from the wall on each side, about 5ft. above the floor-line, for the same purpose, and provision is made for the carrying telegraph and telephone wires by hooks fixed in the crown of the subway arch.

Prices in America.—New Haven pays for 2,000 candle-power lamps, running every night and all night, 50 cents (say 2s.) per night, or 182.50dols. (£36. 10s.) each per year. Middletown pays for 2,000 candle-power lights running every night until 11.30 p.m. 100dols. (£20) each a year; for 2,000 candle-power lights running 20 days a

month 75dols. (£15) each a year, and 35 cents each per night over 20 nights a month, all lights running till 11.30 p.m. Waterbury pays for 2,000 candle-power lights running 312 nights until 1 a.m. 117dols. (£23. 8s.) each a year, and for 1,200 candle-power lights running the same hours and same number of nights 78dols. (£15 12s.) each a year. Bridgeport pays for 2,000 candle-power lights running every night all night 50 cents a night, or 182dols. 50 cents (£36 10s.) each a year. Meriden pays for every night in the year, and running until 1 a.m., 150dols. (£30) each a year. Hartford pays under present contract for 337 nights, running all night, 142dols. 51 cents (£28 10s.) for each light. Under the new contract made by the street board, it pays 117dols. 94 cents (£23 8s. 1d.) each, and gets under this new contract, as also under the present contract, 2,000 candle-power lights running all night for 337 nights, and 1,200 candle-power lights at a corresponding price, or at 78dols. 63 cents (£15 14s. 1d.) each a year.

Incandescence Lamps.—In reference to the views of Mr. Huxley, quoted in a note under this heading in our last issue, the *Electrical World* recalls the experiment of Prof. Quinke, who exhausted a glass tube and weighed it at intervals during many years without being able to detect the slightest difference in its weight by the most delicate balance. This result may be accepted as conclusive proof that no air had obtained admission to the tube in question. The contention that in the case of incandescence lamps air enters through the "pores" of the glass when the latter becomes heated, appears improbable, and has not been supported by any direct experiment. Still, it is known that hollow vessels of comparatively thick metal, when under pressure and heated, allow the passage of liquid; and it is possible that thin glass, especially of a certain quality, may, when heated, allow the passage of air. It is beyond question that, under ordinary conditions, air may find an entrance at the junction between glass and a platinum wire embedded in the same. The constituents of air would no doubt enter into combination with the carbon of the heated filament, but it is questionable whether it would have any effect in "vaporising" that element. There is really no evidence, in fact, that the blackening of the globes of incandescence lamps is due to a defective vacuum. The true cause of this effect is a question of great interest and importance, as is everything relating to the effective life of such lamps.

Porous Electrodes.—In connection with the accumulator, with a negative element (anode in charging) of porous copper, and with an alkaline electrolyte, devised by Messrs. Commin, Desmasure, and Baillehache, a series of experiments have been carried out by M. Randsept, of Brussels, with a view to determine the degree of porosity most favourable to the storage capacity of the element, due regard being paid to its mechanical permanency. The point is one of considerable practical interest, since it relates to the conditions under which a storage capacity of 8,200 kilogrammetres per kilogram of battery (26,896ft. lb. per lb.) has already been obtained, and under which this may possibly be even augmented. The copper elements in question are obtained by the powerful compression of the metal in the condition of powder or sponge; but this compression must not exceed a certain limit, beyond which the material becomes analogous to the cast metal. On the other hand, from the point of view of the electrical conductivity of the porous metal, as well as from that of its mechanical properties, it is obvious that the compression

must attain also a certain minimum limit. The determination of the maximum and minimum limits of compression may probably result from the experiments in question. M. Bandsept has experimented with pulverulent deposits electrolytically obtained on surfaces of metal, with the result that mechanical pressure may sometimes in this case be dispensed with.

Messrs. Woodhouse and Rawson.—A catalogue of domestic electrical supplies, or "ironmonger's list," has been issued by this firm, and will be found useful by the large class to whom the applications of electricity are not only of interest, but are possessed of a peculiar fascination. Such persons, wise in their generation and advancing with their times, will, for instance, be pleased with the simple and cheap forms of burglar and fire alarm illustrated on pages 8 and 9, and, being already possessed of a portable electric gas lighter, will scarcely be able to resist investing in a pocket accumulator—an acquisition leading, perhaps, ultimately to the purchase of one of the very beautiful articles of electrical jewellery, *à la Trouet*, described and illustrated at pages 47 and 48. From an educational point of view, the Student's Dynamo, which can be converted at will from a "series" to a "shunt" machine and *vice versa*, might be an excellent investment; and the purchase of one of the small electromotors, with a battery to work it, might often constitute the starting-point on the road to a considerable amount of useful knowledge in relation to electrical applications. We notice in the "battery directions" one mistake, perhaps a misprint: to charge the Fuller battery, the tyro is directed to mix pulverised *bichromate* (instead of *bichromate*) of potash with strong sulphuric acid. The result of carrying out this instruction might be so startling, if not serious, that we recommend a retrospective as well as prospective rectification of the error. At all events, no further copies should be issued without the necessary correction.

Australia.—In the Centennial Supplement to the *Sydney Morning Herald*, information is given as to the telegraphic communication in the Colonies. Of New South Wales we read that "postal and telegraphic facilities also exist in every direction. Within the last few years the advantages of the telephone have been added to those of the telegraph, and though telephonic communication as yet only exists between the business houses in town, it is hoped that ere long the towns may be linked together telephonically as they are telegraphically." Of Victoria, the statistics give the number of telegraph stations as 420; miles of line, 4,094; miles of wire, 10,111; telegrams received and despatched, 1,938,049. South Australia is said "in telegraphic enterprise to have had the honour of carrying out, at immense cost, a transcontinental line from Adelaide to Port Darwin, a length of 1,973 miles, thus connecting the Colonies with the telegraphic system of the world. This great work was commenced in August, 1870, with an estimate of £120,000 for expenditure, and completed in the face of the most baffling difficulties just two years later at an actual cost of £370,000. The first message delivered from London by this wire reached Adelaide on June 20, 1872, and the usual time of transit is about six hours. A Telephone Exchange exists in Adelaide, with 1,539 miles of wire. Queensland has 282 telegraph stations, 9,004 miles of line, and 14,443 miles of wire. The returns of Western Australia show 2,885 miles of line. Tasmania has 144 telegraph stations, while New Zealand has 330 stations, with 4,546 miles of line, having 11,178 miles of wire included in

this length are 359 miles of cable, while 79 miles of cable are under construction.

Hydrogen Peroxide.—The question of the electrolytic formation of hydrogen peroxide at the anode has been investigated by M. Traube. From the results of previous experiments it was concluded that hydrogen peroxide is formed by the union of molecular oxygen with hydrogen. Richarz, on the other hand, maintains that hydrogen peroxide is produced by the oxidation of water. When 1 per cent. sulphuric acid is electrolysed in presence of alcohol or hydrogen peroxide at the anode, these are rapidly oxidised. In the electrolysis of a 1 per cent. solution of chrome alum, not a trace of ozone is formed, and chromic acid appears at the anode. When lead is used as anode in the electrolysis of 1 per cent. sulphuric acid, it becomes covered with lead peroxide. These experiments point to the presence of free oxygen-atoms which only unite to passive molecules when there is nothing to oxidise, and also show that water is not oxidised by oxygen-atoms. In the electrolysis of sulphuric acid, it is suggested that per sulphuric acid is formed by the action of nascent oxygen, and that this decomposes into sulphuric acid (2 mols.) and hydrogen peroxide (1 mol.) As further proof in favour of the constitution previously ascribed to hydrogen peroxide, it is mentioned that the peroxides of hydrogen, of the alkalis and alkaline earths, of zinc, cadmium, and copper, have quite different chemical properties from those of lead, silver, manganese, and nickel, &c. Only those of the first group yield hydrogen peroxide when treated with acids. The peroxides of the second group can all be prepared by

oxidising the ~~oxalates~~ *oxalates* or hydroxides in alkaline solution. The peroxides of the first group possess powerful reducing properties, whilst those of the second group are indifferent to oxidising agents. Hence it is concluded that the peroxides of the two groups are differently constituted, and that hydrogen peroxides cannot have the formula $\text{HO}\cdot\text{OH}$. The constitution represented by the formula $\text{H}\cdot\text{O}:\text{O}\cdot\text{H}$ is considered to be the only one possible.

The Electric Light in Florida.—According to a correspondent of the *Scientific American*, Mr. H. M. Flagler has installed in the Hotel Ponce de Leon, at St. Augustine, the largest isolated (private) plant for supplying electricity which exists in that country, or, in fact, throughout the world. The installation consists of four Babcock and Wilcox multitubular boilers, each of which has a nominal rating of 107 h.p.; four Armstrong and Sims engines, three of 60 h.p. and one of 125. Each of the 60 h.p. engines drives an Edison dynamo of the latest type, having a capacity of 64 sixteen-candle lights. The other engine drives two machines of the No. 16 type. The rating given is nominal, as the plant admits of an increase in power of 25 per cent. over and above the rating. It is doubtful if there exists another electric light plant with so perfect a system of control and regulation. Each dynamo has its own regulator, which controls the amount of electricity produced, and indicator showing the volume and pressure of the electricity. The machines are all connected to heavy bars of soft copper, termed "omnibus wires," with which, by switch in the headboard of the machines, they may constantly be connected or disconnected. To the "omnibus wires" are connected a series of heavy copper cables, called "feeders," which pass to the most important centres of lighting in the Hotels Ponce de Leon and Alcazar. No lamps are directly connected to these "feeders," but they carry the current to the local distributing points, from which a large number of

ller wires, "mains," lead the electricity to the "series." These, in turn, conduct it directly to the lamps in the buildings. Danger from fire by this system the danger is reduced practically to nil. At the junctions of the "bus wires," "feeders," and "mains," are fitted fuses, composed of an alloy of lead and tin, which volatilises at a temperature of 400deg. If by any accident the copper wires conducting the electric current should come in contact with each other, before the temperature of the copper could be raised sufficiently to set fire to any inflammable substance in proximity to it, the safety fuse would vaporise and open the circuit. Soon as the trouble had been rectified, a fresh fusing wire would be inserted, and the current re-established in the circuit. Nor is there any danger to human life from coming into contact with the wires or machinery of the system. The pressure is only of about 100 volts, which a child can receive with impunity. This plant supplies the lights used in the Hotels Ponce de Leon and Alcazar with all about 5,500 incandescent lamps.

Electrical Lighting of Steamships.—The steamship "Paula," built for the petroleum trade by Sir W. G. Armstrong, Mitchell & Co., at Low Walker, has a complete installation of electric light, by Mr. Rankin Kennedy, of Rodside Electric Works, Glasgow. The dynamo is one of Mr. Kennedy's single-bobbin machines, capable of supplying electricity for 70 sixteen candle-power lamps, and running at a speed of 750 revolutions per minute. This machine runs entirely without sparking at the brushes, giving a much longer life for the commutator and brushes, which are the principal wearing parts in electric generating apparatus. The machine is neatly designed, compactly arranged; every detail of brush arrangement and general construction has had careful attention, and it seems to embody in a high degree of perfection the many improvements which have from time to time been made in the construction of dynamo machinery. The motive power is derived from a Tangye's "Archer" type steam engine, and is communicated to the dynamo by means of a canvas and gutta-percha belt from the fly-wheel to the dynamo pulley. The governing arrangements for regulation of the machine are so complete that the difference in electromotive force in the circuits is less than 1 per cent., with full load and one lamp respectively. Passing from the generating apparatus, a special feature of the installation is the wiring. In the whole ship, with the exception of the saloon and officers' quarters, specially protected conductors, consisting of copper wires insulated with vulcanised indiarubber, and sheathed over all with galvanised iron wires, are used. The joints in these conductors are protected by specially designed malleable cast-iron joint-boxes, and the whole arrangement makes a very substantial job, calculated to withstand any amount of rough usage without injury. This is of the greatest importance in petroleum-carrying vessels, where the conductors require to be specially secure on account of the nature of the cargo. The fittings in the saloon and the cabins are of the same design, in harmony with other fittings of the ship, and here, as in every other part of the ship, every fitting has its own separate switch, and can be turned on or off as desired. The globes in this part of the ship are of pale pearl, and give a particularly pleasing effect to the light. Throughout the whole ship, wherever light is required, the electric light has been carried, and arrangements are also made, and portable lamps with long

flexible leads provided, for carrying the light down into the tanks when they require cleaning out or inspecting. The masthead, side, and anchor lamps have also been arranged for electric light. We understand that the same firm are engaged fitting out the "Caucase," another vessel for the same trade (recently launched by the same builders), and that they are putting electric light on two passenger steamers for the Chinese coasting trade, building at Messrs. Hawthorn, Leslie and Co.'s.

Electric Lighting of Trains.—Mr W. W. Ackworth in the current number of *Murray's Magazine* contributes an article on the Great Northern, North Eastern, and Manchester, Sheffield, and Lancashire Railways. In this article he describes a great many interesting topics, but, so far as the electric light engineer is concerned, the most interesting will be found in the concluding paragraphs of the article, which refer to the electric lighting of carriages. He describes the system in use by the North British at Glasgow, where, as is well known to our readers, a third wire is laid through the tunnels, and the train is lighted while going through the tunnels. Mr. Ackworth says of lighting by means of accumulators, that they are expensive and heavy, that the cost for charging is great, and the superintendent is hampered by a perpetual feeling of hesitation whether the supply will last till the train has completed its journey. He discusses then the mounting of the dynamo upon the train, and refers to the experiment made by the Lancashire and Yorkshire and Great Eastern with a retort engine—which plan, not being found to answer, was abandoned, though the North-Western has two trains running between Liverpool and Manchester lighted on a somewhat similar system. In this case, if there is a change of engines, unless the new engine carries a dynamo, the light is useless. If, says the author, on the other hand, you can put your dynamo on the train and drive it from the carriage wheels, you are independent of the engine altogether. The Great Northern has five trains so fitted. The author thus describes the Great Northern arrangement for running the dynamo: "We may note, to start with, that unless the passengers are content to sit in darkness every time the train stops, it is impossible to dispense with accumulators altogether. Further, a carriage runs now one end forward and now the other, and the ordinary dynamo must always be driven the one way. This difficulty is in the Great Northern installation got over by an ingenious arrangement of automatic reversing gear. Again, the accumulators are charged from the dynamo. But an accumulator is, so to speak, like a tank of water on a high tower. If the engineer were to connect his pumps with the bottom of the tank, when the power of the engine was insufficient to overcome the downward pressure of the water stored in it, instead of filling the tank, he would only have provided an outlet for its contents. So with the dynamo. Unless it is running about 450 revolutions a minute—in other words, unless the train is going 15 miles an hour (for the dynamo makes five revolutions for each revolution of the carriage axle) it is not producing sufficient electricity to overbalance that already stored up. Accordingly, what is known as a resistance coil is provided, through which the electricity is diverted when the train first starts. As soon as it has reached a sufficient speed an automatic switch cuts out the resistance coil and switches the accumulators into the circuit, to be again cut out automatically as soon as the speed of the train slackens again."

CENTRAL STATION LIGHTING—TRANSFORMERS v. ACCUMULATORS.*

BY H. K. CROMPTON, MEMBER.

The present paper is the outcome of the discussion which took place on Messrs. Kapp's and Mackenzie's papers on transformers, recently read before this society. I was asked to give facts and figures in support of the statement I then made, that I believed the distribution of electricity by transformers offered no special advantages over other methods, particularly over distribution by means of accumulators used as transformers.

However, after compiling the statement of facts and figures necessary for my purpose, I found that I had undertaken a task of a much heavier nature than I originally intended; and I must apologise for the present paper having a much wider scope than its title would warrant.

In fact, I find it necessary to commence by discussing some of the conditions of the supply of electricity from electric stations which are common to all systems of distribution, and about which little or nothing has hitherto been written or said. In England, central station lighting has been such an affair of yesterday, that it is hardly to be wondered that what little knowledge exists on the subject should be confined to the few who have lighting stations under their immediate charge; and when we look to the Continent, or to America, to supplement this meagre stock of knowledge, we find the conditions of demand for light differ from those of a large English town, such as London, so that they do not much help us in our investigation. However, during the past few years I have done my best to make myself acquainted with the main facts which appear likely to govern the future commercial success of such undertakings.

I must at once divide the schemes for electric supply into two classes. 1st, those confessedly carried out in a temporary manner, and for the purpose of popularising the electric light, and inspiring the confidence of the public in supply companies as a form of investment; and, 2ndly, those intended to be of as permanent a nature as the gas supply with which they come into competition. I think to the first class we must relegate such systems of supply as those at Brighton, Eastbourne, the present supply from the Grosvenor Gallery; in fact, all those which distribute by means of overhead wires, picking their customers here and there, and which, although they have served a very useful turn in familiarising the public with the use of the electric light, cannot be considered as in any sense fitted to develop themselves into a complete system of supply when the time arrives that more than half the houses may be expected to take the light.

In order to get an adequate idea of the nature of the demand, or what I call the load diagram of a system of supply, we cannot do better than refer to the diagrams of a similar nature taken by the gas companies. Having recently had the advantage of carrying out electric supply stations for several gas companies, I have had access to such load diagrams for gas lighting, and from these and from the experience already obtained of electric supply in London, I have constructed a load diagram which I believe will be found a fairly representative one for an ordinary London residential district, consisting partly of private houses, partly of shops, with the usual sprinkling of hotels and public buildings. No doubt a district containing a very large number of theatres would have a somewhat different diagram, but not differing so much as to materially affect the arguments that I am about to found on these load diagrams. Through the kindness of Dr. Fleming, I am able to lay before you several load diagrams obtained from lighting stations in America, which, you see, coincide very fairly with the one I have prepared for London. We learn from these load diagrams, 1st, that the average daily outputs in units throughout the year is about three and a half times the maximum load in kilo-watts; in other words, that a station having a plant equal to the supply of 600 kilo-watts—that is to say, 10,000 lamps of 16 candle-power each simultaneously alight—could only calculate on selling an average quantity of 2,100 units per day. This

fact, which has such an important bearing on the possible profits to be obtained from a station of a given size, appears to have been completely ignored by the writer of an article on central stations in *Industries*, dated the 2nd December, 1887, who estimates that a plant of this size would be able to supply daily 3,600 Board of Trade units, which is 73 per cent in excess of the figure I have given above. The next point we have to note, common to all systems of distribution, is the extent of underground mains necessary to distribute a given supply of electricity, and the probable cost of such mains when laid underneath the footways of our streets. Starting once more on the above quoted 10,000 light plant basis, I find, from careful note of the amount of electricity used by various classes of houses, that in order to sell an average of 2,100 units per day our distributing mains must reach not less than 1,000 houses. We may take the average width of the London house at 10 yards, to this we must add 50 per cent., on the supposition that only two houses out of three will take the light for some time to come; and to this we must again add 30 per cent. for such proportions of the roads, such as crossings, dead walls, &c., traversed by the mains, which do not front houses taking the light. We thus find that every house requires twenty yards of distributing main; or to distribute the daily average supply of 2,100 units, 20,000 yards of main. In addition to these distributing mains, we must contemplate the probability of the generating station being placed at a distance of 2,000 yards from the centre of the district supplied, so that in all we have to provide 22,000 yards of mains of the two classes of mains. For convenience of nomenclature, I call those mains which form the primary wire to the transformers, or carry the charging current to the accumulators, 'charging mains', and those from the transformers to the houses, or from the accumulators to the houses, 'distributing mains.' Next, as to the cost of these mains, I have prepared two tables, which show how wide of the mark is the popular idea that the cost of the mains is greatly influenced by the cost of the copper conductors themselves. I have stated at this institution that much nonsense has been talked on the subject of the cost of copper; by this I did not intend to be disrespectful to any particular speaker, but to point out in strong language that the habit of basing estimates of distribution on the cost of copper (with but a small percentage added for insulation and laying) was one to be avoided, as it has led to erroneous conclusions, on which have been based arguments far too favourable to systems using currents of high E.M.F.

No doubt this habit of considering the cost of copper as such an important element in the calculation has arisen from the fact that, although this question of electrical distribution has been for years under discussion, and has had volumes written about it, yet our experience in laying and repairing such conductors has been until quite recently almost nil. The tables now before you are based on the little experience that I have gained during the last three years, and I trust they may be of some service to the members of the institution. Many of the figures are the actual prices paid out on executed contracts, and the other ones are calculated from them; so that it is quite certain that the figures quoted in the table are not far wide of the mark. You will notice that, apart from the price of the copper itself, the additions we have had to make for the insulation, troughing, cost of laying, providing and fixing surface boxes, digging and guarding the trenches, taking up and replacing the flagging and wood pavements, are almost a constant quantity depending only on the length of the roadway that is disturbed, and, consequently, when considered in relation to the cost of copper itself, are at a maximum when the section of the copper is small and decrease rapidly as the section augments.

Table I. is for laying copper in the form of insulated cables in the old and well-tried way. Table II. is for a form of main which I have successfully adopted during the past year, and which consists of a bare copper conductor, supported and insulated in concrete subways or culverts by porcelain insulators. I am not at present submitting the latter system for your criticism. In some respects it is not yet perfect; but I mention it as I am employing it to a

* Paper read before the Society of Telegraph Engineers and Electricians, on Thursday, April 12th, 1888.

considerable extent myself, and believe that it will prove a very valuable form of conductor for whatever system of distribution is used. The completed main consists of such very durable materials, and the facilities for repairs and renewals, or for increase in the section of the conductor are so great, that the annual charge for the upkeep and depreciation of these mains is not likely to exceed 25 per cent. of that of the older form of cables insulated with the continuous covering, whatever material may be employed for that covering.

With these considerations of the load diagrams, the extent of distributing system, and the cost of the mains before us, we can now proceed to compare the merits of distributing the electricity by two systems—the first being by alternating currents of high E.M.F., transformed to currents of low E.M.F., suitable to the glow and arc lamps used by the consumers, and which I hereafter call the A.T. system; and second, the supply by means of direct currents of medium E.M.F. used to charge accumulators arranged in series, the current being taken off the accumulators at the lower E.M.F. required for the lamps, and which I hereafter call the B.T. system.

All modern systems of distribution aim at the reduction of the first cost of the distributing plant—that is, of the charging and distributing mains, and all appliances belonging to them, such as transformers, regulating devices, street surface boxes, house connections, &c., providing that such reductions shall not be at the expense of the efficiency of the system. It is difficult to fix an exact percentage of the loss allowable in the distributing plant, as so much depends on the length of the working hours; but I take it for granted that in no case must this loss exceed 10 per cent. I further take it for granted that the extreme variation allowable in the E.M.F. in the distributing mains must not exceed 4 per cent. So much has recently been written on the A.T. system that I will not lengthen this paper by describing it further than by stating that for purposes of my comparison I take the system as generally described by Mr. Kapp in his paper on transformers; or by Mr. Mackenzie in his paper on transformers; and in an article in *Industries*, dated December 2nd, 1887, for which I believe Mr. Kapp is responsible, and which gives very complete data on the first cost of an installation for 10,000 60-watt lamps, burnt simultaneously. On the other hand, it is necessary for me here to briefly explain the B.T. system, which I propose to compare with it.

At Vienna, the arrangements proposed by Mr. Monnier, and successfully carried out by myself and others, consist of charging from a central station groups of batteries of accumulators arranged in series. Each group of accumulators consists of 52 cells, giving the 100 volts required for the lamps, with a comfortable margin. The total E.M.F. required to charge the four groups of batteries in series varies from 430 volts, at the time the batteries are giving off work, to 480 volts, for the short time during which the charge is being completed. This includes the loss in the mains, generating stations being situated 1,400 yards from the distributing station. During five hours of lighting about two-thirds of the current comes direct from the dynamos; but during this time for short periods the demand of current often increases to such an extent that these proportions may be reversed, and the batteries supply two thirds of the total. As this system has now been in use for upwards of nine months without any hitch or trouble whatever in connection with the electrical work, we may consider it proved there is no danger or difficulty in using currents of such high E.M.F. as 480 volts connected permanently to the distributing mains. The system may, of course, be united with three or two groups only in series. An example of the last is the central station belonging to the Lemans Gas Company.

I now propose to commence my comparison of the two systems from four points of view: 1st, as to trustworthiness, steadiness, and quality of the lighting; 2nd, as to first cost of the plant; and 3rd, as to working cost and maintenance; 4th, as to the probable output, and hence maximum income, that can be safely obtained from the sale of electricity in each case.

I think it will be allowed that the commercial success of an electric light undertaking depends on these four points.

I do not propose to dwell much on the first point. It is generally admitted that a system which uses storage must be superior to a system in which the continuity of the lighting depends entirely on moving machinery. There are many reasons why I should not make invidious comparisons on these points between existing systems. No one is prepared to dispute the facts that the A.T. systems hitherto installed have been remarkable for frequent interruptions in the lighting, whereas the reverse has been the case with the B.T. system. It remains for us to consider whether the undoubted great advantages which the B.T. system possesses in this respect is not purchased too dearly; and this matter will occupy the remainder of my paper. The comparison I now make is for a system of electrical supply for London for 10,000 60 watt lamps, or their equivalent, simultaneously alight at hours of maximum demand: 1st, by alternating currents reduced from 2,000 volts to 60 volts by transformers; 2nd, by direct currents reduced from 440 volts to 110 volts by accumulators used as transformers.

Cost of Generating Station. For the A.T. system I adopt the figures given by the writer in *Industries*, on page 600, of the 2nd December, 1887. He therein proposes to provide for the 10,000 lamp plant dynamo power, including reserve equal to 865 kilo-watts, and he fixes the price of these as £5,540. As regards motive power, I do not propose to take advantage of the writer's far too liberal estimate of its cost at £12 per I.H.P., but take it at the lower figure of £8 12s per I.H.P., thus reducing the cost to £12,500. I have estimated the cost of the building, chimney stack, water tanks, connections for water, drains, all measuring instruments, and other accessories, at £11,000, thus bringing the total cost of the generating station of the A.T. system to £29,040. For the B.T. system I propose to provide plant of exactly similar type to that I have already supplied to Vienna. As I have said before, I propose that the dynamos should supply two-thirds of the maximum net output of 600 kilo-watts. We therefore require about 448 kilo-watts at the terminals of the accumulators; or, adding an 8½ per cent loss in the charging mains, 490 kilo-watts in the generating station, 20 per cent. of reserve power will bring this up to 600 kilo-watts equal to 1,000 I.H.P. Such a plant may be conveniently divided into six sets of combined engines and dynamos each of 100 kilo-watts. Adopting the figure given above viz., £8 12s. per I.H.P., at the cost of the motive power and that given by the writer in *Industries* at £8 per kilo-watt, or £4,800 for the six sets of dynamos, and estimating that the cost of the building and other accessories as before detailed, for the A.T. system will, in this case, be only £8,000 we find that £21,500 is the cost of the generating station for the B.T. system.

The cost of the alternating transformers is a very difficult matter to arrive at. The Grosvenor Gallery Company, believe, with few exceptions, supplies every consumer with his own transformer; but Mr. Kapp, in his recent paper proposes to lay down a network of mains of much the same character as I use for the B.T. system, and to supply the network by a certain number of larger transformers, placed at frequent intervals in the network. It is difficult to see how any saving can be made by this arrangement. It will be noticed that, although it reduces the number of transformers, it introduces a new element of expense and difficulty, and that is, the providing of places to fix these large transformers. It may be that such places can easily be found, but my experience has been otherwise. It is not easy to find a place for any piece of machinery of a size between that which can conveniently be got into a surface-box placed in the pavement not exceeding 1ft. in depth by 2ft. square, and a sub-station of the size I require for my battery transformer. In most cases there is no space either under the footways or under the street itself to form a water-tight chamber of sufficient cubic capacity for the purpose. Another difficulty and cause of additional expense, which I think would tend to counterbalance any saving from the decreased number of transformers, would be that the charging mains laid to the transformers, and the distributing mains away from the transformers, would have to be laid in the same trench or culvert, and this would be no small source of danger to those at work connecting houses on to the distri-

bating mains. As I have not been able to obtain any reliable data on this modified system of Mr. Kapps, I am obliged for the present to return to the system using one transformer for every two houses, and I think, for the reasons I have given above, the advocates of the A.T. system will not be able to make any great saving by adopting Mr. Kapp's suggestion.

Accumulators, to be used as transformers, must be of sufficient capacity to supply 200 kilo-watts per hour for the hours during which the demand exceeds the 100 kilo-watts supplied by the dynamos. The load curves, shown on the diagram hanging before you, show that this period of maximum supply varies from about two hours in summer to four in winter. If I provide four groups of accumulators, each of which has a total capacity of 250 kilo-watts, or 1,000 kilo-watts for the four, I provide for five hours of extreme demand, which is a condition of things extremely unlikely to occur, even in times of a fog. For it must be noted that the demand for light during a fog in the daytime (in a district partly residential and partly supplying shops) is of a far lighter nature than the demand from the same district during the ordinary hours of maximum lighting; the reason being that, during the hours of maximum lighting, not only the lamps in the basement passages and a certain portion of the dwelling rooms require to be simultaneously alight, but all upstairs passages and a certain proportion of the bed rooms also require light. This is not the case during a fog; only the basement, lower passages, and living rooms take the light, and these to not nearly the same extent as they do in the evening. In order to meet a case of possible interruptions to the charging current which might take place at the time of maximum demand, we require these accumulators to be capable of being discharged without damage to themselves, and at a fair rate of efficiency, at a rate not less than 650 kilo-watts. It is this latter requirement that has so long delayed the introduction of accumulators as transformers. Up to a recent date far too much attention has been paid to the capacity, and too little to the rate of possible maximum discharge. This state of things has lately been remedied, and I am told there are several makers of accumulators who can supply them to fulfil the above-mentioned conditions, and at the reasonable price named by me in my estimate. It must be remembered that such accidental stoppages of the lighting current as are likely to take place would not probably last for more than a few minutes—that is to say, if due provision has been made for spare machinery, and if the arrangements for working the machines parallel and interchangeable have been properly carried out. Time will not permit me in the course of this paper to describe fully the switch board and regulating arrangements necessary for the B.T. system. These require to be so arranged that the loss due to the difference of E.M.F. between the charge and discharge of the batteries may be as small as possible. It is quite possible to work the batteries parallel to the charging current during the hours of maximum demand with little or no loss from this cause, the loss being confined to the hours when the batteries are being finally filled up before the engines are stopped. The sub-stations, which contain the accumulator transformers, can in almost every case be placed on "mews" property; and I have ascertained from accurate inquiry that there is no difficulty in obtaining accommodation for them in such property, with but few exceptions, within 300 yards radius of the houses to be supplied. In each case the sub-station consists of a battery-room and living-room for the man in charge. The plant in each sub-station consists of the batteries themselves, the regulating appliances above mentioned, voltmeters, and district meters as may be thought necessary.

Distribution.—In the case of the A.T. system the charging mains, as far as they lie within the area of supply, are in reality the distributing mains; in other words, we require 20,000 yards of distributing mains to reach the houses. I am informed that the section usually employed for the distributing mains of these 2,000-volt circuits, when the transformers are placed in parallel, is 50 millimetres cross section, or 19 strand, No. 15 B.W.G. From Table No. I you will see that this costs £71 7s. per 100 yards. I have not worked out the cost of so small a section laid on my own

plan in the culverts, but it would certainly not be less than £96 per 100 yards. However, adopting the lower figure, the distributing main will cost £14,270. The writer in *Industries* says that 720 kilo-watts will have to be generated at the generating station for transmission to the area of supply; dividing this by 2,000 volts, we get 360 amperes as the current in the charging main. Adopting Professor Forbes' tables for calculating the section of the conductor, we find that it ought to be about 645 millimetres, and if laid in the cable form, as in Table I., but without surface boxes, would cost about £308 per 100 yards, or in all £6,160. It will be asked why I do not give to these charging mains the advantage of the somewhat lower cost of laying them as bare copper, as in Table II.; but I do not think it would be safe to leave conductors carrying currents at 2,000 volts thus unprotected in the culverts, as the risk to workmen employed on the district system would be too great, to which must be added the great risk to the consumers of making an accidental contact from the charging to the distributing mains. I should here remark that the very confident tone adopted by many supporters of the A.T. system rests on very slender foundations; they appear to forget that the great success obtained in America has been with overhead wires used as the primary or charging mains. We all know what a high degree of insulation is possible with overhead wires; we also know that extreme difficulty has been met with in America in all attempts to obtain sufficient insulation for wires carrying currents of high E.M.F. when laid underground. As a matter of fact, failure has been the rule, and success the exception. I believe that the difficulties of the A.T. system will commence when the contractors have to guarantee a perfect insulation with underground cables carrying currents at an E.M.F. of 2,000 volts. Let those who think otherwise read Prof. Elihu Thomson's remarks at the recent electric light convention in America. He used the following words: "Distribution of current to groups of incandescent lamps, or light, or other high potential lines should always be undertaken with great care; and it is thought that such work should only be undertaken when exceptionally favourable conditions for avoiding accidental leakages exist, especially should the potential of the line at the dynamo exceed 1,500 volts, or an amount which would sustain 30 arc lamps in series. One of the important elements of safety in such installations is simplicity and ease of inspection of the wiring, and no concealed wires should be used in them." Again he says: "For house to house and general incandescent lighting, where the distances from the station are not too great, the direct low potential systems possess most of the advantages, the difficulties of leakage from the defective insulation being of course at a minimum; but where the distances are so great as to make the required outlay for copper in the conductors practically prohibit the extension of the system, a transformer or converter system, if of good design and economy, may be made to yield excellent results." Now, the writer of these words is one of the greatest authorities on electric lighting matters in America, and a strong supporter of the A.T. system. I think, therefore, that I have not dwelt too strongly on the grave difficulties likely to be encountered by those who so glibly talk of laying underground charging mains, carrying currents at 2,000 volts potential, and I think that in all probability the additional precautions that will have to be taken to avoid failure of the insulation will be so expensive as to bring the total cost of the 22,000 yards up to practically the same sum as is required for the 2,000 yards of charging main and 20,000 yards of distributing mains of the B.T. system, for which no such special precautions are necessary.

I work out the cost of the latter as follows—I use throughout bare copper mains of 25in. section for the distributing mains—that is to say, for the 20,000 yards, at the rate given in Table II. of £100. 12s. 6d. per 100 yards, they will cost £20,125. The charging main will have to carry 910 amperes, and the extreme loss allowable being 8.25 per cent, its resistance must be 0.04 ohms. The double conductor will weigh about 45 tons; this can be laid, as in Table II., in brickwork, in cement culvert, at the rate of £306. 17s. 6d. per 100 yards, or £5,137. 10s

I have put down an item of £500 for the regulating gear for the A.T. system, and another one of £2,500 for the regulating gear for the B.T. system. The totals thus arrived at, and which you see before you on the wall, are £57,440 as the total cost of the A.T. system, and £59,762 for the B.T. system. These figures appear high; but I cannot see how they can be reduced, unless under very exceptional circumstances. In both cases a very large portion of the cost lies in the distributing plant; and of this, as you will gather from my Tables I. and II., the copper plays but an insignificant part, the real heavy charges being those inseparably connected with underground cables viz., the cost of insulation and those connected with disturbing and replacing the surface of the streets.

Comparison of working and cost of maintenance, coal bill of the A.T. system. The generating plant on the A.T. system has to run continuously—that is to say, that the larger engines will be run for an average of three hours per day; and if it be found practically possible to subdivide the plant into a number of engines, and work them parallel, as is the case with the direct current system, we may be able to credit the engines and dynamos with an efficiency of 75 per cent during these hours. In order to meet the average demand of 2,100 units per day, the load diagrams show that they will vary during these hours from 100 to 720 kilo-watts. We have as yet been furnished with no actual data as to the actual efficiency of the alternating transformer system at various rates of output, that is, the E.H.P. actually delivered to the lamps, divided by the E.H.P. at the terminals of the dynamos. It must be recollected that as the transformers must be large enough to supply the maximum demand of each house, whereas the maximum demand that the station can supply is probably not more than one-third of this, the transformers during this period of three hours cannot be more than one-third loaded, and therefore it is not probable that their efficiency is more than 70 per cent. It follows that, during the hours when the plant is working at 500, 400, and 300 kilo-watts, the total efficiency—that is, E.H.P. delivered at the lamps, divided by the E.H.P. in the engine cylinders, including loss in mains—will not be above 54 per cent. Supposing that the steam engines can work at 21 lb. of coal per I.H.P., the net quantity required per E.H.P. will be 4.65 lb., or 6.2 lb. per kilo-watt. The output during these hours may be considered as 60 per cent. of that of the whole day, or, say, 1,260 kilo-watts; therefore about 70 wt. will be used during these three hours. During the remainder of the 21 hours the transformers will be working at a very small rate of output. It is probable that their efficiency will be reduced to 30 per cent., and the efficiency of the steam engines and dynamos to 50 per cent., or a total efficiency—that is, E.H.P. at the lamps, divided by the E.H.P. of the engines—of 15 per cent. only; therefore, during this period it seems probable that 17 lb. of coal will be used per E.H.P. or 22.5 per kilo-watt. Therefore, the coal used in producing the balance of the daily output of 840 kilo-watts will be about 8 tons 8 cwt., or, making a small allowance for the lighting up of boilers, 12 tons per day. The oil, water, and petty stores may be calculated at 7s. 6d. per hour for three hours during the day, and at 1s. per hour during the remainder of the time. Therefore, the total cost of material used in running this station will be £4,849. The B.T. system, on the other hand, will show great saving on this. For the output of 2,100 units it will be sufficient to work the generating plant for about five hours at approximately its greatest rate of efficiency. I have had ample experience with this class of plant, and know that we can in actual practice produce the E.H.P. at the terminals of the dynamo with the expenditure of 31 lb. of coal. Taking the maximum loss in the accumulators, the efficiency of the system—that is, the E.H.P. at the lamps, divided by E.H.P. at the terminals of the dynamo—will be not less than 80 per cent.; therefore, we may say that each unit at the lamps can be produced for 5.75 lb. of coal, or 5 tons 8 cwt. per day, or allowing a 25 per cent margin for contingencies, 2,550 tons per annum. The water and petty stores may in this case be taken at 5s. an hour for 1,400 hours; the total cost of the material for producing 2,100 units by the B.T. system will be £2,517, or only about 57

per cent. of the cost of material by the A.T. system. Turning now to the labour in the engine room, the table before you shows that, as in the case of the A.T. system, the hours are continuous; three shifts of men will be required—it is necessary to have two foremen, six engine drivers, and nine firemen, whereas in the B.T. system there is only one shift of men: one foreman, four drivers, and three firemen are employed. I have only estimated for two extra men in the engine room for the A.T. system, but for the B.T. system I have allowed for four accumulator foremen in charge of the four accumulator stations, and two messengers. The totals thus arrived at for labour for working the systems are £1,389 8s. 8d. for the A.T. system and £975 for the B.T. system. The salaries are £1,200 for the A.T., and £1,020 for the B.T. system. The last item we come to is one for repair and renewals. In both cases I have allowed at the rate of 10 per cent. on the motive power of engines and dynamos, 5 per cent. on the buildings and fittings, 10 per cent. on transformers, 15 per cent. on accumulators, 7½ per cent. on the insulated mains that have to carry 2,000 volts, 2½ per cent. only on the bare copper mains (the majority of which only have to carry 110 volts) 10 per cent. on all regulating appliances. Thus, nearly the heaviest item, the maintenance, comes to £4,683 5s. in the A.T. system, and £4,086 10s. for the B.T. system. The gross cost of producing 776,500 units by the A.T. system would be £11,939. 13s., and the B.T. system would be £8,598. 10s., or 3.75 and 2.7 per unit respectively. In order to make a fair comparison between the two plants when worked in the most economical manner, if the generating station of the B.T. system is worked longer hours, it can actually produce the daily average of 3,600 units named by the writer in *Industries*: in order to do this the sole increase in the working expenses would be in the materials, to which £1,800 would have to be added. The cost, then, of 1,314,000 units would be £10,398. 10s., or 1.9 per unit by the B.T. system.

It will be seen, therefore, that while by both systems there is a probability of a fair return on the capital expenditure, yet in almost every respect the B.T. system is a more economical one. This arises from the fact that the main cause of expense in the A.T. system, depending, as it does, on continually moving machinery, is the heavy cost of material, labour, and superintendence during the long hours in which the machinery is working very lightly loaded. The B.T. system shows very favourably in this respect, as even at the latter increased output of 3,600 units per day the machinery need not work, on the average, more than ten hours, so that one shift of men can do the work, and there is ample time for repair and inspection of the machinery.

LITERATURE.

Management of Accumulators and Private Electric Light Installations: A Practical Handbook By Sir DAVID SALOMON, Bart. Third edition, revised and enlarged. Whittaker and Co. 1888.

We understand that so great has been the demand for this book, that a fourth edition is in preparation. For readable, trustworthy, practical books there is plenty of room, while it would be better, both for pure and applied science, if a fair proportion of the so-called school and text books were burnt by the common hangman. Sir David Salomons has provided a work of the former kind—in fact, the only work of its kind—and the information given is all the more valuable in that it is almost entirely the outcome of practical observation. It is not the first time in the annals of applied science that wealthy amateurs have done what those professionally engaged have either been unable or unwilling to do. From the first introduction of electric lighting Sir David Salomons has been experimenting to obtain a complete and satisfactory installation at his residence, Broomhall. Hence he is able to say, "The contents of this little book is the result of years of labour regardless of expense, so as to ensure results of a satisfactory nature, which are only possible by conducting endless experiments."

The great value of such a book as this is that it does not pretend to be written from the sublime heights of science. We do not read between the lines the assertion that "I am the only true prophet." Far better would it be if more books had as many grammatical errors and as much common-sense information. The man who has to look after accumulators wants to know in the simplest manner what to expect, and if anything goes wrong how to put it right, and this is just what Sir David Salomon tells him. It may be well to let the author speak for himself, or, as Old Humphrey would have said, "let us sample him." Here are a few "dots," p. 62. "Never add concentrated acid to the cells, the grids will soon become rotten if this is done. Never test if E.M.F. exists in the cell by "flashing," which means taking a short wire, placing one end firmly on the positive strip of a cell and rapidly touching the negative strip, giving in this way a flash if the cell is right. It is the old method of testing, which soon spoils the cells if

mechanical engineering, leads sooner or later to the construction of special machines to decrease the cost of manufacture. This is the case as regards the construction of dynamos. In their early days the winding of the armatures was a source of continued trouble, and was a very expensive operation, nor was such winding ever perfectly satisfactory. Machinery will introduce greater regularity. Of course, all armatures cannot be wound by a machine, but those of Kapp, Mather Platt, Crompton, and similar machines can be so wound. The drum upon which it is desired to wind the wire is placed between the centres of the machine, as in a lathe, and driven at the proper speed for winding. There is an instantaneous stop motion by treadle, by which the attendant can stop the machine when required. On the bed is a travelling carriage with an adjustable tension wire feed, the wire being fed from the coil behind the machine. The feed is geared up for the necessary thickness of wire,

NEW MACHINE FOR WINDING DYNAMOS.

frequently done, and no scientific result is obtained. The proper way to test is with a voltmeter as before described."

There are many things that might be criticised in the book, but we think the practical statements far outweigh what we should object to. Still, it would be sufficient to say that the best grease for lubrication, according to the author's experience, was that supplied by Elwell Parker, without particularising that its worth would go as far £5 of oil, and, in fact, to speak in many places more generally, because no individual now can have sufficient experience to warrant him placarding the best of everything.

One of the most interesting chapters in the book is the last, wherein the author details the history, development, and cost of the installation at Broomhill.

MACHINE FOR WINDING DYNAMOS.

The machine or lathe herewith illustrated has been designed by the makers for a definite object—the winding of dynamos. The development of any new industry, and especially an industry that is more or less a branch of

and the wire is wound on evenly and at the proper regular tension, the feed being reversed by hand until the proper amount is wound on. It is calculated that with the aid of this machine one man can do more and better work than two men working in the ordinary way. The machine we illustrate is made by Messrs. Wilkinson and Lister.

Results of Tenders. A gradually increasing number of local authorities are using electrical apparatus in some shape or other. Many are connecting the members of the fire brigade telephonically, or by means of bells, and no doubt a large business may be done in this direction when electricians become alive to the fact that the field awaits their advent. Aldershot has recently invited tenders for connecting the members of the fire brigade by means of electric bells. The following are the firms that tendered, and the respective amounts of each tender.—Mr. Tily, Farnham, £38 18s. 9d.; Messrs. Dale, London, £78; Messrs. Franklin, Reading, £11 19s. 6d.; and Messrs. Steven and Johnson, Aldershot, £15.

THE ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom...	3s. 3d.	6s. 6d.	13s. 6d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places...	4s. 10d.	9s. 8d.	18s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S. Next week we shall give that of SIR HUMPHREY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

THE BATTLE OF THE GIANTS.

Transformers or accumulators, that is the question; and whether it is better in all respects to use the one or the other has not yet been decided. The siege of Troy was a lengthy combat—filled with some stirring episodes; but there sword and spear formed the conquering weapons, and the deeds of the heroes have been sung to every successive generation. The contest between transformers and accumulators is of another kind. The arena may witness a victory as far-reaching as that of the Greeks over the Trojans, and of greater benefit to the world at large; but there will be no Homer to sing paeans to the victors. The struggle is not likely to be over for years, nor can the ever-increasing skirmishes of the present have much effect upon the ultimate results. Pocket-pistols and huge and massive manuscripts may turn the scale of debate in the theatre of the Institution, but the real decisive blow will come from a future giant—the Giant Experience.

The transformer troops, under the able leadership of Mr. Kapp, entered recently into the war, with banners flying and trumpets sounding, to encounter a steady and determined resistance all along the line, and it can hardly be said that ground was gained on either side. The defenders, however, of that attack have taken courage because of the unsatisfactory result of this preliminary skirmish, and, under the ægis of Mr. Crompton, have charged with might and main. Writing early, yet after the reveille has sounded and the troops have armed for the battle, but before the actual meeting of the contending parties, we cannot detail the result of the struggle, though it is almost certain we shall not be far from the mark if we venture to foretell that it will leave the contending parties pretty much as they were. The experience that has as yet been gained, either from the use of transformers or from that of accumulators, is far from being able to lead to a decisive opinion. The staunchest supporter of transformers almost always adds a saving clause to his argument in, "If accumulators can be obtained which may be depended upon for economy and lasting properties, then they will provide a better means of distribution than by transformers," but he adds in an aside: whatever may be said to the contrary "such accumulators are not in existence yet." The supporter of the accumulator agrees with his opponent *solto voce*, yet aloud disputes that his apparatus is imperfect. No one has yet formulated his requirements for a perfect accumulator, nor are we going to venture where the giants fear to tread. When one or the other of the leaders will define what is wanted or what can be given, as clearly as we can define what the industry would like to obtain in incandescent lamps—for example, thus: "a lamp with three watts per candle to give twenty candles for a thousand hours, without blackening to the

extent of losing one per cent. of the light, and costing eighteenpence"—then we can say how far the perfect accumulator will permit them to do what is required in central station lighting.

We Englishmen are apt to magnify the meaning of our words. A river here would be a brook, if not a ditch without a distinctive name, in America. Anything above a couple of score of lights is a central station here. It makes us feel large and think much of ourselves to be able to talk about so many central stations; but, after all, when we really come to look into the matter, what does it amount to? The Grosvenor Gallery installation may be approaching its 20,000 lamps, and that is the only one at present worthy of the name "central station" in the whole country. The experience of the Grosvenor Gallery has been wholly in the direction of transformers, and if we may credit unsolicited, and, so far as we can judge, unbiassed testimony, the result is not quite perfection. The experience at Kensington Court is not sufficiently large, nor is the experience at Vienna sufficiently lengthy, to warrant a decisive conclusion from the results obtained. There is a tale about a man whose mule was a little restive under chastisement, and indolent without. A castigation was necessary, and a stick was pulled from the adjacent hedge. It broke at the first stroke; another, stouter, greener, and tougher, was obtained, and for thirteen consecutive whacks appeared uninjured, yet on the fourteenth it also broke to pieces, and the mule was still indolent. *Æsop* always wrote a moral to his fables for fear the Greeks should not see it; and, following so admirable an example, we say accumulators may look well for one or two months or years, but may go to pieces the third month or year. Has experience shown that you may rely upon a depreciation of 10 per cent. being within the mark? What is the depreciation to be allowed that will give satisfaction all round?

If we have said too much about accumulators, and too little about transformers, as it is necessary to bestow an equal share of favours, attention may be directed once more to the great and almost constant loss that arises from working machinery far below its normal output. This result must, we fear, happen when transformers are used. A house wired for fifty or a hundred lamps will, as a rule, not turn on more than a fifth of the number, yet its transformer must be designed to supply current to the maximum number. What about efficiency under these circumstances? Extended experience alone will give us the facts and figures required, while the facts derived from a limited experience may become of the nature of fictions under the clearer light of time. In the workshop and the laboratory, our tests are made under the most favourable conditions, and of course efficiencies are satisfactory. The present transformer and the present accumulator

are progressive steps in the evolution of the electric lighting industry, and will play their part just as the Alliance machine played its part, and will give place to something more perfect and more efficient. Still, what we have will enable us to do what could not be so satisfactorily done three years ago; and taking into consideration the circumstances of each special case, the engineer will determine which is the better for that particular installation—transformer or accumulator. This discussion is one that more particularly interests the industry, and not the public. We know that an installation can be carried out with either; and the public will not be deterred from purchasing because one firm advocates transformers and another accumulators, any more than they are deterred from purchasing steam engines because one maker advocates stationary and another semi-portable engines. Nor has efficiency much to do with the public, when all the contention is about '001 or '002 per cent. of the original energy when normal conditions operate. Go on, then, thrashing out these points of detail, tabulating experience, fighting for opinions as held now, but leave a loophole for change due to the further experience that is to come.

ELECTRICAL TRAMWAYS.

The paper of Dr. E. Hopkinson on the Bessbrook and Newry Tramway, read before the Institution of Civil Engineers, with the discussion thereon, forms the completest survey of electrical traction as applied to tramways that exists. The importance of the subject is so great, that, feeling that all information upon it should be disseminated as widely as possible, we have obtained permission to reprint from the Institution's proceedings this paper and the discussion, for the benefit of those of our readers who may not be members of the Institution or see the Proceedings. It will be seen that "the conductor is of channel steel, laid midway between the rails." In considering the applicability of electricity for haulage purposes, we have to consider the special conditions holding in each case. In America, many conductors are overhead. At Blackpool, Mr. Holroyd Smith uses the central channel—a system which in a modified form is adopted at Bessbrook. In many cases neither of these systems is permissible, and only if accumulators can be economically applied will electricity be used. Overhead wires cannot be allowed in large towns, and local authorities absolutely refuse permission to lay a central channel, so that the field of operations is considerably narrowed. As we say, a vast amount of information relating to all these systems will be found in the paper and discussion. In many places in America, and in sparsely populated districts, or for feeding lines to main lines of railway, overhead contact is permissible.

PATERSON AND COOPER'S FITTINGS.

We illustrate this week some new fittings designed by Messrs. Paterson and Cooper for installation work. Figs. 1 and 2 represent, to a scale of half size, neat forms of switches for single lamps or for groups of from two to eight lamps. Fig. 1 is mounted on a slate or serpentine base, with polished brass or bronze dome, the knob for turning

FIG. 1.

FIG. 2.

off and on being of ebonite. Fig. 2 is mounted on a porcelain base, and has a grooved brass cover secured to the base by a bayonet joint. Both forms have throw-off springs concealed inside the switch. Larger sizes are made in similar patterns to carry current for 16 lamps.

FIG. 3.

Fig. 3 represents double pole main switches made in sizes to carry from 25 to 500 amperes. The pole blocks are mounted on a slate base, having a teak fillet round it, the throw-off springs being concealed under the base. The contact blocks, of which there are two, are carried by the brass cross piece, and kept up to the pole blocks by a strong helical spring, as shown.

FIG. 4.

Fig. 4 shows a magnetic cut-out designed for use with accumulators, the action of which is simplicity itself. It is placed in the charging circuit, and its working depends on an electro-magnet excited by the charging current. This is mounted on a slate back, its armature being attached to one end of a bell crank lever. To the other end of the lever is fastened a bridge piece, the two ends of which dip into mercury cups formed in a boxwood block. The connections are from the right-hand ter-

minial to the right-hand cup, from the left-hand cup to right-hand end of magnet coil, and from the left-hand end of magnet coil to left hand terminal. The circuit is therefore completed through the bridge piece, the ends of which dip into the mercury cups. When the charging current gets too low, the armature, from the weakening of the electro-magnet, falls, lifting the bridge piece and thus preventing a reversal of the current. By a milled nut the cut-out can be adjusted to break the circuit at any particular current within fairly wide limits.

AN ELECTRIC FIRE ALARM.

The accompanying illustrations show a new device for the indication of fire by means of an electric alarm. An examination of the figures will show that the contact is made by the expansion of a membrane. Fig. 1 shows

FIG. 1.

the membrane not in contact with the central screw. Fig. 2 shows that under the increased temperature expansion has taken place, and contact has been made with the said screw. This completes an electric circuit, and an alarm is set in motion at any point it may be found desirable. The arrangement is certainly ingenious, and it seems that the only difficulty is that there may be a sufficient rise of temperature from ordinary causes to set the alarm going without any danger of fire; but this, perhaps, might be an advantage, as many would suggest, prevention is better

FIG. 2.

than cure. On the other hand, unless the alarm was suitably placed, it might happen that the fire would get well hole without raising the temperature near the alarm sufficiently high to bring it into action.

E. RAUB'S NEW THERMO BATTERY.*

BY G. BETZ, BERLIN.

For many years it has been the endeavour of electricians to devise an electric generator which, by its construction combination, should not only surpass those in use by its simplicity, but also at the same time render possible the transformation in the most simple manner of a given amount of heat into electrical energy—in short, that the whole requirements both of manufacturers and of private persons in this respect might be completely satisfied. There is no doubt that the direct transformation of heat into electricity may give us in the near future the possibility of the production of electrical energy in the simplest, cheapest, and most practical method; therefore it would be both desirable and of great material profit if an equal importance were laid upon the improvement of thermo batteries, as lately has been given to dynamos.

A decided advance has lately been made in this province by the novel construction of a thermo battery by E. Raub, of Berlin. It is of considerable importance, because in it

* Abstract of paper in *Centralblatt für Elektrotechnik*, No. 7, 1888.

all the defects pertaining to the old thermopile are overcome, and also because both the smallness of the cost of maintenance renders it applicable for many technical purposes, especially electro plating, and the comparative ease of manufacture enables it to be produced at a very small first cost.

As is seen in the accompanying figure, the battery consists of two principal parts—1, the ring-shaped elements, and through them the corresponding heat channel; 2, the cooling arrangement, which, insulated, surrounds it. The corona standing behind the tripod in the figure, shows a single element; the positive electrode, formed of a metal alloy, is cast in the form of a ring round a copper "heat ring." By this means a particularly strong and intimate connection is formed. The "cold ring" surrounds this, outside a second copper ring with radiating cooling lobes. The negative metal, which is hard soldered with sheet tin to the heat ring in such a manner that local currents at the points of contact are entirely avoided, is soldered, after the elements are laid one

upon the other, to the cooling lobes of the next element. A number of similar thermo-elements of any desired dimension are fastened together between two cast-iron plates by means of four iron rods with screws and nuts, and well insulated from each other with fire proof material, the single-element rings stand centrally over each other, forming a strong and secure hollow cylinder, which serves as a heat chamber. The heat can be obtained from any suitable source. For the smaller apparatus, such as is shown in the figure, a ring shaped Bunsen gas burner is sufficient. For larger sizes, a coal or coke fire is required. The burner is screwed to the lower end of the built-up heat channel, and the flame impinges upon the heat rings of all the elements at the moment it unites with the oxygen. The heat is distributed equally on all the elements by means of a slender pipe fastened to the top of the heat chamber and projecting inwards, which goes through into an angle pipe to a wide stove pipe, this is closed at the bottom, screwed to the tripod, and communicates with a chimney having a good draught. The heat ascending in the chimney draws up fresh air, not only through the lower part of the mouth of the heat channel, but also through air tubes brought into

the principal pipe, well insulated outside, and pressing against the elements, so that the outer contact points of the ring elements are kept cool by the air draught. A damper for regulation of the draught is advisable.

The use of ring-shaped elements in connection with this forced air draught permitting the greatest possible development of heat, as well as the production of the greatest possible difference of temperature, produces a very economical arrangement; in it is combined a battery quickly and easily set in action, taking up a very small amount of room, at the same time susceptible of being heated with ordinary gas, and easily mounted on a stand. The durability and strength of the elements is a great advantage, together with the ease with which damaged rings can be taken out, either for repair, or for insertion of new ones, which are to be obtained singly from the makers.

For electro-deposition of metals, electrolysis, &c., the three smaller sizes, gas-heated, are most applicable; these consume 300, 500, and 900 litres of gas per hour, giving a current of 10, 20, and 40 amperes, with an E.M.F. of 3 volts. With a consumption of 1 cubic metre of gas per hour, these batteries produce a return of 80 volt-amperes, while older-known constructions give at most 27 volt-amperes.

CHELSEA.

The report of the surveyor to the vestry, Mr Geo. R. Strachan, on the lighting of the Town Hall buildings with electric light, shows that ten electric lighting companies were asked to give estimates of the cost for providing plant, &c., for doing the work. For the guidance of the contractors the following standard of light was given:—

Town Hall	320 candle-power
Council Chambers	350 "

The light in the platform ante-room, the tea-room, the lower hall, and the main corridors was to be in the same proportion as what has just been given; in all other matters the firms were allowed a free hand. The whole of the firms invited sent in tenders; eight of them proposed a separate installation, while two, in connection with local companies, proposed to supply from a central station. Messrs. Drake and Gorham included in their tender a duplicate set of engines and dynamos; the other firms included accumulators in their estimates, or expressed the opinion that they should be provided. Messrs. Crompton and Co. estimated for providing new electroliers and fittings throughout, but the others estimated for combining the electric light fittings with the present gas fittings. The local companies proposed to have an accumulator, and supply the current by a motor. The prices for which a separate installation was offered vary from £1,935 to £800, but, as Mr. Strachan so ably points out, these figures form no guide whatever to the determination as to which tender is the most desirable. The study of them resolves themselves into a question of what is not included in the sum. Some include accumulators, some fittings and electroliers, some exclude wiring, building, and contractors' work, foundations for engines, &c., and having these things in mind, Mr. Strachan reduces the tenders as far as possible to a standard.

The firms each supplied an estimate of the annual cost per year for the maintenance of a thousand hours a year, and the estimates vary from £558 to £246. The estimates for this cost of maintenance are not comparable. Thus, one firm includes £182 a year for labour, &c.; another does not include this item, but calls attention to the necessary addition to the estimate. One firm puts the lamps renewal at £90, another at £10. One firm estimates the life of the lamp at 2,000 hours; another at 1,000 hours. One firm puts coal at 20s. per ton; another at 16s. per ton. One firm allows £150 for depreciation, while another allows £36. As Mr. Strachan says, "It is impossible to reconcile these differences—they are as amusing as they are perplexing," and he therefore made no attempt at standardising. These calculations show, taking all things into consideration, the total cost of gas to be 19d. per 16 candle power per hour; the cost for comparison with the electric light is taken at 15d. per 16-candle power per hour.

The following is a table of the annual cost of the systems tendered for when the estimates have been standardised by Mr. Strachan as well as able:—

	Annual cost	Cost of 16 c.p. per hour.
Chelsea Electricity Supply Co.	£583 7 0	467
Cardigan Electric Light Co.	536 8 4	429
Drake and Gorham	516 5 6	413
Siemens Brothers and Co.	502 7 0	402
Edison, Swan and Co.	483 11 0	395
Crompton and Co.	462 4 0	369
Mr. Ronald Scott.	453 15 0	363
Smith and Co.	450 13 0	361
The Anglo American Brush Co.	444 5 0	355
Holmes and Co.	440 14 0	355

It may be taken that the cost by a separate installation will be from 2½ times to 2¾ times the cost of gas, and the cost from a central station will be three times that of gas.

The following were the estimates sent in by the selected firms:—

CHelsea ELECTRIC COMPANY.

This company proposes to supply the current from a central station, and to charge for the electricity by meter. Their estimate for providing conductors, wires, castings, switches, cut-outs, 8 circuits, 291 16 c. p. incandescent lamps, and plain electric fittings, is £507 10s. They propose to supply the current at 8d. per Board of Trade unit, which is between ½d. to ¾d. per 16 c.p. per hour. The company has not a central station yet. They estimate the annual cost, allowing 1,000 hours for the life of the lamps, at £543 4s. This estimate standardised is:—

Lamps and current	£543 4 0
Interest on £507 at 4%	20 3 0
Depreciation on fittings	20 0 0

or 467d. per 16 c.p. per hour.

CARDIGAN ELECTRIC COMPANY.

This company proposes to supply the current from a central station, and to charge for the electricity by meter. Their estimate for providing conductors, wires, switches, cut-outs, 235 16 candle-power lamps, adapting the gasoliers to the electric fittings, &c., is £566 19s. They would provide and keep in order at their own cost an accumulator to hold current for six or seven hours. The charge for the current will not exceed 7d. per Board of Trade unit, which they say is as near as possible ½d. per 16 candle-power per hour. According to the usual means of calculating the cost, the price would have to be less than 7d. per unit to reduce the cost to ½d. of a penny per 16 candle-power lamp per hour. The annual cost would be:—

300 lamps for 1,000 hours each, at ½d. per lamp per hour	£426 13 4
Depreciation	20 0 0
Interest at 4% on	£566 19 0
Add to make up to 300 lamps	83 1 0

Lamp renewals	£650 0 0
	26 0 0
	63 15 0

or 429d. per 16 c.p. per hour.

DRAKE AND GORHAM

This firm proposes to provide a duplicate plant without accumulators. Their estimate for two 12 horse-power Marshall engines with boilers, two Worthington pumps, two Elwell Parker dynamos, two driving belts, 306 16 candle-power lamps, switchboards, switches, cut-outs, wires, &c., is £1,935 9s. The estimate does not include builders' work, structural alterations, or ornamental fittings. Their estimate of the annual cost is:—

Coal, 86 tons at 16s.	£68 16 0
Water, oil, waste, &c.	19 0 0
Depreciation	75 0 0
Lamps, life 1,500 hours	40 0 0
Interest 4% on £2,000	80 0 0
Labour, £2 per week	104 0 0

The estimate standardised is:—

Coal, 86 tons at 20s.	£86 0 0
Oil	20 0 0
Labour	78 0 0
Lamp renewals	63 15 0
Depreciation on	£1,935
Add for omitted works	400

Interest on ditto at 4%	£2,335 at 7½% 175 2 6
	93 8 0

or 413d. per 16 c.p. per hour.

Co.

Their

lators, builders' work, an engine-house, &c., in the estimate of the annual cost is:—

Coal, 60 tons at 20s.	£60 0 0
Oil, waste, &c.	12 0 0
Interest, 4%	65 12 0
Depreciation, 10% on £800	80 0 0
Do. 5% on £750	37 10 0
One set of lamps, £90	90 0 0
Repairs, 2½% on £800	20 0 0

Their estimate standardised is:—

Coal, 60 tons at 20s.	£60 0 0
Oil	20 0 0
Labour	78 0 0
Lamp renewals	63 15 0
Depreciation on	£1,640
Add for omitted works, &c.	800

£2,440 at 7½%	183 0 0
Interest on do. at 4%	97 12 0

£502 7 0

or 402d. per 16 c. p. per hour.

EDISON AND SWAN COMPANY.

This company proposes to generate the current by gas power. Their estimate for a 14 h. p. "Otto" gas engine, a 220 light Edison Hopkinson dynamo, an accumulator, 263 16 c. p. lamps, wires, switches, cut-outs, &c., is £1,220. It does not include fixtures, structural alterations, gas or water supply. Their estimate of the annual cost is:—

Attendance	£78 0 0
Gas, at 2s. 10d. per 1,000 feet	144 8 0
Oil, waste, &c.	44 0 0
Lamp renewals	42 10 0
Upkeep of accumulators	41 10 0
Upkeep of engine, &c.	18 0 0
Interest, 4% on £1,220	48 16 0

£417 4 0

This estimate standardised is:—

Gas, at 2s. 5d. per 1,000 feet	£124 0 0
Oil, &c.	20 0 0
Labour	78 0 0
Lamp renewals	63 15 0
Depreciation on	£1,220
Add for omitted works, &c.	500

£1,720 at 7½%	129 0 0
Interest on do. at 4%	58 15 0

£483 11 0

or 395d. per 16 c.p. per hour

CROMPTON AND CO.

This firm proposes to generate its current by steam power. Their estimate for a multitubular boiler, Willan's engine, Crompton dynamo 260 16 c.p. lamps, cut-outs, wires, switches, indicator, new fittings, &c., is £1,541. 17s. 6d. It does not include an accumulator. Their estimate of the annual cost is:—

Coal, 50 tons at 17s. 6d.	£43 15 0
Lamp renewals (life 2,000 hours)	32 10 0
Oil, waste, &c.	20 0 0
Labour (half time man and boy)	58 10 0
Depreciation, 7½% on £1,180	88 10 0
Interest at 4% on £1,541	61 13 0

£304 18 6

This estimate standardised is:—

Coal, 50 tons at 20s.	£50 0 0
Oil, waste, &c.	20 0 0
Labour	78 0 0
Lamp renewals	63 15 0
Depreciation on	£1,541
Add for omitted works, &c.	637

£2,178 at 7½%	163 7 0
Interest on do. at 4%	87 2 0

£462 4 0

or 369d. per 16 c.p. per hour.

THE BRUSH CO.

This firm proposes to use steam power. Their estimate for a 22 h.p. boiler, brush engine, dynamo 266 17 c. p. lamps, cut-out, meter, switch-boards, switches, belt, &c., is £800. It does not include wiring, fittings, builders' work, or accumulators. Their estimate of the annual cost is:—

Coal, 64 tons at 20s.	£64 0 0
Water, oil, &c.	15 16 0
Lamp renewals (life, 1,000 hours)	50 16 0
Labour	78 0 0
Interest 4% on £800	32 0 0

This estimate standardised is:—

Coal	£64	0	0
Oil, waste, &c.	20	0	0
Labour	78	0	0
Lamp renewals	63	15	0
Depreciation on	£800		
Add for omitted works, &c.	1,100		

Interest on do. 4% £1,900 at 7½% 143 10 0

or 365d. per 16c. p. per hour

GREEN SMITH AND CO.

This firm proposes to use gas power for their estimate. Their estimate for a gas engine, two dynamos, storage batteries, 247 16 c. p. lamps, wires, fittings, &c., complete, is £1,330. It does not include laying gas on to the engine. They call attention to the fact that an attendant will be required. Their estimate of the annual cost is:

Lamp renewals	£50	0	0
Oil, waste, &c.	8	0	0
Depreciation	54	0	0
Gas	80	0	0
Interest	54	0	0

£246 0 0

This estimate standardised is:—

Gas	£110	0	0
Oil, waste, &c.	20	0	0
Labour	78	0	0
Lamp renewals	63	15	0

Interest on 4% £1,930 at 7½% 144 15 0

or 353d. per 16c. p. per hour.

ELECTRICAL TRAMWAYS: THE BESSBROOK AND NEWRY TRAMWAY.*

BY EDWARD HOPKINSON, M.A., D.S.C., ASSOC. M. INST. C.E.

Although the subject of the application of electricity to locomotion has been much discussed during the last few years, comparatively few attempts have been made at its practical realisation. The first electrical tramway in the United Kingdom, constructed between Portrush and Bushmills, in the north of Ireland, was opened for traffic in October, 1883, and has since been extended. In his lecture before the Institution in March, 1883, the late Sir William Siemens gave a general description of this line, and the electrical details were further discussed in a paper read before the Society of Arts in April, 1883, by the author. In 1883 Mr. Magnus Volk constructed a line along the foreshore at Brighton, upon which a single car has since been running regularly, and Messrs. Siemens Bros. have a short length of line in operation on the pier at Ryde. On a larger scale is the tramway along the promenade at Blackpool, two miles in length, constructed by Mr. Holroyd Smith. The construction and method of working have been fully described by Mr. Smith, in a paper read before the British Association at the Birmingham meeting, 1886. The conductor, as in the before mentioned lines, is continuous, and several cars are in motion on the track at the same time. The cars are of various sizes, and accommodate from thirty to fifty six persons. The track is nearly level, and a speed of six miles per hour is generally attained. Mr. Reckenzaun and Mr. Elieson have also done much in the application of storage batteries to tramway work.

In none of these instances has any attempt been made at the regular haulage of minerals and goods, nor at the operation of cars larger than the ordinary tramway type. Probably in no case has the effective power of any single motor exceeded about 4 horse power. In July, 1881, Mr. Barcroft, of the Bessbrook Spinning Company, whose extensive flax mills and stone quarries are situated at Bessbrook, about three miles from Newry on Carlingford Lough, suggested to the author that the line, which the company had decided to make between Newry and Bessbrook, for the carriage of coal and flax from the wharves to the mills and the down traffic of manufactured goods, might be worked electrically, for which the abundant water-power available offered exceptional advantages. The following conditions were to be met. Ten trains to be run in each direction per day, providing for a daily traffic each way of 100 tons of minerals and goods, and capable of dealing with 200 tons in any single day, in addition to the passenger traffic; the electrical locomotive to be capable of drawing a gross load of eighteen tons on the up-journey, in addition to the tare of the car itself and its full complement of passengers, at an average speed of six miles per hour, and a load of twelve tons, at an average speed of nine miles per hour. The company agreed to place the line entirely at the disposal of the author for a period of time, and to purchase the electrical plant at a fixed sum, when the above conditions had been complied with, and it had been shown that the cost of working, as evidenced by six months' trial, did not exceed the cost of steam traction on a similar line. The work was commenced in November, 1884, and the line opened for traffic in October, 1885, and was formally taken over by the company as having fulfilled the conditions of the contract in the following April. Since that time it has been in regular daily operation.

GENERAL DESCRIPTION OF THE LINE.

The line commences at the Edward-street terminus of the Newry branch of the Great Northern Railway, and runs parallel to it for about ½ mile; and then, passing through a cutting, follows the course of the Camlough stream, running under the central arch of the viaduct on the main Great Northern line, which crosses the valley at

* Paper read before the Institute of Civil Engineers, and reprinted by permission from the *Transactions* of the Institute.

§ See *The Electrician*, September 10, 1886.

a height, in the centre, of 126ft. Near the viaduct is the first station, close to the small village of Craigmere, and an outlying mill of the Bessbrook Company. Proceeding up the valley, with a gradient of 1 in 50, the county road is crossed, diagonally, by a level crossing, 50 yards in length, near which is the second station, Millvale, at which point

PLAN OF ARRANGEMENT OF LINES AT BESSBROOK.

Scale 1 inch = 100 feet.

FIG. 1.

the line crosses the stream, and the turbine and generating dynamos are erected. The line again crosses the stream $\frac{1}{2}$ mile from Millvale, and thence runs into the terminus at Bessbrook, where a station and carriage shed are erected. The total length of the line is 3 miles 2.4 chains; and the average gradient 1 in 86, the maximum gradient being 1 in 50 (Fig. 1). The gauge is 3ft. and the rails are at present single, but land has been acquired for a double line. At each terminus is a loop of 55ft. radius (Figs. 2 and 3), so that the cars do not need reversing, except in coupling

FIG. 2.

up the waggons or shunting in the sidings. The permanent way has been laid out and constructed under the supervision of Mr. J. L. D. Meares.

LOCOMOTIVE EQUIPMENT.

The locomotive equipment of the line consists of two passenger cars, 33ft. and 21ft. 8in. long respectively, each provided with a motor. The body of the car is carried on two four-wheeled bogies with a wheel-base 4ft. 6in., the motor being carried on the front bogie independent of the body of the car (Fig. 4). This arrangement

PLAN OF ARRANGEMENT OF LINES AT NEWRY.

Scale 1 inch = 100 feet.

FIG. 3.

enables the cars to traverse the 55ft. curves at the termini with great facility, and also relieves the body of the car from the vibration due to the driving. The body of the longer car is divided into three compartments: the front one covers the motor; the second forms a second class compartment, seating twenty-four passengers; and the

third, a first-class compartment seating ten passengers, separated from the second by a cross-passage. The front bogie carrying the motor has an extended platform, projecting 3ft. 7in. beyond the body of the car, and communicating by a slide-door with the dynamo compartment, thus giving the driver direct access to all parts of the driving machinery, which are at the same time entirely boxed off from the passenger compartments. All four wheels are braked by a powerful screw-brake worked from the front of the driving platform, on which is also fixed the switch-board controlling the motor. The wheels of the back bogie are braked by a chain brake worked from the cross passage, and are under the control of the conductor. This brake is also prepared for coupling to the waggons. The total weight of the car is 8½ tons, distributed as follows:

	Tons, cwt., qrs.
Car body	3 6 1
Loading bogie	1 17 2
Trailing	1 0 0
Dynamo, bed-plate, armature and accessories	2 1 1
	8 5 0

The shorter locomotive car is similar, but without the first-class compartment. Both cars were built by the Ashbury Carriage Company, of Manchester. There is also a third passenger-car of the same length as the first, and accommodating 41 passengers, and similarly carried on two four-wheeled bogies. This car weighs 5½ tons, and was constructed by the Starbuck Company, of Birkenhead.

THE USE OF WAGGONS WITH FLANGELESS WHEELS.*

Apart from the electrical working of the line, an important and novel feature is the plan by which the waggons used on the line can also be used on the ordinary public roads, so avoiding the necessity of transshipment, and enabling goods to be loaded at the wharves and drawn to the line by horse-power, and again delivered at any part of the mill premises. The plan was originally suggested in 1880 by Mr. Alfred Holt, M.I.C.E., of Liverpool, and was embodied in the Lancashire Plateways Scheme, for which a Bill was lodged in the autumn of 1882, and subsequently withdrawn. The idea has been worked out in a practical form with great success by Mr. Henry Barcroft, of Newry, one of the directors of the company. The wheels of the waggons are constructed without flanges, with tires 2½in. wide, which is sufficient for use on ordinary roads (Fig. 5). Outside the tramway rails, which are of steel, and 41.25lb. per yard section, second rails are laid, having a section of 23.75lb. per yard, with the head ½in. below the head of the larger rails. The flangeless wheels run upon these lower rails, the ordinary rails forming the inside guard (Fig. 6). The wheels are loose on the axles, but the latter are not fixed, but are carried in journals, so that there is freedom in both wheel and axle, which considerably reduces the friction, especially in travelling round curves. The front part of the waggon is supported on a fore-carriage, which can either be pinned or allowed freedom of motion, as in an ordinary road vehicle (Fig. 4). The buffers are fixed on the truck-frame, and no buffing is done against the fore carriage. There is a single central coupling arranged to engage in a jaw in the fore carriage, so as to guide it when not pinned. Shafts are attached to the fore-carriage when the waggon is to be used on the ordinary roads. The weight of each waggon without the shafts is 23½ cwt., and the waggons are of sufficient strength to carry a load of two tons. This load is not too much for a single horse on roadways where there are no steep gradients; on steep gradients two horses are required. The double line of rails is not continued round the curves at the termini, but a take-off is arranged (Figs. 2 and 3), into which the waggons are run by the car. The shafts are then affixed, and the waggons drawn off by horses. Twenty-two of these waggons have been supplied to the Tramway Company by the Ashbury Carriage Company, and have been in constant use for eighteen months. Experience has shown that the wear and tear, both on the wheels and rails, is not excessive, and that the traction does not much exceed, if at all, that of ordinary trucks with

* Illustrations of these Waggons (Figs. 4 and 5) will be given with the continuation of the article.

hanged wheels. No difficulty has been found with the horse traction on ordinary roads, and the taking on and off is conducted with great rapidity. The utility and wide applicability of this plan are obvious, and it may do much to develop the introduction of short tramways where the cost of transhipment would be fatal to the ordinary methods of working.

HYDRAULIC AUTOMATIC GATE-OPENER.

Another novel device introduced by Mr. Barcroft is an automatic hydraulic apparatus for opening the gates protecting the level crossing of the county road. The regulations of the Board of Trade require that gates should be provided at such crossings, and that they should be closed immediately after the passage of the train. To avoid the cost of a gateman, the following plan has been adopted. As the locomotive car approaches the crossing at a distance of about 50 yards, a suitable arm attached to the foot-board strikes a lever pivoted on one side of the permanent way, and turns it over. The lever is connected with a three-way cock, which, when opened, withdraws the water from a cylinder provided with a float. To this float a wire rope is attached, which opens the gates on both sides of the crossing as the float sinks in the cylinder. After

limits, couples one of a pair of right and left-hand bevel wheels driven by a wheel on the governor spindle to a small countershaft, geared with the valve spindle.

(To be continued.)

THE ELECTRICAL TRANSMISSION OF ENERGY FOR THE FEEDING OF CANALS.*

The novel application of the electrical transmission of energy for the supply of water to canals having reaches at different levels, and especially lock canals, has recently been designed by M. Edmond Henry, a former pupil of the *Ecole Polytechnique*.

Of the different varieties of canal, those known as canals with dividing ridge (*a pond de partage*) offer the greatest difficulties of feeding. The upper reach in the vicinity of the summit line receives from water courses a minimum supply for this reason, in the greater number of existing canals the height of the summit level pond has been made dependent upon the feeding with detriment to economy. In certain cases use is made of natural ponds, or separate reservoirs and feeders are constructed for the supply of the

passing the crossing, the car strikes a second lever similarly situated, and connected by a second wire rope to the three-way cock. When the lever is thrown over, the cock is turned so as to admit water from a cistern placed at a higher level into the cylinder, raising the float and closing the gates, the float being assisted by a balance weight attached to each gate.

GENERATOR STATION.

The generating machinery is fixed at Millvale, a distance of 58 chains from the Bessbrook terminus. At this point, in close proximity to the line, there is an available fall of 14ft. in the Camlough stream, down which there is a guaranteed minimum flow of 3,000,000 gallons per day. The turbine is an inward flow vortex wheel with double buckets, working on a horizontal shaft extended into the flymo shed, from which the dynamos are driven direct with belts. The capacity of the wheel is 1,504 cubic feet per minute, and when running at 290 revolutions per minute should develop a maximum power of 62 h.p. It is worked with a tail draught of 13ft. The admission of water is controlled by a shutter-valve regulating the flow uniformly through each bucket of the wheel, and actuated either by hand or by a centrifugal governor. The latter is not direct acting, but as its balls rise or fall beyond certain

summit-level pond, independently of the intermediate reaches.

Canals which are fed by means of steam or hydraulic machines, such as that from the Aisne to the Marne, and that from the Marne to the Rhine, are those which lend themselves most readily to the application of the electrical transmission of energy, combined with the use of natural hydraulic power. In most canal schemes the latter may be found without much difficulty, but its employment may be difficult or of little advantage if the difference of altitude of the motors and of the upper reaches, and the distances to be traversed, are considerable. If pumps worked by turbines are utilised for the object in view, a very costly conduit, involving great resistance, is requisite for forcing the water to the upper reach of the canal; moreover, this water must be taken by the pumps at the level and in the vicinity of the motors, and then raised through the whole difference of level to the summit-level pond.

In the electrical system proposed by M. E. Henry, instead of having to force the water from the hydraulic machine works, by means of a costly canalisation, to the inlet of the summit level pond, it is possible to bring the water through feeders to an intermediate reach which can be naturally

* Translated from the *Revue Industrielle*.

supplied, and from this to raise it to the successive levels, and ultimately to the upper reach. This arrangement dispenses with all canalisation; the pump-shafts will thus have at each point only the length corresponding to a lock, and loss by leakage will no longer have any importance.

The canalisation is here replaced by conducting wires carried on posts like telegraph lines. In this way the expense and the time requisite to establish an installation are considerably reduced.

The installation is thus composed of hydraulic machine works, in which are driven the transmitting dynamos; the wires connected to which transmit to a distance the energy for working other similar dynamos the motors. The latter are directly connected with various sets of pumps, either rotary or with piston, which have only to raise the water through the height of a lock, taking it from the end of one reach to the adjacent extremity of the next in altitude. Under certain circumstances, the electrical power could be employed for the lighting of the canal, for transmission of power to a given point, or for haulage purposes.

One of the main advantages of the use of electricity in conjunction with a system of force-pumps consists in the fact that the loss of energy in the conducting wires, and, consequently, the efficiency, does not vary for a given distance of transmission, whether this distance be in a horizontal or a vertical direction.

With a view of showing the indubitable advantage of the use of electrical power, the inventor establishes a compar-

III., or from a reservoir obtained in the valley of river I. by the construction of a slight dam. The rivers II. and III. supply to low-water mark 2.5 metres per second, which can be brought to the summit-level pond. River I. has a rate of discharge to low water mark of 26.5 metres per second, and will give, without very great expenditure in works, a fall of 22 metres, which, utilised in hydraulic machines—turbines with horizontal axis, Girard system—represents theoretically 7,773 h.p. Only 19.23 metres of the discharge are taken; so as to obtain a motive power of 5,640 horses. The remaining 7.27 metres are conducted directly to the reach on the incline 40.

This charge of 22 metres can be obtained by constructing a slight dam in the valley of river I., which will produce an accumulation in the direction of 44, whence the waters can be conveyed to the point marked on the plan where the hydraulic motors are installed.

Feeding of the Different Reaches.—The power developed by these motors may be utilised in various ways for conveying water to the various reaches of the northern side as well as to the summit-level pond; for those on the northern side are fed by means of the latter. The various reaches of the north side, in the scheme considered, have their water levels respectively at 8, 16, 25, 32, 40, 49, 50, and 59. Consequently, if the trench from the valley were so constructed that, when continued to the commencement of the reach at 40, its water level should be 41, the feeding could be effected directly without the use of elevating

ison between the two methods of installation, utilising the same quantity of energy. The comparison to be made is between the volumes of water which can be raised by each system to the summit-level pond. Taking into account, however, the somewhat low efficiency in the electrical transmission of power to a distance, it should be observed that this latter means does not allow of the water being raised to as great a height as with the system of pumps and conduits, and, therefore, the comparison should be made in each particular case by taking into account the distance of transport and the height through which the water has to be raised. In the example given below, which is cited by M. Henry, it will be seen that the efficiency by volume may be more advantageous in the case of electricity. The data of the application are analogous to those which would occur in practice.

We will suppose that a canal is to be established according to the section and plan shown in the accompanying sketch, and that the district is mountainous, with steep inclines in the valleys. It is easy to calculate the expenditure of water in working, as well as the loss by evaporation and infiltration. In the present case it is estimated that each vessel of large tonnage requires 120,000 cubic metres of water for its passage from one level to another.

A certain supply of water which can be brought to the canal is obtained either from the neighbouring rivers II. and

machinery. But the water has still to be brought to the levels 49, 50, and 59, and in quantity sufficient in the latter case to effect the feeding of the reaches on the southern side.

The figures and conclusions arrived at by M. Edmond Henry are as follows.

Feeding of the Reach at the level 59 by Hydraulic Motors and Pumps. The machines placed at the level 20 receive the water which gives the motive power (19.23 c.m. per second with a fall of 22m.) through a supply trench, having a fall of 0.10m. per kilometre, flowing into an iron tower 25m. high, sunk in the slope of the adjacent hill in the same manner as a tubular pier, from the foot of which proceeds the conduit carrying the water to the turbines. This tower, which answers the purpose both of a charging column and a reservoir, would be from 12 to 15 metres in diameter. This conduit, from the configuration of the ground, would be about 200 metres long, and would be laid either in a covered or an open way.

The machines thus receive a quantity of water representing

$$\frac{19.23 \times 22}{7.5} = 5640 \text{ h.p.}$$

The force conduit of the pumps, which has to be taken to kilometre 50.5, starting from a point opposite kilometre

puzzle even an expert watchmaker to remove. The advent of electricity in its modern and manifold branches of utility has forced upon us the importance of this question: How can we prevent this magnetism from gaining a damaging influence upon our watches? or, if not prevented, how can we best and most speedily repair the damage done?

Let us not look upon the question lightly, but rather in all earnestness. Let us bear in mind that, while the powerful dynamo in the engine-room of the manufactory, the business house, or the ocean steamship, sends forth its currents through many lines to furnish light or power, it sends forth also a very different influence, and one that makes mischief with the watch carried by the engineer or electrician, the visitor to the works, or the captain, or the pilot who may happen to approach for a moment within the influence of such a dynamo. Let us not forget that, in the latter event, serious results may follow, for, by the captain's chronometer, in conjunction with the compass, the great ship is sailed. We should bear in mind that, in the manufacture of our best watches, the object of the maker is to confine in the smallest space possible the greatest strength and durability. In order to accomplish this object he finds it necessary to use, for the principal parts of the watch, hardened steel, a material decidedly susceptible to the influences of magnetism. The hair spring and the balance wheel, vital parts of the watch, are thus frequently constructed; and even though the balance be made of a combination of metals, the steel in the little points on the wheel may be attracted to the little steel screws necessary to perfect firmness in the larger mechanism of the watch; for these screws may be readily charged with magnetism of sufficient force to be long retained and to exert a continual influence over the other magnetic matter. The escapement-wheel likewise of steel if durability be desired—becomes easily magnetised also, and its movement is seriously retarded. Then the hair spring, with its delicate coils close together, may be so polarised that the coils on the side next to the nearest steel screw will all adhere to each other, and play havoc with the motion of the watch.

Thus our very best timepieces are most susceptible to the influence which may, and often does, retard them to the extent of several hours a day.

In my work as an investigator of this subject, which has extended over a period of several months, I have formed three separate solutions of the problem: First, to have the watch made of material that cannot be magnetised; second, to enclose the works in an iron case, so as to shield the vital parts of the watch; and third, to apply efficient means to demagnetise the watch that has not been favoured with the safeguards.

With regard to the first solution, I have had occasion to experimentally test its efficiency. I have applied the most complete magnetic tests to watches made by a well known watch company, which were claimed to be perfectly free from all magnetic influences. The hair-spring and balance-wheel of these watches are made of an alloy of palladium. I have no hesitation in saying, after subjecting these watches to the strongest magnetic influence in the Westminster Electric Works, that their claim to recognition as non-magnetic timepieces is fully sustained. I have had one of these watches perfectly timed to run with another, and subjected the two to opposite extremes as regards magnetism, yet discovered no deviation in their time-keeping. The one was wholly free from the magnetic influence; the other was running at a point between the pole pieces of a most powerful magnet. I have watched both of them closely for weeks, without being able to detect any difference in their time.

Taking the hair spring and balance wheel from a watch, I have placed them upon a little cork float in the water, and then approached them with a most powerful magnet, without being able to detect the slightest motion of the little float or its burden, whereas the ordinary steel hair-spring and balance-wheel, subjected to a similar test, were so strongly attracted that they not only moved the cork float, but jumped from it to the magnet instantly.

While it is true that the screws and a large portion of the other mechanism in these watches are made of steel,

yet all the delicate movements in the works are so entirely non-magnetic that, although the steel parts should be charged with magnetism to the highest degree, there would be no perceptible effect exerted upon the running of the watch.

Concerning the second solution of the problem—that is, shielding an ordinary watch against magnetic influences by enclosing it in an iron case—I would say that I have not personally experimented with them; but acquaintances of mine, entirely competent to do so, have given me an excellent idea as to what such watches are capable of. Watches in such case have been very successful in resisting the ordinary influences of the dynamo room. But I would not advise that they be exposed to the influence of very strong fields, because, in that case, they would be magnetised and lose time.

Now for the third solution of the problem. Since it is true that comparatively few non-magnetic watches are in use, and that there are a great many of the ordinary watches with steel works, the question comes up naturally: How can we best demagnetise the watches if they have become injuriously magnetised?

An old way of doing this was in placing the magnetized timepieces in close proximity to a dynamo, then revolving the watch rapidly by means of some mechanism, and slowly removing it from the magnetic influence. This is a very unreliable cure at best, and in many instances quite ineffective. A much better method has presented itself to me. I had occasion recently, while constructing instruments for the alternating current, to observe some facts in connection with this kind of current and its peculiarities, which were suggested to me as being entirely available for use in the process of demagnetising watches. In sending an alternating current through a solenoid, without breaking the circuit in the latter, I found that the steel core had lost its magnetism entirely. Magnetising the core as strongly as I might before this operation, it would be, as I discovered, entirely demagnetised after submission to the process described. Then I found the same proposition to be equally true as applied to a whole handful of steel particles. They might adhere to each other ever so strongly before the operation; but if I endeavoured to pick one of them out of the solenoid with the circuit undisturbed, the steel particle would come out entirely alone, wholly demagnetised and free from attraction to the others. Then I tried a watch whose steel pieces were thoroughly charged with magnetism, and I found that the same process exerted the same effect upon the watch as upon the steel core or upon the many particles of adhering steel. It was utterly demagnetised in all its parts, perfectly cured of its magnetic ailment. It would be unsafe to bring such a perfectly restored watch again within the influence of magnetism unless the owner be desirous of again resorting to the still reliable process described. The solenoid need not be described to electricians. It is a very simple contrivance filled almost to the top with soft iron wire, leaving just room enough at the top, if designed for the purpose described, to allow the insertion and removal of the watch in the manner noted. Any person can apply the process successfully, and if it be in a jeweller's store, or any other place lighted by incandescent lamps supplied for alternating current, the person need only remove the lamp from its socket, insert an attachment plug in its stead, connecting the current with such a solenoid, dip the watch in the hollow end of the solenoid, and, after leaving it in there a while, remove it without disturbing the circuit. In this way a perfect cure for magnetised watches might be applied in any store, factory, or other establishment having alternating incandescent lighting plant. In conclusion, I have only to say that the first solution of the problem described above, namely, that of getting perfectly non-magnetic watches, is the best and safest one for those whose timepieces are liable to be subjected to magnetic influences. I may also add that the third method or cure described demonstrates the wonderful resources of the alternating system of electricity, which, though it may work damage like other systems, has yet within its own qualities a perfect curative power, which cannot be claimed for the continuous or direct current.

PROVISIONAL PATENTS, 1888.

MARCH 31.

4844. Improvements in or relating to holders for incandescent electric lamps, by which they are made applicable as combined holders and circuit closers and breakers. William Phillips Thompson, 6, Lord street, Liverpool. (Napoleon Eusebe Garczynski.)

4875. Improvements in machinery for raising and lowering submarine telegraph or other cables. Alexander Wilson and John Furwood Dale, 3, Elm-court, Temple, E.C.

APRIL 3.

4929. Improvements in magneto-electric generators. Webster Gault and George Haseltine, 52, Chancery-lane, London. (Complete specification.)

4940. Improvements in and relating to alternating current dynamo-electric machines. Thomas Parker, 70, Market street, Manchester.

4945. Improvements in the method of coupling together alternate current electric machines. C. Funday Proctor, 46, Lincoln's Inn Fields, London, W.C.

4961. Improvements in apparatus for the changing and regulating of electric currents. Alfred Julius Beult, 323, High Holborn, Middlesex. (Stefan Doubrava, Austria). (Complete specification.)

APRIL 4.

5023. Generation of electricity by tidal or river power. Alfred Henry Mobay and Alfred Foster Davies, 15, Great St. Helen's, London.

APRIL 5.

5069. A combined mechanical and electro-magnetic motor. Charles Adams Randall, 7, Alfred-street, Montpelier-square, West Brompton, London.

5082. Electricity meters. Robert Percy Sellen and Robert Cattley Jackson, 47, Lincoln's Inn Fields, London.

5088. Method of and apparatus for electrical signalling or announcing in connection with telephone circuits. Pierre Leon Kenchoun, 28, Southampton-buildings, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

APRIL 26, 1887.

6104. Improvements in electrical measuring instruments. Arthur Le Nive Foster and Frederick Vilhelm Andersen, 156, Strand, London, W.C.

APRIL 28, 1887.

6212. Improvements in or connected with induction apparatus and the use of it in studying dynamo electric machines. James Swinburne, Shona, Chelmsford, Essex.

MAY 17, 1887.

7184. Improvements in electric arc lamps. William Mackie, Tates Road Yard, T. small-street, Middlesex.

JUNE 1, 1887.

7350. Improvements in or connected with telephones for indicating and recording the number of times that a telephonic instrument is used for ascertaining payments due or for other purpose. David Johnstone Smith and Herbert Feshlen Jackson, 47, Lincoln's Inn Fields, London, W.C.

JUNE 7, 1887.

8159. Improvements in effecting electric telegraphic communication, applicable especially for telegraphing to light-houses, either floating or on rocks at a distance from the shore, or for telegraphing to and from vessels. Wiloughby Smith, 24, Southampton buildings, London, W.C.

AUGUST 2, 1887.

10,659. Improvements in converters. William Phillips Thompson, 6, Lord-street, Liverpool. (Gustave Louis Robert, France.)

FEBRUARY 13, 1888.

2179. Improvements in incandescent electric lamps. Marshall Wheeler, 18, Buckingham-street, Strand, London.

FEBRUARY 14, 1888.

2246. Improvements relating to dynamo electric machines. Henry Harris Lake, 45, Southampton buildings, London, W.C. (Rudolf Eickemeyer, United States.)

2250. Improvements in printing telegraphs. Jacob Hayes Lavelle, 24, Southampton buildings, London, W.C.

FEBRUARY 16, 1888.

2308. Improvements relating to dynamo electric machines. Carl Coerper, 45, Southampton-buildings, London.

NEW COMPANIES REGISTERED.

Tunbridge Wells Electric Light Company, Limited.—Registered by Van Sandau and Co. 13 King street, Cheapside, London, E.C. Capital, £300,000, divided into 6,000 shares of £5 each. Objects to carry on at Tunbridge Wells and elsewhere the business of an electric light company in all its branches, and, in particular, to construct, lay down, establish, fit, and carry out all necessary cables, wires, lines, accumulators, &c., and supply electricity to light the town of Tunbridge Wells and the neighbourhood thereof, and buildings and places, public or private, in the counties of Kent and Sussex. The first subscribers are:

H. E. Chatwynd-Stapylton, gentleman, 72, Warwick-square, London	10
W. H. Hodgkin, banker, Old Bank, Tunbridge Wells	1
G. Cheverton, chemist, South Lawn, Tunbridge Wells	1
E. Darnant, grocer, Pantiles, Tunbridge Wells	1
E. Waymouth, draper, 104, Calverly-road, Tunbridge Wells	1
Benjamin C. Coles, tailor, Tunbridge Wells	1
E. A. Hollingham, veterinary surgeon, Mount Zion, Tunbridge Wells	1

Until otherwise determined by the company in general meeting, the number of directors shall not be less than three nor more than seven. The first directors shall be appointed by the subscribers to the memorandum of association. The qualification of every director shall be the holding of not less than £50 in the stock of the company. The directors shall be paid out the funds of the company, by way of remuneration for their services, the sum of £50 per annum, and such further sum as the company in general meeting may from time to time determine, and such sum shall be divided amongst the directors as they may think fit.

Kensington and Knightsbridge Electric Lighting Company, Limited.—Registered by Deason, Gibson, and Medcalf, 4, St. Mary-axe, E.C., with a capital of £250,000, divided into 50,000 shares of £5 each. Object: to purchase or otherwise acquire all or any part of the shares, works, undertakings, business, property and liabilities in and of the Kensington Court Electric Lighting Company, Limited, and for such purpose to adopt and perform, with or without modification or alterations, an agreement dated March 23, 1888, and made between Granville Richard Ryder, on behalf of the shareholders of the Kensington Court Electric Lighting Company, Limited, of the one part, and Douglas Eyre, on behalf of this company, of the other part, or such other agreement in lieu thereof as shall, in the judgment of the directors of the company, be expedient, with the object of acquiring the undertakings of the said Kensington Court Electric Lighting Company, Limited, and to make other similar agreements in addition thereto, to generate, produce, store, accumulate, and distribute electricity, electromotive force, or other similar energy for the purpose of lighting streets, public places, public or private buildings, manufactories, mines, ships, lighthouses, railways, tramways, and other places or things, and for the purpose of supplying motive power or heating in all or any of the before mentioned places or things, or for plating, combining, separating, or otherwise working in metals, or for carrying out or facilitating mechanical operations, or for any other purpose whatsoever which may be now known or hereafter discovered, and to form, establish, and maintain centres for such purposes, or any of them. The first subscribers are:

E. W. Cox, 11, Grayton crescent, Hampstead, N.W.	1
W. Escott, 9, Grove road, South Hackney	1
S. Jordan, 36, Gertrude street, Fulham-road	1
H. Gosson, 4, St. Mary-axe, E.C.	1
E. W. Lloyd-Hewell, Lancaster road, West Norwood	1
G. Hamlin, 43, Somersetton road, S.W.	1
B. W. B. Upl, 1, Finsbury-road, Uxbridge-road, W.	1

The number of directors shall not be less than three nor more than nine, and the following persons shall be the first directors, that is to say: Granville Richard Ryder, Alfred Selmer Belton, Sir Charles Grant, K.C.S.I., and Roger William. The qualification of a director other than the first directors shall be the holding of shares of the company of the nominal value of £100 at least: any director may at any time acquire his qualification. The remuneration of directors shall be determined in general meeting.

CITY NOTES.

Schanslioff Company.—The final batch of letters of allotment and regret in the Schanslioff Electric Light and Power Company were posted on the 5th inst.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the week ended April 6, amounted to £4 503.

Eastern Telegraph Co.—The Eastern Telegraph Company's traffic receipts for the month of March, 1888, amounted to £54,376, and to £49,797 in the corresponding period of 1887.

Notice of Removal.—We are informed that Messrs. W. F. Dennis and Co. have removed from 101, Leadenhall-street, to 11, Billiter-street, London, where all communications relating to their business should be addressed.

Great Northern Telegraph Co.—The receipts of the Great Northern Telegraph Company for March were £22,000, making a total from January 1 to March 31 of £63,800 against £61,200 and £58,680 for the corresponding months of 1887 and 1886 respectively.

Eastern Extension, Australasia, and China Telegraph Company.—The traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company for the month of March, 1888, amounted to £39,670, and to £38,177 in the corresponding period of 1887, an increase of £1,493.

Simplex Company.—At an extraordinary general meeting of this company on April 6th, it was decided that the company be wound up voluntarily, pursuant to the provisions of the Companies Acts, 1862 to 1886. Mr. A. H. Pownall, 69, Princess-street, Manchester, was appointed liquidator.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during March was 4,919, estimated to produce £3,800 against 4,775 messages, producing £3,727, in the corresponding month, of last year. The traffic receipts for December, estimated at £3,500, realised £3,373.

Western and Brazilian Telegraph Company.—At a meeting of the board of directors of the Western and Brazilian Telegraph Company, Limited, it was decided, after placing £15,000 to renewal fund, and £10,000 to debenture redemption fund, to recommend a dividend

of 9s. per share, free of income-tax, making, with the interim distribution, 4 1/2 per cent. for the year, against 3 1/2 for 1886. The receipts of this company for the week ending April 6, after deducting the £1,000 payable to the London Platino Brazilian Company, were £3,554.

Indo-European Company.—The board of directors of the Indo-European Telegraph Company, after adding £10,000 to the reserve fund, determined, subject to audit, to recommend the payment of dividend for the six months ended December 31, 1887, of 17s. 6d. per share, making, with the interim dividend already paid, 18s. 6d. per share for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year, carrying over £2,694 15s. 1d. The dividend and bonus will be payable on or after May 1 next. The Indo-European lines being now restored to the company is prepared to accept messages for transmission between the country and India, Penang, Singapore, China, Java, Australia, New Zealand, Persia, and Turkey.

The Oriental Telephone Company.—The report of the directors of the Oriental Telephone Company (Limited), for the year ended 31st December last, states that the revenue for the year exhibits a balance to credit of £5,854, which has been transferred to the profit and loss account. To this amount has to be added the sum of £4,760 brought forward, making a total of £10,614. In accordance with previous balance-sheets, the Indian guarantee for the year, viz., £2,406 has been debited to this account. The directors have deemed it advisable to reduce the item of preliminary expenses, and have consequently written off a sum of £1,128 in respect of these. They have further written off £259 for depreciation of stores in the various branches, the £121 in final settlement of losses on shipments of instruments to Australia on joint account, dating from 1880, with the Consolidated Telephone Construction and Maintenance Company, Limited. The net balance, therefore, to credit of profit and loss after deducting the above items, is £6,708. The directors recommend a dividend for the past year of 2 1/2 per cent., free of income tax, to be paid-up capital of the company other than the vendors' shares. This will absorb £3,106, and leave £3,602 to be carried forward. The report adds, the Telephone Company of Egypt continues to make satisfactory progress, and the dividend of 6 per cent. declared by that company for the past year on its preferred capital has been brought into the present accounts.

NOTES.

Barmen.—The number of installations is here 28, comprising 226 arc and 2,251 incandescence lamps.

Crefeld. There are in this town 14 private installations, comprising 175 arc and 3,209 incandescence lamps.

Dresden. There are here 30 installations of electric lighting, comprising 157 arc and 2,379 incandescence lamps.

Taunton. The motion for the extension of the electric light in the streets at the last meeting of the Town Council was defeated by a small majority.

Berlin.—This city, which possesses the greatest number of central and particular lighting stations, contains 1,650 arc and nearly 26,000 incandescence lamps.

Breslau.—The Municipal Council is taking steps for the construction of a central station. The number of particular installations is 27, with 123 arc and 1,933 incandescence lamps.

Cologne.—The construction of several central stations is here under consideration. There are already 33 installations of electric lighting, comprising 101 arc and 2,727 incandescence lamps.

Baden-Baden.—The first electrical project at this place is to be the lighting of a new sanatorium by 300 incandescent and seven arc lamps. The work will be carried out by Th. Wechsler and Co.

Society of Arts.—A paper is announced to be read on Wednesday, May 6th, by R. E. B. Crompton, on "The Electric Lighting from Central Stations," when the Attorney-General (Sir R. E. Webster, M.P.) will preside.

H.M.S. "Victoria." This vessel, built by Messrs. Armstrong, Mitchell and Co., has come round to Chatham for completion. The vessel is lighted throughout by electricity, and the guns are fired by the same means.

Society of Telegraph-Engineers. The paper to be read at the meeting of the society on Thursday next, April 25th, is by Mr. W. H. Preece, F.R.S., past president, "On the Risks of Fire Incidental to Electric Lighting."

Electric Lighting Act. It will be seen from the report in another column, for which we are indebted to the *Times*, that the Electric Lighting Act, 1882, Amendment (No. 2) Bill was read a second time, in the House of Lords, on Tuesday.

Varzin.—Prince Bismarck's paper mill at Varzin, which was burnt last year, has been rebuilt at a cost of £50,000, and it is now one of the largest and most complete establishments of the kind in Germany. It is lighted throughout by electricity.

Festival Lighting. The electric lighting of the Palais de l'Industrie on the occasion of the *exposition* on the 17th instant, was entrusted to M. H. Fontaine, who is president of the syndicate for the lighting of the Universal Exhibition of 1889.

Transformers.—The installation for the electric lighting of the town of Temesvar, in Hungary, is to be modified by the introduction of alternating machines and transformers. The latter are to be supplied by Messrs. Kromenzky, Mayer and Co., of Vienna.

Accumulator Patents.—The action taken by Messrs. Philippart Bros. against manufacturers of secondary

batteries in Paris, which was referred to in a note in these columns last week, had been, according to the *Bulletin de l'Electrote*, threatened for some time past.

Hastings. At the last meeting of the Council, a long discussion took place upon the report of the Lighting Committee, which had referred to it last December questions relating to the obtaining of independent tests as to the illuminating power of the electric light. The committee reported in favour of no steps being taken at present.

The 1889 Universal Exhibition.—The International Syndicate for the electric lighting of the Exhibition have elected as director M. de Boret, mining engineer; as chief engineer, M. Picou, manager of the works of the Continental Edison Co.; and as inspectors, MM. Napoli and Dumont, engineers of the Compagnie des chemins de fer de l'Est.

Tenders Required.—As will be seen from our advertising columns, the House to House Electric Light Supply Company, Limited, invite tenders for the supply of steam engines, boilers, and electric machinery. The specifications will be open for inspection at the offices of the Company on and after the 23rd inst.; but means have been taken to prevent its perusal from mere idle curiosity.

Munich.—Although no central lighting station has hitherto been constructed in this town, it includes forty-three establishments lighted by electricity, representing a total of 167 arc and 7,936 incandescence lamps. Besides these there are 2,300 incandescence lamps in the Imperial Theatre, 800 at the Ministry of War, a considerable number in the Chambers, and others in the markets on the quays.

Trouve's Auxanoscopes.—This apparatus, which will probably be most useful for lecturers to popular audiences, is an electrical magic-lantern, which produces an image upon a screen by reflected or by transmitted light, or by both combined. It possesses the advantage of not requiring a very powerful luminous source: an incandescence lamp that can be worked by a few bichromate cells suffices to give a satisfactory result.

Cheap Curative Electricity.—One of the telegraph lines on the Wabash road, known as number four, has been a source of mystery to the operators for some time. It had spasms of going and stopping, and "old climbers" has been unable to locate the trouble until quite recently. He finally chased it down to where an old man had led a wire into his house near Wabash, Ind., and was applying electricity for the cure of rheumatism.

Incandescence Lamps. It is stated that the new apparatus supplied by Messrs. Fritsche and Fischon, of Berlin, to the company in that city manufacturing the Seel lamps, considerably reduces the period necessary for the production of a vacuum by the Sprengel pumps hitherto used. The company is about to enlarge its works in consequence of the favourable reception of the Seel lamp in Germany. The lamp is stated to be very economical in working.

From America. We have received from our contemporary, *Modern Light and Heat*, a neat little pocket-book filled with squared paper, suitable for graphic diagrams or notes. In addition to the paper, there is a printed slip containing some twenty-eight definitions, formulae, and things to be remembered connected with electrical engineering.

ing. The whole is "with the compliments" of the paper. Duplicate books to fit the covers are promised by our go-ahead contemporary.

The Pervasiveness of Lightning. A correspondent of the *Springfield Republican*, describing the effects of a recent lightning stroke, says that "the ceiling of the room had been replastered the preceding spring, and the sand of this locality, which is used in mortar, is ferruginous. Every metallic particle in the latter the fluid seemed to have found and detached, so as to give the plastered surface an appearance better described as pock marked than by any other words at my command."

Leamington. At a recent meeting of the Leamington Town Council, an account for £96. 5s. from the Electric Lighting Co., being the quarterly charge for supplying the electric light to the Parade, was passed for payment by the Finance Committee. It was stated that the sum now paid for the electric light is about double what was paid for gas for the same quarter of the town; but that there were twice the number of lights. Presumably, there would be much more than twice the quantity of light.

Dublin.—The Dublin Corporation announce that they have applied to the Board of Trade for a licence to supply electricity for all public purposes within that city. The applicants do not propose to take powers to break up any streets not repairable by the local authority, nor any railway; but they propose to be empowered by the licence to break up the tramways belonging to the Dublin and Lucan Steam Tramways Company, and those belonging to the Dublin United Tramways Company. They also propose to cross the River Liffey.

Lady Telephonists.—The following is from the *New York Electrical Review*:—"New York City, we venture to say, has the best-natured and most tactful staff of telephone operators in the world. During the great storm, with all its exasperations and unlooked-for annoyances, the young lady operators were always accommodating, endeavouring in every way to aid the subscriber in securing answers to his calls. Manager Lockwood and his gentle-voiced staff may well be proud of their excellent work during and following the blizzard."

Water-Level Indicator for Steam Boilers.—At the last meeting of the Franklin Institute, Philadelphia, Pa., Mr. Morris P. Jauney described a new electrical water-level indicator for steam boilers, by Charles Wickersham, of Pottstown. It is a device which will constantly indicate by means of a dial and index the height of water, and shows its rise and fall in inches and fractions. Attached to it is an electric annunciator, with visible and audible signals, for indicating at any distant point the variation of water level in the boiler beyond the prescribed limits.

Church Lighting. The parish church of Blockley, a large village on the southern border of Worcestershire, is shortly to be lighted by electricity. The installation is being carried out by a company, who have taken some old mills near at hand for manufacturing purposes, and the machinery will be driven by water-power, of which there is an abundance available. This is by no means the first church that has been illumined by electricity, and we were recently informed that, in China, the Governor of Tamsui has had his Yamen lighted by the same agency.

Lecture Lantern.—An improved form of lantern for the projection of photographic and other slides on to a screen, has recently been supplied by Messrs. Drake and

Gorham to the Royal Society, to which institution this firm act as electrical engineers. This lamp, in addition to the condenser and ordinary lenses, has been fitted with a special prism arrangement for projecting horizontal surfaces on the screen. The lantern is fitted with a Brockie-Pell arc lamp, which burnt remarkably steadily at the recent Bakerian lecture given by Mr. Norman Lockyer, when the plant was run for the first time.

Hamburg. There are in this town 70 establishments lighted by electricity, comprising about 300 arc and 4,500 incandescence lamps, besides two central stations, and one in course of construction, each supplying 1,000 lamps. Since 1882 the Municipal Council has had a central station for lighting the Senate House with the adjacent buildings, the square of the Hotel de Ville, and three warehouses. The Council now propose to establish a central station supplying 10,000 lamps, and capable of working double this number. In the warehouses of the Free Port there are, moreover, 50 arc and 4,000 incandescence lamps, and several electric lighting projects are under consideration.

Breslau.—A committee, says *Industries*, appointed by the Town Council to inquire into the best means of installing the electric light in the town, has reported in favour of a large central station to supply 5,000 lamps, distributed throughout an area the boundary of which is at no point farther than 1,200 metres from the generating station. It is not intended to ask public tenders for this installation, but to entrust it to Messrs. Siemens and Halske, of Berlin, who will submit an estimate based upon a general plan of the district. The management of the central station will be in the hands of the Municipality. These recommendations of the committee have not yet been finally adopted.

Paris-Lyon-Marseilles Telephonic Line.—The Prefect of the Department of the Rhone has communicated to the Lyon Chamber of Commerce a letter, in which the Director-General of Posts and Telegraphs announces that the work in connection with this line will probably be completed within two and a half months. It is probable that communication will be established between Lyon and Marseilles about the middle of next month, and between Lyon and Paris about the middle of June. In regard to the proposed line between Lyon and St. Etienne, the offer of the Lyon Chamber of Commerce to advance the sum necessary for its establishment, with a view to obviate any delay in commencing the work, will no doubt be accepted.

Legal.—The great lamp case between the Edison-Swan Company and Mr. Holland, or rather between the former and the Brush Company, has been proceeding during Tuesday, Wednesday, and Thursday of this week, and will be continued on Monday next. The opening for the plaintiffs and the evidence in their favour is very similar to what has been put forward in previous cases, and we think has no very great interest for our readers generally. It is said that the defendants have some new evidence to bring forward, and this will probably form the most important feature of the case, except the judgment. Of course, the greatest interest will centre in the latter. For the present it is absolutely impossible to foretell what this will be, and patience must be exercised for some days to come.

Electric Lighting in Germany.—At a recent meeting of the German Association of Gas and Water Engineers, a report on the position of electric lighting in

Germany was read by Dr. Shilling, who pointed out that, although the new illuminant has been most largely adopted outside of the circles of distribution supplied by the gas companies, it must be admitted that it had also made notable progress in several cities supplied with gas. Taking an aggregate of thirty large towns, the number of establishments lighted by electricity had augmented in the course of the two last years from 138 to 604, the number of arc lamps from 591 to 3,280, and that of incandescent lamps from 10,403 to 50,469 amounting to about 4 per cent of the number of gas-burners in the same towns. The present position of electric lighting in some of the largest of these towns will be noted under their respective names.

Weston-super-Mare. Agitation is still going on to obtain the electric light. At the last meeting of the town authorities a letter was read from Dr. Wicksteed, as follows:—"May I ask of you, in the name of a very large and influential body of ratepayers (whose interests I have frequently represented at your monthly meetings), what steps your Board propose taking as regards the adoption of the electric light for public and private purposes in the town? The season will soon commence. The public want the light. Pray enlighten them. The illness of my son takes me away from home for the next three weeks, therefore I should be glad if your answer to this note could be a public one." Mr. Knight said the Board had thought the matter over, and they had been waiting until the new Board had been elected. After this had been done it would be well to appoint a committee to discuss the subject: in fact, there was a resolution down to that effect.

Contact Electricity.—Exner's recent researches in support of his contention that there is no such thing as contact-electrification were founded on his experimental results, that if an insulated conductor be connected with an electrometer, and the latter then disconnected from the earth, and if the capacity of the conductor be then altered, the electrometer will remain unaffected; whereas, according to the contact theory, there should be a flow of electricity. The conclusion of Exner has been objected to by Hallwachs, but Exner is still inclined to support his own opinions, and states that the objections raised against them do not carry any weight. He claims that no change is produced when the grating is brought into contact with a conductor consisting of a different metal; such a change is required by the contact theory. He has not attempted to determine whether it would be required by the chemical theory, nor, so far as he is aware, has the question been considered by others.

The Electric Light in Italy. The central station at Terni, which was completed in February last, is capable of supplying 3,000 incandescence lamps of 16 c.p. The works comprise three groups of machines, each composed of a Girard turbine of 150 h.p., an alternating current dynamo of 2,000 volts and 40 amperes, and the means for exciting the latter. The works are established outside the town, at 200 metres from the walls. The current is distributed by means of 21 Ziperowski transformers, each of 7,500 watts, the tension of the secondary current being 100 volts. All the conducting wires are uncovered and overhead. Besides the lighting of private houses, the station supplies the public lighting of the town, maintaining 350 incandescence lamps, of which the candle-power varies from 10 to 50, and which are charged for at the rate of 4 to 13 centimes (4 to 13d) per hour. Electric lighting has been recently introduced in the towns of Arellino and

Omegna. The Arellino station, which is by far the more important, is capable of maintaining 2,500 incandescence lamps.

Properties of Molten Silver.—At a recent meeting of the Société Française de Physique, M. Violle made known the results of his researches on this subject. He in the first place examined into the emission polarisation which was pointed out by Arago, but which has recently received but little attention, probably by reason of the difficulty of a clear incandescent surface. The photopolarimeter of M. Cornu exhibited a polarisation increasing regularly from 0 to 80 degrees. The proportion p of polarised light contained in the beam from the molten metal is 0.17 under an angle of 30°, 0.33 under an angle of 45°, 0.55 under an angle of 60°, 0.77 under an angle of 75°, and 0.84 under an angle of 85°. The results of observation are expressed by the following formula:

$$p = (1 - \cos i) \left(1 + \cos 75 + \frac{i}{5} \right).$$

In the second place M. Violle sought to compare the total energies respectively radiated by silver and by platinum at their temperatures of fusion. By means of a thermobattery he found that the total radiation from melting platinum is 54 times that from melting silver. The ratio of the luminous intensities is 20 times greater.

Illumination. We translate the following from the *Fundamentale* of M. Hospitalier:—The illumination produced at a given point by a luminous focus is the quotient of the illuminating power of this focus by the square of the distance from it of the point in question. The practical unit of illumination is the *candle metre* or *candel-metre*, i.e., the illumination produced by a standard candle or a carcel burner placed at the distance of a metre. From 20 to 30 candle metres of illumination are required at any point to constitute a sufficient light, and at least 30 candle metres are required on a reading table to avoid fatiguing the eye. The illumination produced by a source of light is proportionate to the intensity of this source and inversely proportionate to the square of its distance from the point to be illuminated. Consequently, illumination should be expressed, not in candle-metres or carcel metres, but in *candles per square metre*, or in *carcels per square metre*. The light radiated by a candle through a sphere of 1 metre radius is distributed over a total surface of $4\pi r^2 = 12.6 \text{ m}^2$; the illumination is therefore 12.6 times less than if the whole of the light produced by the candle illuminated a surface of 1 m^2 at a distance of 1 metre. The candle per square metre is consequently a unit 12.6 times greater than the candle metre. An illumination of 1 candle per square metre is requisite to enable one to write as easily as in daylight.

St. James' Vestry. At the meeting of the Vestry on April 12, the Lighting Committee recommended that the consent of the Vestry be given to the St. James' and Pall Mall Company, but after a considerable discussion the matter was referred to a committee of the whole Vestry for further consideration. This was at the instigation of a Mr. Winnett, who wondered why electric lighting companies desired a particular part of the parish to light. Mr. Winnett's arguments against permission by the Vestry were of the usual stereotyped, pig-headed, John Bull type. Some one else had spent a lot of money, and failed. *ergo*, the present company must also fail. We know nothing of the companies referred to one way or the other, but we do know this, that no argument of such a kind is worth a

moment's consideration. We do not hold that a vestry should consent at the first request, but surely if the matter has been referred to a committee, and that committee has made due inquiries as to the plans of the company, and reported favourably, it seems absurd that another committee should have to go over the same ground and do the same work over again. The vote of the Vestry is simply this: we form a committee consisting of certain men to do certain work, because we thought them capable of doing that work satisfactorily; but now they have done the work, we say they were incompetent, and the work must be done over again. Is not this a fine example of Bumbledom?

Portable Electric Lighting Apparatus.—The apparatus constructed by Ganz and Co., of Buda-Pesth, to facilitate the movement of troops by railway transit during the night has been found very serviceable during certain manœuvres in South Eastern Hungary, on the frontier of Roumania. Its main purpose is to avoid confusion at railway stations on the occasions of the embarkation or arrival of large bodies of men. It comprises a transportable steam-engine of 8 h.p., in the rear of which is located an alternating-current dynamo machine of the Zipernowski pattern, capable of working eight arc lamps, each of 600 candles. A van, somewhat similar to those employed for the transport of furniture, carries, in addition to the lamps and their supports, the posts which are to carry the line, 2,000 metres of wire coiled on a drum (which is mounted upon a carriage), the necessary tools, and two water tanks for the supply of the engine. Both the engine and the van are constructed to be readily transferred to railway platform waggons, and thus transported by rail. On arrival at a given railway station, some of the workmen erect the posts and locate the lamps at the points indicated to them, whilst the engineer is getting up steam. Less than seven hours suffice for the installation, by eight workmen, a fitter, and an engineer, whilst the whole apparatus can be dismantled within five hours. The cost of the lighting for the eight arc lamps, during ten hours, was 17.5fr.; the whole apparatus costing about 21,000fr.

Photochronoscopic Method of M. Hermite.—To obtain a distinct photograph of an object moving with great velocity, as, for instance, a rifle bullet travelling at the rate of 400 metres (1,304ft.) per second, is *prima facie*, and from the popular point of view, a somewhat difficult problem. It has been very neatly solved, however, by M. Gustave Hermite, under the condition that the object must be in darkness. He simply illuminates it by the spark from an induction coil. The sparks from this instrument occur at perfectly regular intervals of time, so that the only practical difficulty in carrying the suggested means into effect is to accurately measure the duration of the interval. This, M. Hermite has accomplished by the use of a diapason, of which the number of vibrations per second is accurately known, and which is simply a thin strip of steel fixed in a metallic holder. It is set in vibration by bending it with the finger. If now it be illuminated by sparks from a Ruhmkorff coil, and the number of vibrations of the strip happens to be equal to that of the sparks, the strip will be seen in a position of inclination. If the number of sparks be double that of the vibrations, the strip will be seen in the form of a V. If there be discord between the numbers, the branches of the V will appear to close and then to open again. It will be seen that these phenomena afford a means of regulating

the coil so that it may give a determinate number of vibrations and sparks per second; and the means in question are found to be very practical and very accurate.

Incandescence Filaments.—Some interesting observations relative to the carbon filaments of incandescence lamps have recently been made. In testing chemically certain filaments said to be of a material other than carbon, Mr. Desmond Fitz-Gerald boiled them in strong sulphuric acid, with the view, if carbon were present, of obtaining carbonic oxide and sulphurous acid according to the reaction

No such reaction occurred; the filaments in question remaining unaltered. Before committing himself, however, to the conclusion that no carbon was present, the experimenter took the precaution of repeating the experiment with filaments known to be of carbon. These filaments also remained unaltered after prolonged boiling in the acid. This result justifies the conclusion that the carbon of lamp filaments, unlike ordinary carbon, is not acted upon by sulphuric acid at its boiling point. It confirms also the conclusion arrived at by Mr. Anthony, that the molecular constitution of a filament of carbon, obtained by heating to redness a filament of organic matter, becomes modified when the material is subjected for a certain period of time to the comparatively high temperatures obtained by its incandescence as a lamp-filament. Mr. Anthony found that this molecular change is indicated by an increase in the specific resistance of the carbon. Operating with a new filament, he observed that a diminution in its resistance occurred at a comparatively low temperature, and that the resistance steadily diminished as the temperature was augmented. But after the filament had been allowed to cool, its initial resistance was found to have augmented. The same fact has been observed by other investigators, but one of Mr. Anthony's results is probably altogether novel. Operating with certain incandescence lamps taking currents of 6, 8 and 10 amperes, and giving luminous intensities of 32, 65 and 125 candles, he found that the resistances of the filaments had appreciably diminished after the lamps had been working for from 200 to 300 hours, and that subsequently the resistance steadily increased up to a certain point as the working was continued.

Bath. At the meeting of the Bath Town Council, the most important item on the agenda was: "To receive a report from the committee appointed on the 2nd of August last to consider the question of lighting the streets of this city with the electric light." The report simply stated that the committee had made enquiries of other towns where the light had been adopted, and awaited further instructions. The Town Clerk said before they proceeded, he would read a clause from the Municipal Corporations Act. It was as follows: "A member of the Town Council shall not vote or take part in the discussion of any matter or matters in which he has, directly or indirectly, by himself or by his partner, any pecuniary interest." Mr. Comman said he could not accept that ruling. If shareholders in the gas company or electric lighting company could not vote, then half the Council were debarred, which was ridiculous. Alderman Chaffin, as one of the directors of the gas company, could not conceive anything more cruel or more unjust than that the mouths of those who happened to be shareholders, or interested in the gas company, should be closed, and that they could not point out, as ratepayers, the disadvantages of any new system

SAINT-ETIENNE CENTRAL LIGHTING STATION.*

BY HYPOLYTE MONTAIGNE.

The works installed at Saint Etienne for the electric lighting of the central portion of the town by the Edison system are shown in the accompanying illustrations. Figs. 1, 2, 3, and 4 relate to the machine room, and Figs. 5, 6, 7, and 8 to the mode of grouping the dynamos and to the switch board arrangements.

The Edison Electrical Company of Saint Etienne was established in May, 1885. Its works, which were initially designed for the supply of 1,100 amperes, were inaugurated five months afterwards. By successive developments they have now been made capable of supplying 2,600 amperes.

The light is supplied at the price of 6 centimes (3d.) per lamp hour of 16 candles. The charge made is by meter, but each client pays an annual fixed sum of 3fr. 50 centimes (2s. 11d.) in addition to the price of the current supplied.

The works are situated in the very centre of the town, in a yard having an area of about 300 square metres (about

pendent Koertling injectors and a supplementary donkey engine. The escaping steam, even that which may pass from the safety-valves, is collected by a cast-iron pipe, and used to heat the feed water. The system of steam-escape is so arranged that, by turning a valve, the steam may pass direct to the shaft or to the feed water. The engines, like the boilers, are four in number. They are high-pressure compound tandem engines. The slide-valves are rotary, on the Corliss system, with expansion gear regulated by hand. The cylinders are 280 (about 11in.) and 420 (about 16.5in.) millimetres in diameter, with the same stroke of 600 (2ft.) millimetres. The cranks make 160 revolutions per minute. The consumption is about 10 kilogrammes (22lb.) of steam per h.p.

At the pressure of 6 kilogrammes each engine normally develops from 70 to 75 h.p. effective. At the pressure of 11 kilogrammes, from 180 to 190 h.p. effective can be obtained.

The steam cylinders are, of course, steam jacketed.

The engines are each provided with two fly wheels, one at each extremity of their crank-shafts. The fly wheels

FIG. 1.—Section on A B.

A Boilers. E Engines. F Intermediate Shafting. G Protecting Wall. H Edison Dynamos.
T Cable from Dynamos to Collectors.

360 square yards). Owing to the limited space at disposal, a special arrangement has been adopted. The boilers are placed at the level of the soil, and the walls separating them serve as foundations for the engines. These walls, in which are contained the flues (vide Fig. 3), rise about 2m. (6.4ft.) above the boilers. On the other hand, the protecting wall, constructed in accordance with the official regulations for the protection of the adjoining property, serves as a foundation for a portion of the dynamos.

On the level of the summit of the flue-walls is the flooring of the dynamo room. The means of transmission are arranged within the space of 2 metres (2 yards 7in.), between the top of the boilers and the flooring of the machine-room.

The means for generating steam consist of four boilers with interior fire-boxes on the Farcot system, having 90 square metres (about 1,100 square yards) of heating surface. The flue receiving the smoke is situated at the base of the protecting wall, and communicates with a shaft, 45 metres high, placed at the angle of the works. The boilers are supplied with water by means of two inde-

pendent Koertling injectors and a supplementary donkey engine. The escaping steam, even that which may pass from the safety-valves, is collected by a cast-iron pipe, and used to heat the feed water. The system of steam-escape is so arranged that, by turning a valve, the steam may pass direct to the shaft or to the feed water. The engines, like the boilers, are four in number. They are high-pressure compound tandem engines. The slide-valves are rotary, on the Corliss system, with expansion gear regulated by hand. The cylinders are 280 (about 11in.) and 420 (about 16.5in.) millimetres in diameter, with the same stroke of 600 (2ft.) millimetres. The cranks make 160 revolutions per minute. The consumption is about 10 kilogrammes (22lb.) of steam per h.p.

At the pressure of 6 kilogrammes each engine normally develops from 70 to 75 h.p. effective. With this view the shafting is in sections, and can be connected as required by clutches.

Flat pulleys are used, 900m. in diameter (about 1yd.). All the pulleys have friction clutches, and can be thrown in or out of gear as required. In this manner the dependence or independence of each engine and of each dynamo is in great measure obtained at will.

The distribution is effected by three conductors at from 225 to 230 volts at the terminals.

The dynamos are seven in number. The type initially

* Translated from the *Revue Industrielle*.

tested, when the output was only 1,100 amperes, was that it was necessary to adhere to the original design. The dynamo is mounted on rails and can be shifted by means of screws when it is necessary to tighten the

FIG. 2.—Plan of Installation.

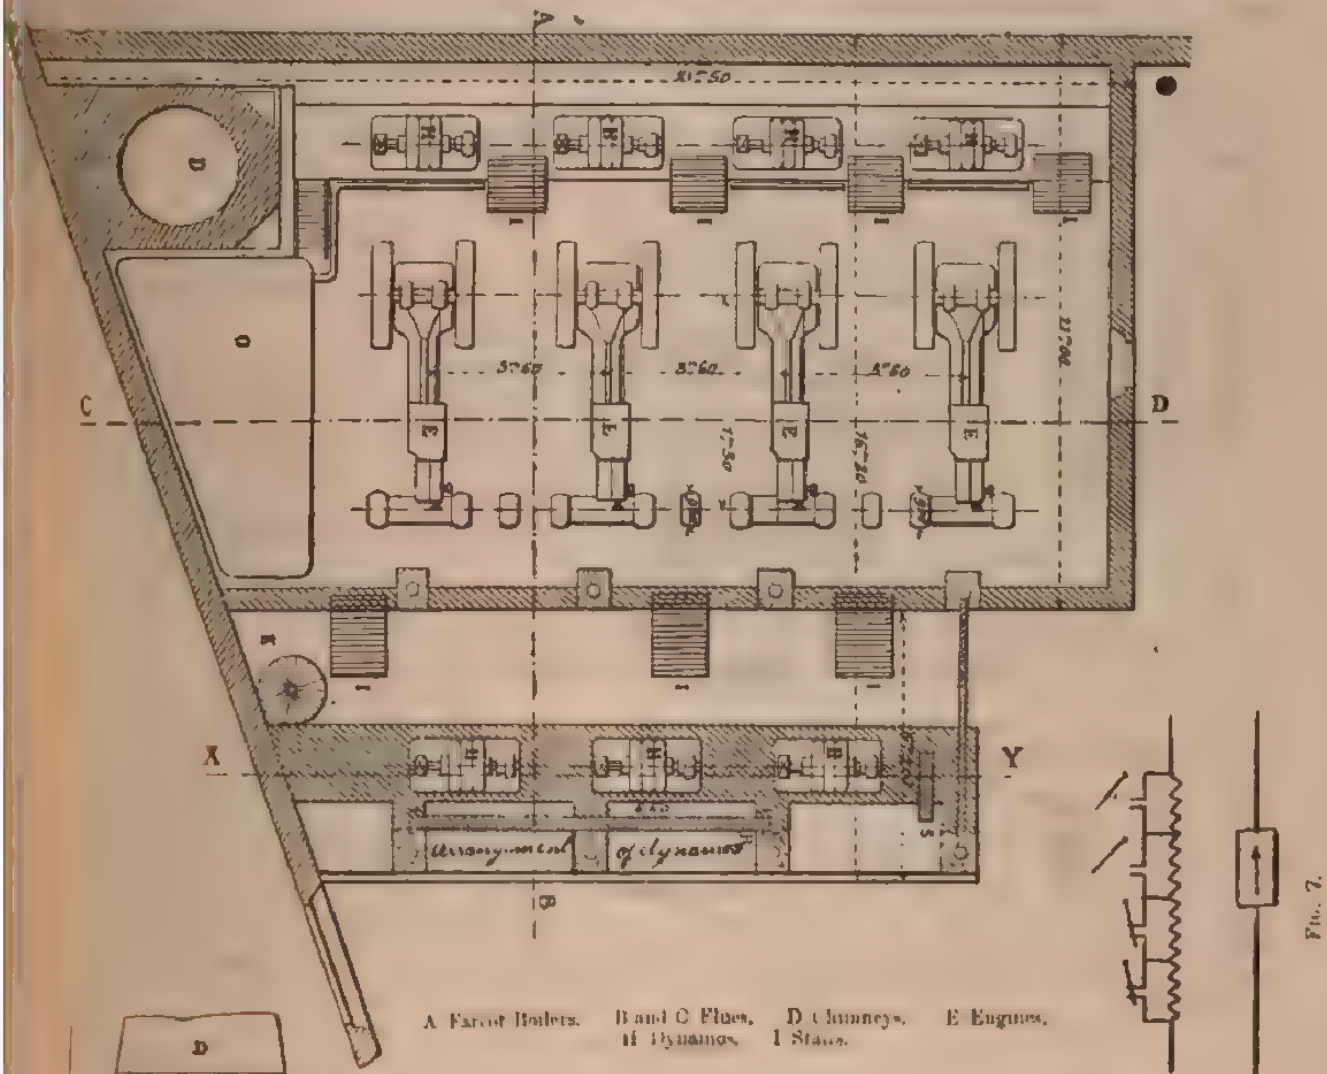

FIG. 3.—Section on C D.

It was when the works were extended, in order to maintain uniformity of yield, and to allow of easy grouping for quantity belting. The magnetic field is generated by a group of three electromagnets, each having two arms, or altogether by six

coiled arms, connected in two series of three in multiple arc. The exciting current has an E.M.F. of 220 (1240) volts. Each of these having a resistance of 45 ohms, the joint resistance of the whole is 33.75 ohms (130 ohms), and the current consumed is $\frac{220}{33.75} = 6.5$ amperes nearly.

The armature is of the ordinary form in Edison machines. Its internal resistance when cold is 0.01 ohm only; whence it follows that the E.M.F. absorbed in the interior of the machine is very small, and that the total efficiency of the dynamos is very high.

The arrangement contrived by M. Ebel will be readily understood by referring to the details of a switch box (Fig. 5) and to the sketch (Fig. 8).

The dynamos A and A₁ are connected in series by means of the circular commutators, 1, 2, and 1₁, 2₁. These commutators are all provided with notches in the arc of a circle the object of which is to prevent the simultaneous action of two adjacent commutators. Each commutator carries two contacts, A and B, which serve to complete the circuit of the dynamo and of the network.

After turning the commutator 1 of dynamo A, so as

FIG. 5.—Switch and Regulation Board.

D + D- Positive and Negative Terminals. C Plug to Close Magnetic Field. I I Regulators (c. Fig. 8). R Resistance Magnetic Field.

The driving pulley, which is wedged on the armature shaft, is placed between two supports, an arrangement which is most favourable to the durability and proper working of the machine. The current is taken from the collector by three pairs of brushes. Leads connected to the terminals are taken to the distribution-board (Fig. 5) of each dynamo.

connect the latter to the network (+1) it is impossible to turn the commutator 2 of the same dynamo, since it becomes locked by the notch of the former.

To connect the dynamo A₁ in series with the dynamo A, all that is required is to close the commutator 2, which puts A₁ on the network (1-), and the commutator 2 no longer act.

FIG. 6.—Arrangement of Dynamo Connections.

A Ammeter. R Resistances. I I Switches for putting Dynamo Current on one or other Network (c. Figs. 5 and 8 for details).

The connecting boards for the dynamos are so designed that any one of the latter may be employed in substitution for another on either of the networks of the system of three conductors without any fear of short-circuiting the dynamos, or placing them in derivation under 200 volts. This is due to the gearing arrangements of the accumulators patented by M. Ebel, the manager of the Edison Electric Company, of Saint-Etienne. By this system an inversion of the intended arrangements is automatically rendered impossible, and the due preservation of the generators and utilizers of the electric current is assured.

If it had been wished to couple the two dynamos in multiple arc, the commutator 1₁ would have had to be closed.

Besides these contrivances, there is other locking gear which prevents the commutators from being closed prior to the excitation of the magnetic fields, and, conversely, to prevent the magnetic fields from being cut off prior to the interruption of the external circuits of the dynamos.

At starting, the distribution had been established with two conductors; the leads resting on glass cubes in blocks of cement. But when the network was extended, the Edison system, with three conductors, was adopted.

the three conductors are round bars of copper, separated by each other by wood blocks soaked in paraffin, the whole being enclosed in iron tubes filled with resin.

The copper bars project a few centimetres beyond the ends of the tubes, and are connected by soldering to them in copper cylinders. The ends are enclosed within a mass of cement, into which also melted resin is run.

The four feeders have the following lengths and sections:

No.	Length in metres (39 37in.)	Section of positive and negative (sq. mm.)	Section of intermediaries.
1	375	415	200
2	222	255	143
3	520	490	255
4	700	710	415

The network, properly speaking, to which the lamps are connected, has a total extent of nearly 5,000m., about 40 yards. It has been constructed with conductors of different sections, according to the current and E.M.F. required. One of these types consists of a positive and negative of 200 square mm. (about .3 square inches), with intermediate of 140 square mm. (about .2 square inches); another of a positive and negative of 140, and an intermediate of 100 square mm. (about .15 square inches).

FIG. 4. —Section on X Y.

The whole of the plant in fixtures, boilers, engines, dynamos, connection-boards, network, and branches cost approximately 500,000fr. (£20,000), for which sum about 10 lamps have been installed and motive power distributed.

The expenses of working bring the cost of the ampere-hour to 0.0325fr. (about .325d.) These may be taken as follows:—

Hour	0.009fr.
at the average price of 13fr. per 1,000kg.	0.01
variation	0.001
interference	0.0025
General expenses, water, rent	0.01
Cost of the ampere-hour	0.0325fr.
(or about .325d.)	

These figures are applicable to an annual production of about 1,500,000 ampere-hours for an average number of 10 lamps installed.

The above information has been obligingly supplied by Chataud, the manager of the Continental Edison Company at Paris. During a recent visit to Saint-Etienne, Gramme and M. Fontaine were able to verify their accuracy, and to satisfy themselves that the works are properly constructed with regard to safety and economy.

M. Ebel, the manager of the station, explained in detail the working of the apparatus, and especially that of the switch-boards devised by him.

THE VARIATION OF THE CO-EFFICIENTS OF INDUCTION.*

BY W. E. SUMPNER, B.Sc.

The co-efficient of self induction of a coil whose magnetic circuit is wholly or partially composed of iron is such a variable quantity, that it is necessary to define its meaning more exactly than has hitherto been done. Of the many definitions possible to give, the best is probably that according to which it is the ratio of the induced electromotive force to the rate at which the current is changing; since the induced electromotive force is equal to the rate at which the magnetism is in changing, the ratio in question is the rate at which magnetism changes with the current. From this it follows, that if a curve be drawn whose abscissae represent the current and whose ordinates represent the amount of magnetism or the number of lines of force enclosed by the coil, the co-efficient for any particular current will be represented by the rate of slope of this curve. The shape of these curves is well known from the researches of Prof. Ewing, Dr. Hopkinson, and others. They are generally such that, as the current increases, the curve slopes very gradually at first, but becomes steeper and steeper until the current begins to saturate the iron. The curve then bends over, and the slope becomes ultimately small. When the current is diminished, the curve of magnetism, owing to magnetic hysteresis, does not return on itself, but is such that it becomes steeper and steeper as the

FIG. 1.

current is diminished. Fig. 1 shows the general shape of the curve connecting the induced magnetism with the current. The arrows indicate the way in which the current is changing. Fig. 2 is a curve drawn from Fig. 1, and is such that the ordinate for any particular current represents the rate of slope of the curve in Fig. 1 for the same value of the current. The co-efficient of self-induction for increasing currents at first increases and then diminishes, while for decreasing currents it is small at first, and steadily increases as the current is brought to zero. Many experiments made on an electromagnet, on the field-magnets of dynamos, and on a Kapp transformer have completely con-

FIG. 2.

firmed these conclusions. Owing to magnetic hysteresis, the number of lines of force enclosed by the coil will depend not only upon the current flowing at the moment, but also on those that have been flowing previously. The value of the co-efficients will, for the same reason, depend

* Abstract of paper read before the Physical Society of London, April 14th, 1888.

* From the *Centralblatt für Bakteriologie*, No. 8, 1895.

diameter, and also to two insulators outside the waggon. From these last the connection to the lamps is always made.

At one end of each side of the waggon are placed, when out of use, the 8 arc lamps (8.9 amperes, 1,000 1,200 c.p., burning 8-10 hours). These are hung upon a specially contrived elastic frame, so that they may not be liable to damage from the vibration.

At the side of the waggon are two pulleys with windlasses mounted on brackets; on these are coiled the leading wires, which by this arrangement are easily paid out.

Compartments for fuel, oil, tools, &c., are also provided.

The stove hole is lined with strong sheet iron, all the rods are insulated, where passing through the waggon, with bakelite. Immediately below the boiler is a tank of sheet iron, containing about $1\frac{1}{2}$ cubic metres of water. A part of the exhaust from the engine goes into the tank to warm the water, the remainder goes into the chimney. During transit, or when not in use, the chimney can be lowered.

On the roof of the waggon, a place is also provided for each lamp-post during transit, one lamp post is arranged so as to be easily hoisted upon the platform of the waggon or let down again. The lamp on this lights the space around the waggon, thus forming a small station of light. On the lamp posts are two insulators, and two pulleys with steel wires to raise the lamps.

Fig. 1.

These lighting-waggons have the advantage that they can be put in use without delay, and the boiler can be heated during transit to the destination. For this purpose the chimney can be raised or lowered from the inside of the waggon by means of counterweights. There is nothing to do to the lamps but to hang them to the masts. The carbons can also be replaced without danger, as each lamp can be switched off without disturbing the others.

The interior of the waggon is lighted by two Edison glow lamps on brackets—one to the pressure-gauge of the boiler, and one to the dynamo.

For installation of the lamps in position three men are required: during use, one man.

SIR HUMPHRY DAVY, F.R.S.

With this issue we give a portrait, engraved on steel, of Sir Humphry Davy, who at the commencement of this century held the most commanding position of all England's scientific worthies. Humphry Davy was born at Penzance on the 17th of December, 1779. He was educated at the grammar schools of his native town at Exeter. At the age of fifteen he became the pupil of Dr. Borlase, of Penzance, with a view of entering the medical profession, and thus was led to begin the study of chemistry. While with Dr. Borlase, Davy made rapid progress, and entered upon a series of original investiga-

tions, the results of some of these appearing in a work published by Dr. Boddoo, who, noticing the talents of young Davy, obtained for him the appointment of experimental chemist at the Bristol Institution. Here he became acquainted with Davies Gilbus, who was afterwards President of the Royal Society. In 1801 Davy came to London, and on the 25th April in that year delivered his first lecture at the Royal Institution. The subject was Galvanism. In the month of May following he was appointed professor at the Institution, and at this period his work consisted largely in investigating electrical subjects. The results of his researches were first given to the world in his Bakerian lectures of 1807-1811, and were published in the *Philosophical Transactions* of those years. We shall not enter into the details of Davy's work. To him we owe the discovery of the decomposition of the fixed alkalis by electrolytic means. In fact, he may be said to be the father of the electrolytic branch of electrical science.

From the year 1808 to 1811 the following papers, of which he was the author, were read before the Royal Society and published in their *Transactions*.—"Electro-Chemical Researches and the Decomposition of the Earths, with Observations on the Metals obtained from the Alkaline Earths," and "On the Amalgam procured from Ammonia," read June 30th, 1808—

the Bakerian Lecture for 1809: "On some New Electro-Chemical Researches on Various Objects, particularly Metallic Bodies, from the Alkalines and Earths," and "On Some Combinations of Hydrogen," November 16th, 1809; "Researches on the Oxymuriatic Acid, its Nature and Combinations," and on the "Elements of Muriatic Acid, with some Experiments on Sulphur and Phosphorus," July 12th, 1810—the Bakerian Lecture for 1810; "On Some of the Combinations of Oxymuriatic Acid Gas and Oxygen," and "On the Chemical Relations of these Properties to Inflammable Bodies," November 15, 1810, and other papers. One of his greatest inventions was that of the miners lamp, the first paper in relation to which appeared in the volumes of *Transactions* for 1815, and the last in 1817.

Sir Humphry became President of the Royal Society in 1820, and he continued to contribute papers on subjects of great interest for some time. He was knighted on the 8th April, 1812 (afterwards created a baronet), and he died on May 12th, 1829, at Geneva. Bold, ardent, and enthusiastic, Davy soared to great heights of science; he commanded a wide horizon, and his keen vision penetrated to its utmost boundaries.

Leipzig. This town possesses two central stations and 21 private establishments lighted by electricity, together comprising 256 arc and 3,459 incandescence lamps.

THE ELECTRICAL ENGINEER.

Published every Friday.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom...	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places.....	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

Every Subscriber should with this issue receive a Portrait of Sir Humphry Davy, F.R.S., without extra charge, and failures to receive such Portrait should at once be notified to the Publisher.

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and this week we give that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

SHOP LIGHTING.

The owners of a large number of shops have already adopted the electric light, and many others are anxiously watching the time when they too may safely give their orders. We have within the past few days heard of a number of enquiries from tradesmen as to the first cost and the cost of maintenance of an installation. In most of the cases that have come before us the expected outlay is stated by the tradesman himself to reach from seven hundred to thousand pounds, so the enquirer does not wish to obtain his light for nothing. Most of our large electric lighting firms have agents in various parts of the country, but we venture to affirm that as yet no house has systematised its plan of agencies. There are not enough of them. It may be difficult to obtain agents of the right calibre, but nothing is ever done without trying. There is a lack of enthusiasm in the direction of small orders. Everyone wants "to bring the house down," that is, to make his reputation and fortune by handling some central station work. Depend upon it, unless the greatest care is exercised, good many fingers will yet be burnt before general success is achieved in central station lighting. There are hundreds, if not thousands, of electricians going about seeking whom they may devour, but there is scarcely a round dozen that understand the requirements, or could be trusted to satisfactorily design a scheme for the general lighting of a small town. If the larger number of the men who fly so high a game would only restrict their energies to those small works which their knowledge and ability would enable them to successfully grapple with, the result would be beneficial to themselves individually and to the industry collectively.

Another reason why so many are hankering over central station lighting is because they want to have a hand in the promotion of a company. Central station work will develop naturally; meanwhile, do not neglect the little orders. We are not writing for such firms as Crompton and Co. and The Brush Company. They and similar firms can undertake any work coming to them. We rather address ourselves to those we think are aiming too high. It will be as great a surprise to many of our readers as it was to us, to be told that a few weeks ago a tradesman who advertised for "electric lighting" was severely let alone by those who might have responded to his appeal. He is building a number of shops adjacent to a new one of his own, and by an arrangement with his tenants, present and prospective, has added a moderate amount to the ordinary rent for the purpose of providing the "electric light." Further, he requires an engine for his other work, so the matter is simplified to the installing a larger engine, dynamo, batteries, and fitting up the shops—outside with arc, inside with incandescence lamps. Two replies, and two only

WILLIAM H. MILLER LITHO, NEW YORK

Humphry Davy

were the response to the advertisement, and one of these was from a man utterly unknown in the industry; the other was from a young firm quite capable of doing some excellent work, and fully competent to undertake this special work. The tradesman, however, is used to the comparison of a number of tenders, but was quite at sea as to the value of the suggestions from the one responsible house. Quite accidentally, matters so happened that in all probability the work will be carried out; but no thanks will be due to the score or so of firms who ought to have been eager for such work. The capital of these firms is sufficient to enable them to carry out such work as this well, but insufficient for the larger work that lures them to destruction as the candle does the moth.

Further, in a great many shops there is an earnest desire to make the work as healthy and comfortable as possible under the exigences of modern business. It is, perhaps, a mistake to suppose that the hours are longer now than they were before the introduction of gas, but they have changed somewhat from early mornings to later evenings, and there is no reason to suppose the electric light would be required for fewer hours than is gas. In many cases, gas is far more costly than the shillings and pence per thousand paid for it lead one to suppose. The owners of the shops know this in the quantity of spoiled goods sold at a great reduction, and for this reason, among others, do not object to pay a higher price for a purer light. With regard to the number of hours, our contemporary, the *Warehousemen's and Drapers' Trade Journal*, has the following:—

"It is an unfortunate thing for tradesmen and their assistants," said an enthusiastic friend the other day, 'that gas was ever invented.' 'Why so?' we asked. 'Because,' he replied, 'before the introduction of gas for lighting purposes, shopkeepers acted upon the old maxim of "Early to bed and early to rise," but with gas came late and long hours and all their attendant evils, for which we find it so difficult to discover a remedy.' Probably the same conclusion has suggested itself to many of our readers, and if so, they may like to know how far it is correct, for few of us can remember much of business before gas lighting had become common. In the middle of the last century the draper's shop was supposed to be open from eight o'clock in the morning till dark, which would certainly give short hours in the winter and make them very long at midsummer; milliners, we are told, reckoned their hours to be from seven to seven, and mercers from eight to eight, while mantua makers (dressmakers as we call them nowadays) worked from seven in the morning till eight in the evening. Hosiers and haberdashers kept their shops open from seven in the morning to eight at night; while the grocers and oilmen, then as now, two of the special victims of long hours, were

expected to keep open from seven until ten o'clock, as also was the tobacconist. For most handicrafts the hours were longer than for tradesmen. The regular hours for tailors and breeches-makers were from six in the morning to eight at night; cap-makers, from six to nine; embroiderers, from six to eight; glovers, from six to nine; and for hatters, from nine in the morning to midnight! The regular hours for silk throwsters were from six to nine; and for weavers, generally, from six to eight o'clock. In the long list of trades and occupations before us (given in the 'London Tradesman' for 1751) the most common hours for artisans are from six to eight; though there are some curious exceptions besides those already noticed, as, for instance, the gunsmiths, whose working hours were from five o'clock in the morning to nine at night. It would seem, therefore, that upon the whole the introduction of gas has not had so marked an influence upon the length of business hours as might have been expected, and that, for the most part, closing earlier at night meant commencing earlier in the morning."

It may justly be said that these small installations cannot be as economical as larger ones, and especially will difficulties arise with the accumulators, as they require to be in charge of competent hands. Are the difficulties insurmountable or so great that contractors hesitate to dabble in such business?

THE EASTERN EXTENSION COMPANY AND ITS DIRECTORS.

Although we may be deemed impertinent in attacking directors and balance-sheets of old-established companies, we shall not hesitate to do what we believe to be a duty. It is but a short time since our new evening contemporary directed attention to stock-jobbing or speculation "masquerading in the guise of science." We have no objection to their masquerading in any guise they like, but it must be outside the City of London, and, indeed, outside English business of any kind. Nemesis comes slowly, but generally pretty surely; and it is high time a blow was struck at men whose action, judging from appearances, has always been to consider their own interests first and their shareholders after. The directors' report of the Eastern Extension Company has been issued. From one point of view it is good, in that it promises a six and a half per cent. dividend. From another point of view it is bad, in that the dividend, instead of being only six and a half per cent., should be higher. Our intention at the present moment is merely to cast a doubt as to the perfect bona fides of the directors. We want the shareholders to consider why the Eastern Extension exists as a separate company. A little examination will show that, so far as the clerical work of the Company is concerned, it is

carried on by the Eastern Company; that practically the line is an extension of the Eastern; that the interests of the two companies are so bound up together that they must be looked upon as one concern. The directors are, so far as influence goes, the same, but because they work the business as two separate companies they get a double amount in fees. Now, we contend that amalgamation would mean a considerable saving; and we are sure that if any change in the present administration should occur, amalgamation would be an immediate result. The shareholders, too, might make some pertinent enquiries about the reasons why no "managing director" was appointed after the death of the late managing director. The true reason is that the two parties most interested could not agree. One wanted the position for himself, the other wanted it for someone else. The time has not yet arrived when full light can be thrown upon other phases of management or mismanagement. We believe a great saving would be affected by amalgamation. We believe that the strained relations now existing between the companies mentioned and some of our colonies would cease under a change of management, and there are other reasons far more powerful which will compel a change. We believe that the shareholders could get a higher dividend, the public a cheaper and better service, were the whole of the questions relating to the success of these companies investigated. At the present time we merely point out that the amalgamation of the Eastern, Eastern and South African, and Eastern Extension Companies is becoming a question of urgency.

CORRESPONDENCE.

THE VAN RYSSSELBERGHE SYSTEM FOR TELEGRAPHS.

(Translated from the "Bulletin International de l'Electricité" for April 20th.)

"TO THE PROPRIETOR OF THE 'BULLETIN INTERNATIONAL DE L'ELECTRICITE'."

"SIR: In the number of March 26th of your valuable paper you state that the administration of the Swiss telegraphs has given up the Van Rysselberghe system on the line between Basle and Zurich, which had been fitted up as a trial, because the results proved entirely unfavourable.

"We do not know where you may have got that information from, since it is utterly wrong.

"We hold an attestation to the contrary from the chief of the Swiss telephonic network, the publication of which would occupy too much room in your paper, but which we hold at your disposal. It appears from the said document that the two telephonic communications between Basle and Zurich are working regularly.

"On the other hand, it is not on trial merely, as you seem to think, that the Van Rysselberghe system was applied to the telegraph lines between Basle and Zurich. Its success had long ago been proved in Switzerland. In fact, thanks to the initiative of the Administration of Telegraphs of that country, who had already commenced negotiations in 1883 with our firm for a proposed trial of the system, a telephonic and telegraphic service was opened between Lausanne and Geneva in 1884. At present, from

the last official statement, the Van Rysselberghe system is applied in Switzerland on 536 kilometres of telegraph wires.

"Trusting you will be kind enough to publish this correction in your next number. We remain, &c.,

"(Signed) "MORRISON AND CO.,

"Licensees of the Van Rysselberghe patents.

"Brussels, April 14, 1888."

[The above letter throws more light upon the subject of our note, p. 290, March 30. Ed. E.E.]

THE CHELSEA TENDERS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR: As it would appear from the account of the Borough Surveyor that although we are manufacturers of accumulator we do not ourselves employ them in our own electric light installations, we would point out that this is far from being the case; in fact, we were somewhat annoyed at the construction which had been put on our proposal, as we had gathered that the chief consideration with regard to the lighting was low first cost and economy of maintenance, and that an accumulator scheme was not wanted. Under the circumstances, we pointed out that it would be unsafe to rely upon one engine, and that a second would be necessary. Our estimate for maintenance was also made higher owing to the number of tons of coal, which we mentioned, being kept the same, whereas a better quality of coal was to be used. This would, of course, have materially reduced the consumption of coal for a given return, so that the coal should have been left as we put it in our estimate, when our maintenance would have come out £16 lower than given.

There is, of course, no question that a more efficient system of lighting would be provided by the adoption of accumulators, but the expense of the lighting would necessarily have been a trifle higher both in first cost and maintenance.—Yours, &c.,

DRAKE AND GORHAM.

LITERATURE.

Turning Lathes: A Manual for Technical Schools and Apprentices. A Guide to Turning, Screw-Cutting, Meta-Spining, &c. With 194 Illustrations. Edited by JAMES LECKER, B.A. [London: E. F. and N. Spon, 1884.]

The aim of this book is simplicity; and we think the author has succeeded in his endeavour to provide a work that shall describe simply the essential parts of a lathe and the way to use the machine. The book does not err, as so many do, in pretending to be written for beginners, and yet flying to the most difficult parts of the subject just to show the author knows all about it. The lathe in its simplest form is first described, then a number of the more useful chucks, after which the reader is told how to use the gouge and chisel upon plain solid work, and subsequently upon hollow work. Each successive chapter treats of more difficult and elaborate work, introducing, as required, descriptions and manner of using the various tools and lathe accessories needed for the work under consideration. The weakness of amateurs is not overlooked, for we read, page 33, "Where most amateurs fail is in the matter of patience." It is so. Instead of persevering to do the work with the simple tool, the amateur is on the look-out for this or that addition to his lathe to save himself trouble, and get the work done automatically. The professional, on the other hand, has plenty of patience; what he lacks is, generally, intelligence, and the author give him a spur by saying, page 79, that "a workman thus using his intelligence will soon prove a better workman than he was before." The work is well illustrated, most of the illustrations being of actual machines and tools, many of which are the manufacture of the Britannia Company, which has made the construction of lathes a speciality. From our pages last week it will be seen that modified forms of lathes are being designed for winding the armatures of dynamos, and we have no doubt that ere long almost all armatures will be machine wound. Of course, the ordinary lathe is largely used in all shops, and this little book will form a good introduction to the subject, and should be in the hands of all apprentices and

persons who are likely to have such machines under their control.

COCKBURN AND DAY'S SWITCH.

We illustrate herewith a new switch, which has just been designed and made by Messrs. Cockburn and Day. The illustrations almost suffice to explain themselves. Fig. 1

Cockburn and Day's Switch. Serpentine base.

FIG. 1. On. S shows locking spring.

shows the switch on; Fig. 2 shows it off. As will be seen, when full on, the switch is locked by a spring and catch. On turning off, a quarter turn must be first taken with the finger-piece, when a cam forces down the locking spring.

Cockburn and Day's Switch. Serpentine base.

FIG. 2. Off. S shows locking spring.

and immediately this is down, the powerful spring of the switch proper comes into action, and breaks contact so quickly that any chance of sparking is reduced to a minimum.

ELECTRICAL TRACTION.

Electrical traction has made great progress since the first experiments, and, according to the calculations of M. A. Baudouin, of Brussels, in a recent paper before the *Anciens Eleves des Arts et Metiers*, may even now be obtained at

the same cost as horse traction. Still, the weight of accumulators, compared with that of the total load to be drawn, appears too great, and it is towards the reduction of this weight that the efforts of inventors should be directed.

An ordinary tramcar is transformed into an electric car by making the outside panels movable, and raising the body. The accumulators are arranged under the seats, and are divided into several series independent of each other, to facilitate the exigencies of traffic. Each series is placed in a drawer sliding on rollers, connected by automatic contacts with the regulator. Elements of the same series have their electrodes connected by soldering, the outside electrodes terminating in two contacts arranged on the plates of the drawer; and these contacts encounter spring plates, which establish communication between the various portions of the system.

In the Julien accumulators the supports of the plates are unalterable, so that their durability is said to be very great. After long service on the Brussels tramways, they show no alteration of form, and are perfectly rigid. The grids are cast of lead, mercury, and antimony, an alloy which is not oxidizable, and has the property of rendering the plate inalterable. The output of the accumulators is very regular, and they are capable, with a relatively small weight, of storing up a large amount of electric energy.

With two sets of accumulators, one in and one out, the car is in a favourable condition for working. It is thus that the automotive cars of the "Electrique" Company took part in the Antwerp competition, and are now running on the Brussels tramways. They weigh about six tons, including passengers and accumulators, the weight of which but slightly exceeds a ton. Recent trials have shown that a car can make a daily run of 50 kilometres, or 33 miles, with a single set of accumulators, the weight per ton per kilometre, therefore, not quite reaching 5 kilogrammes, or 11lb. The set of accumulators consists of four groups of 30 cells, each weighing 12.5 kilogrammes, or 27.5lb., connected in series, and yielding at the terminals, 60, 120, or 240 volts. The current from the accumulators on the heavy gradients of the lines on which the cars are running does not exceed four or five amps. per kilogramme (2.2lb.), and the tractive effect is put at 12 kilogrammes, or 26lb per ton.

According to the results of experiments made on cars with a carrying capacity of thirty places, on several lines, 4 kilogrammes, or nearly 9lb., of accumulator plates are required for the transport of one ton the distance of one kilometre, or 0.62 mile. This proportion gives a gross weight of 5.5 kilogrammes or 12lb., including the boxes and the acidulated water. In most cases, therefore, this figure is taken as a basis for calculating the weight of accumulators necessary for the transport of a given weight for a known distance.

The weight of accumulators which enters into the total weight to be transported necessarily depends on the efficiency of the apparatus employed, and it remains to be seen whether very light or heavier couples should be preferred.

A good set of accumulators is the essential basis of a rational system of electrical traction, provided it be accompanied by a motor working under favourable conditions, so as to avoid polarization. The use of accumulators lends itself perfectly to the exigencies of service on lines with the steepest gradients. On starting, the current flows in great quantity to the motor, diminishing as the speed of rotation increases. This is just what is required in tramway work. The accumulators permit of regulating this current in proportion to the effort to be exerted.

As has been said, the accumulators are divided into several sets or series independent one of another, there being generally four to a car. These sets are connected with the terminals of a special switch which permits of grouping at will the four sets in parallel, or two to two in series; or the four sets may be connected up in series.

The necessity for frequent recharging is an obvious drawback when automotive cars are used, so that it is advisable to work with as few chargings as possible; and it is towards this desideratum that the working of the Brussels electric cars is tending.

The car which took part in the Antwerp competition weighed 4,250 kilogrammes, or about four tons, and had

1,200 kilogrammes, or rather over a ton of accumulators, with 560 kilogrammes, or 1,234lb. of motor mechanism. The weight of the accumulators was made up as follows:—Plates, 840 kilogrammes = 1,851lb.; liquid, 220 kilogrammes = 485lb., and boxes, 60 kilogrammes = 132lb. In this example the active substances of the plates weighed only 26 per cent. of the whole. They had been specially made for a line with heavy gradients, one of them requiring a tractive effort of 8 h.p. The speed of the car was increased from about three to four metres per second at Antwerp.

In another car exhibited there were 96 accumulators, coupled in series of 12. Each cell, of a capacity of 15 ampere hours per kilogramme, included 17 elements, and weighed about 10 kilogrammes, or 22lb., without liquid or receptacle, the total weight of the battery being about a ton. The eight groups only constituted four series—that is to say, there were never more than 48 elements in series. The motor was combined to work with a current of 20 to 30 amperes. A car on the same system running at Hamburg has 14 places inside. The accumulators consist of 15 plates each, and the battery is composed of 96 cells, the gross weight of which, including water and box, is 1,200 kilogrammes = 23½ cwt. The motive-power is three-quarters of a horse-power per kilometre, or, roughly, 1 h.p. per mile.

In the Julien car the power is proportioned to the load by the regulator, which couples up the required number of cells, and is indispensable to the system. It has the advantage of superseding the artificial resistances used in other systems of electrical traction for regulating the power. One of these regulators is placed on the platform at each end of the car, a loose key for working the switches engaging in a sector provided with teeth, each of which corresponds with a special group of plates.

To change the batteries when exhausted, the car is brought alongside a table or platform, upon which are slid the boxes containing the exhausted accumulators. The car is then pushed forward alongside another table or platform holding the accumulators which have been charged, the terminals pressing against automatic contacts put in communication by leads with the general circuit.

M. Bandschep insists upon the charging station being well and conveniently arranged, as any hesitation or negligence in charging the accumulators leads to considerable loss of time, and he concludes that the future of electrical traction depends in a great measure on the power of the accumulator and a suitable combination of the battery with the motor which it supplies.

PHOTOMETRY.

Captain Abney and Major-General Festing have recently communicated to the Royal Society the results of their experiments on the photometric measurements of the light emitted by glow-lamps. They showed some time ago, that as the temperature of a carbon filament or platinum wire in vacuo was raised in temperature, the rays of light and heat emitted followed a definite law governing their intensity, and that the total radiation, as measured by a thermopile, varied with the number of watts expended, diminished by some constant. They then anticipated that the radiation due to the visible rays increased in a manner which could be graphically represented in the form of a parabolic curve if the abscissa represent the watts expended, and the ordinates the intensity of the light. In order to see whether this conjecture were a true one, an incandescent lamp, through which a fixed current passed, was taken as a standard for comparison. A second similar lamp was subjected to currents of varying strength, and the light emitted by it was determined in terms of the standard lamp by the Rumford, or shadow, and the grease-spot methods of photometry. Each lamp was connected with an amperemeter and a voltmeter, and in front of the standard was placed a pair of sectors, whose aperture could be varied by rotation, and worked by an electromotor. The comparison was effected by two methods—the first consisted in cutting off more or less light from the standard light by

means of the rotating sectors, and the second by varying the current by alteration of the resistance in the circuit of the lamp undergoing comparison. A considerable number of experiments were made on both of these plans, and also by the grease-spot method, which was found to yield very concordant results. A Woodhouse and Rawson lamp and a Swan lamp were examined by these methods, and results were obtained which prove the accuracy of the law which they predicted. Mr. W. H. Preece, from his photometric experiments, came to the conclusion that the intensity of illumination in a glow-lamp was proportional to the sixth power of the current, and from the results obtained by Abney and Festing it is seen that this empirical statement is exact within certain limits. They have also arrived at the same results by a photographic method. The total light, as measured by a photographic plate, was found by them to vary with the watts producing the light in the same parabolic manner as when the total light radiation is measured photometrically. The results by this last method, however, do not show such satisfactory numbers as in the former experiment, owing to the want of uniformity of all parts of a photographic plate and experiment errors in determining the time of exposure and the density of the plate after exposure.

LAMP-HOLDER.

The accompanying illustration shows a simple lamp-

holder, manufactured in considerable numbers by Messrs Woodhouse and Rawson. The illustration explains itself.

ELECTRICAL TRAMWAYS: THE BESSBROOK AND NEWRY TRAMWAY.*

BY EDWARD HOPKINSON, M.A., D.S.C., ASSOC. M. INST. C.E.

(Continued from page 365.)

There are two generating dynamos of the Edison-Hopkinson type, manufactured by Messrs. Mather and Platt, of Manchester. Each is shunt-wound, and intended for a normal output of 250 volts, 72 amperes, at a speed of 1,000 revolutions per minute; but they are never used coupled, as one dynamo is found to be sufficient for the working of the line. Although the average current for a day's work does not exceed 72 amperes, the current required for starting a heavy train on a steep gradient may be three times this amount. It is essential, therefore, that a dynamo intended for such purposes should not only be mechanically strong enough to develop an output far exceeding its normal output, but also that its design should be such that the variation in the lead of the brushes with the current should be as small as possible, and that the fall in electromotive force as the current increases should not be excessive. The latter condition can be met by compound winding, but, on the other hand, the ease with which shunt machines can be coupled parallel is in favour of their use. It

* Paper read before the Institute of Civil Engineers, and reprinted by permission from the *Transactions* of the Institute.

is also of considerable importance to keep the self induction of the main circuit as a whole as low as possible, otherwise the sudden variations in current at stopping or starting of the train is a severe strain on the insulation both of the generator and motor dynamos and on the conductor cables. If the generator dynamo were series-wound, or partially so, the self induction of the circuit would be considerably greater than with a simple shunt-wound generator. Both by reason of the small variation in lead and electromotive force, and also the mechanical strength of the drum form of armature, the dynamos employed are particularly well suited for the purpose, and have given most satisfactory results. The resistance of the field magnets is 7.4 ohms, and of the armature 0.12 ohm, consequently, the electrical efficiency, when working with the normal current, is 92.2 per cent., and the commercial efficiency 90.4 per cent.

CONDUCTOR.

The conductor (Fig. 7) is of channel steel, laid midway between the rails, and carried on wooden insulators nailed to alternate sleepers. The channel form presents several

number, the electrical continuity of the conductor is broken by insulating a section of the channel, and the current is conveyed by a cable laid beneath the sleepers. The top of the channel being level with the rails, the intervening space can be paved or planked, thus making a good roadway without interfering with the mechanical continuity of the conductor. As none of these crossings exceed in width the length of the locomotive cars, the leading collector makes contact on one side the crossing before the back collector breaks on the other. The cables are of stranded copper wire, consisting of thirty-seven No. 14 B. W. G.—1st, cotton lapped and varnished; 2nd, heavily covered with pure rubber; 3rd and 4th, double served with best rubber separator; 5th, covered with pure rubber; 6th and 7th, taped with double-served proof tape, the cable then vulcanised and made water tight; 8th, lapped with thick serving of tarred hemp; 9th, braided overall and heavily compounded.

In constructing a conductor of iron or steel, it is of the utmost importance to specify the composition. Steel may be obtained with a specific resistance, varying from 0.00001 ohm to 0.00007 ohm, according to the amount of carbon,

FIG. 4.

FIG. 5.

obvious advantages. It can be obtained readily in a variety of stock sections without being specially rolled for the purpose. It does not require to be secured, but can be simply laid on the insulators, which fit into the channel and, while allowing longitudinal motion to compensate for changes of temperature, hold it laterally. It is also a most convenient section for making the joints between consecutive lengths. The joints must be sufficiently strong mechanically, and at the same time offer no electrical resistance. Double fish-plates placed externally on either side the webs are sufficient for the first object, but the rust between the surfaces in contact often causes almost complete insulation. The electrical connection is therefore made independently by a strip of soft copper of such section that its conductivity is about the same as the steel. It is bent in a U form to allow for the expansion and contraction of the channel. These strips are riveted in the channel with double copper rivets, care having been taken that the hole in the channel was perfectly free from rust before the riveting. At the several crossings of occupation roads, twelve in

silicon, and particularly manganese.* The steel used was manufactured by the Darlington Steel and Iron Company, and specified not to exceed in carbon 0.15 per cent; silicon, 0.05 per cent; manganese, 1.00 per cent. The actual composition according to the makers' analysis is carbon, 0.09 per cent; silicon, 0.02 per cent; manganese, 0.63 per cent; and the specific resistance 0.0000121 ohm. The weight per foot of the conductor is 4.33 lbs. (6.46 kilograms per metre), and the section 1.367 square inch (8.817 square centimetres). The cost, delivered at the wharf at Newry, was £7 10s. per ton. High conductivity copper could not at that time be bought under £84 per ton, with a specific resistance of 0.0000016 ohm, showing a gain in favour of steel over copper, having regard to weight and conductivity, in the ratio of 3 to 2.

At one point the lines cross a country road obliquely, the crossing being 150ft. in length. The method before described of bridging the gap was here not feasible, and it

* "Magnetization of Iron." By John Hopkinson. Phil. Trans. 1885 vol. 176, p. 463.

was necessary to resort to some other device. A copper wire was slung centrally between the rails from cross-bars carried on posts, placed on each side the rails at either end of the crossing, the lowest part of the catenary being 15ft. above the road level, to meet the requirements of the Board of Trade. An overhead collector, formed of bar iron, fixed above the roof of the car, passes under the cross bar, and immediately makes contact with the wire before the back collector leaves the ground conductor, and continues to make a rubbing contact until the leading collector has again made contact with the ground conductor on the other side the crossing. This method of carrying the conductor and making contact with it was devised in 1885 by the author's brother, Dr. John Hopkinson, and has proved in every way a most complete success. The collector on the roof of the car, though merely a bar of flat iron 1in wide, greased with tallow once a week, makes a perfect contact with the copper wire sufficiently good for transmitting 120 amperes. After an experience of two years there is no perceptible wear on the wire except at the point where it is picked up by the collector, and even here it is very small. An overhead conductor has many advantages over one placed on the ground level or beneath. There is no interference with crossings, it is less subject to malicious or accidental injury; and, particularly, perfect insulation and isolation can be secured, enabling currents of much higher potential to be used with safety. There is no doubt that some animals cannot stand a shock of 300 volts, and it is probable that the Board of Trade would not sanction the use of any higher potential, if there was a possibility of the conductor being accidentally touched. With an overhead conductor there is no such risk, and much higher potentials would be permissible, giving greater economy in the transmission of the power. On the other hand, the difficulty of making contact with an overhead conductor has hitherto opposed almost insuperable difficulties, now obviated by this simple device. In the crossing above referred to, two catenaries are used with the points of support at different levels, in order to reduce the tension of the wire and the pull on the posts, which, in this instance, is not balanced by a like pull on the opposite side, as would be the case were the conductor constructed throughout on this principle. The wires are of hard, drawn copper, No. 4 B.W.G., and the actual tension is 120lb. The inclination of the catenaries to the horizontal is $\tan^{-1} \frac{1}{4}$, and the collector clears the underside of the cross-bar by 5 $\frac{1}{2}$ in., and therefore picks up the conductor at a distance of 6 $\frac{1}{2}$ in. from the posts.

The insulators upon which the channel steel is supported are blocks of poplar wood 5in long. These are carefully dried, and then impregnated with boiling paraffin. A block of dried poplar will absorb as much as 75 per cent. of its own weight of paraffin, which permeates through the whole mass. These blocks have proved efficient insulators, and are apparently standing well. The actual measured insulation of the conductor, under unfavourable circumstances as regards weather, and when charged to a potential of 250 volts, is about 900 to 1,000 ohms per mile, approximately the same as the author obtained at Portrush.* Such an insulation is sufficient for practical purposes. It represents a loss through leakage of $\frac{1}{4}$ ampere, or one-tenth of a horse-power per mile. The actual measured leakage current of the whole line in wet weather amounts to nearly four times the above amount, the excess being probably due to some slight fault in the cables and arrangements at the points and crossings.

The circuit is completed by the rails of the permanent-way, which are uninsulated. As is the case with the conductor, the fishplate connections are not sufficient, and are supplemented by flexible copper strips riveted to the under surface of the rails. The specific resistance of the steel rails (Barrow Hematite) is 0.000166 ohm, and hence the total resistance of the four rails, having an aggregate area of 12.4 square inches, is 0.033 ohm per mile. The resistance of the conductor is 0.221, making the resistance of the circuit 0.254 ohm per mile. Allowing for the

earth and for some contact resistance, probably 0.25 ohm per mile fairly represents the average resistance (0.156 ohm per kilometre). The electrical connection of the rails of the permanent way is essential, since the earth connection is of little value, as the rails are practically insulated by the sleepers and dry ballast. A curious confirmation of this occurred during a severe thunderstorm. At the first flash, a man employed at the Newry end of the line, who was touching the rails, but not the conductor, and standing on wet ground, received a smart shock, and simultaneously with the lightning flash the attendant observed a blaze of light from the earth-brush of the generating dynamo. At the second flash a similar discharge was observed at the brushes, and at the third flash, more intense than the others, the same occurred again, and the fusible plug connecting the conductor with the dynamo gave way, and two men engaged at the Hessbrook end of the line and touching the rails, but not the conductor, received severe shocks. Clearly, in each case the system, as a whole, had been struck, and the charge was making the best of its way to the earth. After this occurrence the precaution was taken of connecting the rails of the permanent-way to the earth at several points.

(To be continued.)

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

CENTRAL STATION LIGHTING—TRANSFORMERS V. ACCUMULATORS.

BY P. L. CROMPTON, REMERE.

Mr. Crompton at the end of his paper (given in our last issue), stated that he hoped the members would give him credit for having endeavoured to be absolutely fair to the two systems. He had given everything to the A.T. system that he could give it, and for the B.T. system he had taken figures which he was quite prepared to adopt in practice, and, in fact, they were based upon practical experience. He denied the statement as to his being a recent convert to accumulators, as he was the first in England to mention Faraday's discovery in which he had great hopes. He used accumulators largely at the Law Courts, but got tired of them, as they did not work satisfactorily. They had, however, been much improved, and were in a better condition for electric lighting than for any other work they were called on to do. In unskilled hands accumulators were difficult to manage. He had 1,350 E.P.S. cells to work at Vienna, which were of the older types, but worked satisfactorily. He strongly impressed upon the meeting that accumulators could at the present moment do the work remarkably well with an extremely small loss.

Mr. Gilbert Kapp thought that the makers of accumulators could not have found a better advocate for their system than Mr. Crompton. Accumulators were originally planned for the Victoria Institution, but they were never fixed, probably on account of their unavailability. He was glad, though somewhat surprised to hear that they were now reliable. In his remarks he might have referred from him, but he much admired the plucky way in which Mr. Crompton had fought the battle of accumulators against transformers. He had made an impression upon Mr. Kapp's mind, and he was still open to conviction when he saw the calculations offered by Mr. Crompton to substantiate his words. He did not consider a maximum output of 3,600 watts per day too much for a plant which could supply 600 kilowatts at the lamps, and the reason why the London diagram exhibited by Mr. Crompton was lower than those for Boston and Cincinnati was no doubt due to the supply to theatres and public halls being low. He agreed with Mr. Crompton that there was something more than the price of copper to be taken into account when speaking of the cost of a mile of cable. But Mr. Crompton had erred in assuming 1 per cent. were in excess of the price at which cables could be purchased. A twin main would cost £130 for 100 yards, whereas Mr. Crompton had taken £137. If an insulated cable could be placed directly in the ground with a plank covering to warn workmen that it was under the road, the cost of laying would not be more than 3s. a yard, so that with £10 for surface boxes the total cost would be £155 for 100 yards against £137.

Mr. R. E. Crompton said his figures were those found to be incurred by actual experience.

Mr. Gilbert Kapp: The insulation of the oil-covered cable could be measured by megohms, while that provided by Mr. Crompton would only be a few hundred ohms or a thousand ohms per mile. An Edison cable, for the Edison Company, gave 500 megohms per mile, and others laid for the Thomson-Houston plant there gave 1,200 to 1,500 megohms before being laid, and 350 megohms when laid and struck. Another Edison cable in Milan, having two conductors, was laid in June 1885, and continued to work to the present day with one or two interruptions, which was due to an experiment with alternating currents. He would rather not be the engineer responsible for knocking up the insulation of naked conductors, especially when a loss of 5 per cent. on Mr. Crompton's estimate could be effected by using the Barthou-Hess cable. In his distribution the plan he advocated was to use high-tension cables for the feeder and low-tension cables for the network of supply. He did not pretend

* Mr. Holroyd Smith, with an underground conductor, found the leakage current to vary from 30 to 100 amperes, with an electrostatic force of 220 volts, showing an insulation resistance of 4.4 to 13.2 ohms per mile.

ELECTRIC LIGHTING ACT.

At a recent meeting of the electrical trade, held at the offices of the Anglo-American Brush Electric Light Corporation, Limited, it was decided to petition in favour of Lord Thurlow's Bill now before the House of Lords to amend the Electric Lighting Act of 1882, and the following petition has been extensively signed by the principal electrical companies and firms, and by gentlemen representing the scientific interests of the industry:

In the House of Lords, Session 1888.

ELECTRIC LIGHTING ACT (1882) AMENDMENT BILL.

PETITION IN FAVOUR OF THE BILL.

To the Right Honorable the Lords Spiritual and Temporal in Parliament assembled.

The most humble petition of the companies and persons being traders and persons interested commercially and scientifically in the subject of electric lighting in the United Kingdom, whose seals and names are herewith attached and subscribed.

1. A Bill is now pending in your Lordships' House intitled "An Act to amend the Electric Lighting Act, 1882," and having for its especial purpose the extension from 21 to 42 years of the period limited by the aforesaid Act of 1882 after the expiration of which, local authorities may have an option of purchasing electric lighting undertakings within their district, and being in respect of the aforesaid extension of time based upon the report from the Select Committee of your Lordships' House on various Electric Lighting Bills in the year 1886.

2. Your petitioners claim to represent the commercial and scientific interests of the United Kingdom on the subject of electric lighting, and are of opinion that the proposed extension of the aforesaid period, and other amendments of existing law proposed by the said Bill, will so far lessen the restrictions which have hitherto prevented this industry from developing as to enable at least some progress to be made in its development.

3. Another Bill has been introduced into, and is now pending in your Lordships' House, intitled "An Act to Amend the Electric Lighting Act, 1882," and bearing the short title of "Electric Lighting Act, 1882, Amendment No. 2 Bill," the object of which is to effect far-reaching changes in the existing law, which, while they might very possibly attain the object in view, raise weighty and complex questions connected with the powers of local authorities, and your petitioners are very apprehensive that the discussion of these questions must necessarily lead to further delay in affording relief of which the public, desirous of having the advantage of electric lighting, and the electric lighting industry is so urgently in need. Your petitioners therefore respectfully submit that the Electric Lighting Act, 1882 Amendment Bill lately heretofore referred to, which is based as aforesaid upon an exhaustive inquiry which has already been held, ought not to be delayed pending any inquiry which may be considered necessary into the proposals contained in the Electric Lighting Act, 1882, Amendment No. 2) Bill, and that if the proceeding with the last named Bill would have this effect, it should not be proceeded with.

Your petitioners therefore most humbly pray your Lordships that the Electric Lighting Act, 1882, Amendment Bill may be allowed to pass into a law in the course of the present session, and that the Electric Lighting Act, 1882, Amendment No. 2) Bill may not, so far as its proceeding will delay the passing into law of the previous Bill, be allowed to proceed.

And your petitioners will ever pray.

PARLIAMENTARY INTELLIGENCE.

ELECTRIC LIGHTING ACT (1882) AMENDMENT (No. 2) BILL.

In the House of Lords on Tuesday last,

The **Earl of Crawford**, on rising to move the second reading of this Bill, remarked that he did not intend to weary their lordships by going into the former discussions upon this subject, and that the Bill was rather more extended than any previous measure relating to electric lighting. He would, however, briefly explain the changes which he proposed to introduce into the law on this subject. Under the second clause of the Bill the persons who were known as undertakers, and who provided currents of electricity for the purpose of distribution to individuals within a certain area, would be permitted to make their arrangements with the local authority as a licensing authority without having to go to the enormous delay and expense of going to a central office for a provisional order, and of having that order subsequently embodied in a special Act of Parliament. The cost of the provisional order system and the Parliamentary procedure consequent thereupon was undoubtedly very high, and, in addition to that, there was the grave objection that that course of action could only be taken during a certain portion of the year. Unless everything was not foreseen for the next six months, no work practically could be proceeded with until a new provisional order was obtained. We had to go now into a very much larger question than was contemplated in 1882, when this Act became law. In addition to the method of procedure by license, provisional order, or special Act, the present Bill would enable the local authority to enter into an agreement with, and to grant permission to, the undertakers for their several works and purposes as set forth in this Bill. In the event of the local authority refusing, the Board of Trade would be authorized to step in and to say whether that refusal was a just and a right one or not. Clause 3 went into the question of the description of the supply, and proposed that it should be given only under certain rules to be laid down by the Board of Trade. The application of elec-

tricity for lighting purposes had been in use for six or seven years, and in consequence of the demand the Phoenix Insurance Company started in 1882 a printed set of rules for the guidance of persons who were using the electric light. By carefully following those rules accidents might, as far as possible, be avoided. The rules were first published in the *Times* in May, 1882. He had made it his business to inquire whether there was any additional risk placed upon buildings which were lighted by electricity or in which the electric light was employed. He was informed by the Phoenix Office that no extra premium was charged on buildings prepared for the reception of electricity under the rules they had drawn up, even though other modes of lighting were also used. In regard to the question of safety for life, he was informed by the Phoenix Office that where a building was wired in accordance with the rules laid down by the fire insurance offices, they considered that there was no greater danger to life than there would be in an ordinary dwelling house. Therefore he said that the Board of Trade, in framing any rules for the guidance of undertakers, ought to give great weight to the rules which had already obtained during so many years, and which were drawn up by those who were thoroughly acquainted with the subject. Clauses 4, 5, 6, and 7 of the Bill were practically taken from the Gas Act of 1847, which was incorporated in the Electric Lighting Act of 1882 as far as those clauses were concerned. Those clauses contained all that was necessary in regard to the powers to be given to undertakers in taking up streets in passing from one part of a town to another. Clause 7 gave the local authority the power in all cases to do the work of breaking up the streets and reinstating them. Clause 10 was intended to give a legal status to telephones, which were now doing such valuable service, and to protect them from all possible damage by an electric lighting undertaking. He also proposed that when the undertakers were not the local authority, but a company or private individuals, they should pay a certain sum per annum to the relief of the rates for the privilege of being allowed to use the streets. He would suggest that the sum so to be paid should be £20 a mile, and in Committee of his Bill should go into Committee. He should be prepared to state the amount which that rate would realise if London were properly dealt with. The lords would be surprised to learn to what extent the rates of London would be relieved if this were done. The Act of 1882 presented the periods within which the works of an electric lighting undertaking were to be finished. He would propose to leave that question to be settled between the local authority and the undertaking. The next thing was that within five years from the passing of the Act, all cables, or wires, or mains for electricity should be placed underground. Clauses 16 to 23 he had adopted from the Gas Act of 1871, and they regulated for the instruction of inspectors the methods of testing and the supply of the current to the consumer. Clauses 24 to 27 were necessarily of a temporary character, as they related to the character and quality of the supply which at present there was no instrument accurately to test. He hoped to be able to work out in the laboratory a means of "standardizing" the measurement and the current. Clauses 38 to 44 dealt with measurements, and he hoped to induce the Government to make a small addition to the Weights and Measures Act for the purpose of putting technical meters on the same footing as gas meters. In dealing with the supply to be furnished to the general public, he had followed the lines of the Gas Act, 1871 so that every householder within 25 yards of the distributing main should have a right to a current of electricity, and the undertakers should be under similar obligations to those of gas companies. He had also given the undertakers, subject to certain conditions, the power of withdrawing the supply on account of the use of a dangerous or objectionable lamp. Clause 32, also following the Gas Act, gave a local authority power to require a supply if they were within 50 yards of a current. Clause 33 dealt with the question of penalties. He did not desire to invest the electric lighting companies with any permanent monopolies, all that he asked was that they should be placed in no worse position than they were in when they first entered into their contracts. He hoped that the Bill would now be read a second time, that a great industry which had been kept back for six years, since the Act of 1882 was passed, would have room to exercise their capital. He knew of his own knowledge that if the law were made somewhat on the lines of this Bill, that in the course of six or eight months large sums of money would be thrown into the country, and employment provided for large numbers of working men. He believed that 40,000 men would speedily be employed in preparing these works and upon the business of electric lighting. In conclusion, he would only add that, in preparing this Bill, he had kept himself entirely free from any bias in favour of the electric companies, and he had endeavoured to take a fair view of what was due to the local authorities and the gas companies. He had, in fact, tried not to be a partisan one way or the other, and he trusted that this Bill, the second reading of which he begged to move, would meet with the approval of their lordships as being fair and equitable. (Cheers.)

Lord Thurlow said, while agreeing with much which had fallen from the noble earl, he did not find himself in a position to withdraw his Bill on this subject. It was only a large amendment in the existing law which would set the large amount of capital ready for investment free. Ever since the Act of 1882 firms and companies of electric engineers and others interested in the subject had petitioned Parliament for such modifications in that Act as would remove those restrictions, which, it was alleged, had the effect of crippling the progress of electric lighting, and in a petition which was presented to their lordships' House yesterday those gentlemen had expressed a view, which he shared, that a Bill so complex in its character as that of the noble earl stood but a faint chance of finding acceptance, if not in this House, at any rate in the other House of Parliament. Having regard to the circumstances and the subject matter, he had no hesitation in saying that the petition embodying that view was signed by a representative and influential body of names as could be brought together. The second reason why he was unable to withdraw his Bill in favour of that of the noble earl was that it was too soon after the great Act of 1882

the whole question. All that was wanted was a simple measure to the companies giving them a larger measure of time in to recoup themselves for their original outlay, so that they should be compelled against their will to charge their clients a prohibitive price for the electricity which they supplied. A measure of such proportions, dealing with public questions so complicated and important, moreover, to be brought in on the advice of the Board of Trade, another Government department, in order to do complete justice to the interests at stake. His third objection was that it legislated by means of detail which should be left to be dealt with by local order according to the measurements and requirements of each locality. Lastly, with regard to the purchase clauses, he objected to the fact that it did not recognise the absolute right which the local authority should have, in his opinion, to become the purchaser on fair terms of undertaking of a private company supply of electric light within a local authority.

Earl of Onslow said the speech of the noble marquis on the second reading of his noble friend's Bill would have that the Government were sincerely desirous to do what they could to promote the extension of electric lighting, and if it had been that the Bill now before them had represented the feeling of the Government in promoting electric lighting in this country, it had deserved a more attentive consideration; but, as had been pointed out, a petition had been laid upon the table, signed by a number of leading firms in the trade who would be most likely to be negotiated with the local authorities, and that they were in favour of the Bill of the noble lord opposite, Lord Thurlow.

He further said that since the Government consented to the second reading of the Bill of his noble friend opposite, there had been a very large number of applications to the Board of Trade in the hope of the extension of time from 21 to 42 years would have the effect of bringing capitalists to embark money in these undertakings. This proposal to make an important change in the existing law, so Parliament had declined to allow companies promoted, whether for the purpose of electric lighting, gas supply, or tramways, to make bargains for themselves without the supervision and consent of Parliament. But this Bill proposed to abolish the provisional order system, and the noble lord only proposed to do it in the case of the electric lighting companies. There were, he admitted, proposals in which were commendable. No doubt it would be a great step to secure, within a reasonable period, that those overhead wires which were a danger and disfigurement to the metropolis should be underground. In the Bill of the noble earl there was no provision for any penalty upon any company which failed to carry out the laying of wires. Again, hitherto it had been a practice that the city or individuals liable to repair certain streets within the area of the undertaking which were not repaired by the local authorities, the able to appear before the Board of Trade and state their case as well as the promoters, and those streets were then placed under the order. As he understood the Bill of the noble earl, persons would not under it have the opportunity of appearing before any authority, and would have to submit their case to arbitration. The principle which Parliament had always enunciated was, that a monopoly should be set up; they had had sufficient experience of the result of creating a monopoly in gas, water, and other matters. The Bill it was stated that nobody should have any permanent monopoly, but from the word "permanent," he gathered that there was a temporary monopoly—i.e., while the order ran, and the noble earl had omitted to state any time for the duration of the order. With regard to the clause which proposed to give local authorities the power to purchase, he thought that it would have been better to set that question in a more direct manner. With regard to the manner in which an undertaking was to be acquired by the local authority, hitherto Parliament had laid down the principle that the company which sold might be a public company, with the value of which was quoted on the Stock Exchange, and the price would be readily ascertained, but if it were a question of a private company or an individual, there would be no such means of ascertaining the value. Again, there were many companies which were engaged in electric lighting as a part only of their business; in that case it was obviously difficult to separate the value of the electric light from that of the other business. This Bill proposed to confer a new power on the local authorities. It should be remembered that these authorities were undergoing a very great change, and it was very doubtful whether it would be wise to confer upon them powers such as these; in his opinion, the local county councils might very reasonably be jealous of these powers being conferred upon smaller authorities. It was possible to discuss in committee of the whole House all the legal and technical proposals of this Bill. Although it was true that many committees had sat to consider this question of electric lighting, still they had not dealt with all the technical and difficult points set out in this Bill. As he had said before, the Government desired to do all that they could to encourage the investment of money in electric lighting, and although he had stated several grave objections to the Bill of the noble earl he did not wish to throw any obstacle in the way of the increase of electric lighting. He therefore, that this Bill might be allowed to go through its second reading and then he would suggest to the noble earl that it be referred to a Select Committee, and that on the report of that Committee the next stage of the Bill should be taken.

Marshall was glad to hear that the noble earl who had just spoken did not intend to oppose the second reading of the Bill now

before them, because it involved questions of considerable interest and importance; and if some alteration were made in it, it would not be inconsistent with the passing of the other Bill dealing with the subject, which had received its second reading. He would regret extremely, however, if this Bill were made a ground for postponing the progress of the Bill to which he had referred, because the Bill of the noble earl no doubt raised very complicated questions which would mean minute discussion and examination, and he was anxious lest the effect would be to hang up this question to an indefinite period and prevent any legislation on the subject passing at any early date. With regard to the petitions which had been referred to, he believed that they were directed towards supporting the scheme which was already in progress rather than to opposing the Bill of the noble earl. There was no doubt that the Act of 1882, with regard to the terms of purchase, needed amendment. It was not the case that whether the terms were onerous or not was a matter affecting only the promoters and the local authority; apart from the question of whether they could make the terms such as to induce capitalists to put money into electric lighting, he thought that the public had a distinct interest in seeing that the terms were not too onerous, as the undertakers would seek to recoup themselves by charging more than they otherwise need for the electric light. That meant that the present generation was to pay more than they otherwise need for the electric light in order that the next generation might get it for less than they ought. He hoped, therefore, that the measure of his noble friend, which had already been read a second time, would be allowed to proceed. At the same time, he hoped that the Bill of the noble earl would be read a second time. Owing to its complicated character, he thought there was little chance of its passing through the House this session.

The Bill was then read a second time.

COMPANIES' MEETINGS.

MONTEVIDEANO AND BRAZILIAN TELEGRAPH COMPANY.

The ordinary general meeting of the Montevideo and Brazilian Telegraph Company, Limited, was held on Monday at the office, Tokenhouse buildings, Moorgate street, Dr. Cameron, M.P., in the chair.

The report of the Directors for the year ended December 31 stated that the percentage of gross revenue receivable from the Western and Brazilian Telegraph Company had been £2,508, as compared with £2,370 in 1886. They were glad to observe that, so far as could be judged from the published returns from the Western and Brazilian Companies, there appeared some prospect of a greater improvement in the traffic during the current year. The debentures issued in 1876 were made redeemable on the 1st July, 1896. There being a balance of £10,280 still unrepaid, it would be necessary to set aside annually a larger sum for the purpose of redemption than hitherto, and they therefore proposed to appropriate £1,000 for that purpose for the year 1887. Out of the balance of £474 they recommended a dividend of 1s. per share on the preference shares, leaving £58 to be carried forward. Mr. James Joyce, M.P., had been elected a director to fill the vacancy caused by the death of Sir T. Gore Browne.

On the motion of the Chairman, seconded by Lieutenant-Colonel G. W. Macaulay, the report was adopted.

COMPANIES' REPORTS.

THE "PILSEN," "JOEL," AND GENERAL ELECTRIC LIGHTING COMPANY, LIMITED.

Report of the Committee of Investigation appointed by resolution of shareholders at an extraordinary general meeting, held on the 13th March, 1888, to investigate the statements contained in the Directors' notice, dated 3rd March, 1888, convening such meeting, and to confer with the Directors, and to report thereon, and generally upon the business of the Company.

The statement in the Directors' notice, dated 3rd March, 1888, that the amount of the working capital of the Company amounts to but £7,093, is taken from the last report and balance-sheet, issued on the 10th November, 1887. This sum of £7,093 is made up in such balance-sheet of the items of:

Cash including £2,986 6s. Consols,	£3,037 9 0
Stock, plant, stores, &c.	3,874 0 11
and the difference between	
Debtors to the Company	£966 3 11
and Creditors of the Company	784 13 5

181 10 6

£7,093 0 5

As to the above item of cash, this has practically disappeared, as the whole of the Consols have been sold out, and the proceeds expended by the Directors, and the cash at the bankers at the commencement of this investigation was the sum of £140. 17s. 6d. only. As to the item of stock valued at £3,874. 0s. 11d., this is the Directors' estimate of the value of the whole of the stock, plant, and stores, &c., of the Company. As the three installations of the Company alone, at which a part only of such stock, plant, stores, &c., are employed, were earning, as stated in the last balance-sheet, a yearly rent of £3,485. 0s. 6d., and are now stated to be producing a gross yearly income to the Company of £5,000, it has been considered necessary to check this estimate of £3,874. 0s. 11d. by taking stock of the whole of the existing stock, plant, stores, &c., of the Company, and this has been very carefully

done, with the following results, which it has appeared convenient to classify as under—

	Producing per annum.	Original cost to Company.	Directors' valuation.	Present valuation.
Stock, &c., at Bethnal Green Installation—	£1,200 0 0	£2,158 10 11	£416 14 7	£1,482 5 7
Stock, &c., at Whitstone Park Installation—	£1,556 0 0	£4,564 0 0	£900 18 0	£4,500 0 0
Directors' estimate of additions since June, 1887—		£2,328 5 11		
Stock, &c., at Stanhope-street Installation—	£1,156 13 4	£2,116 14 3	£1,193 19 0	£1,819 1 9
Stock, Plant, Stores, &c., at Stanhope-street Factory—		£5,413 19 6	£1,022 0 0	£2,093 9 0
Stock at Agents and on Hire—			£340 9 1	£340 9 1
	£3,914 13 4	£12,653 4 8	£6,802 6 7	£10,235 5 5

There has been great difficulty in arriving at the above figures in consequence of the unsatisfactory mode in which the books of the Company have been kept. There has been no stock ledger and no store ledger kept since 1884. There has been no stock book kept since 1884 except that the stock list of 1887 has been copied into a book. But the stock lists and valuations, it is stated by the Secretary, have been kept separately for each of the years 1884, 1885, and 1886, and he states that such stock lists and valuations for the years 1884 and 1885 cannot be found, and they have not been produced. It has therefore not been possible to trace or account for the stock from the year 1884, which in the balance-sheet of that year was then valued by the Directors at the aggregate sum of £29,876, 8s. 4d. It is presumed that the shareholders do not desire to have in this report the details which are very intricate and elaborate, and can be supplied if desired, but only the results of the investigation; and in obtaining the results which are here presented to them every care has been given to make all due allowances for wear and tear and other circumstances of depreciation. Having regard to all such considerations, the value of the now-existing stock, plant, stores, &c., of the Company is believed to be the above sum of £10,235, 5s. 5d. In examining the valuation of such stock made by the Directors, it has been found that the stock, &c., has been most seriously under valued. For example—a large number of Pilsen arc lamps in perfect order and in full working at installations, and each earning £20 yearly and upwards for the Company, figure in the Directors' valuation for 8s. 9d. each. The price list for such lamps is £12 each. The glass globes cost 10s. each. If sold by auction, these lamps realise from £5 to £7 each and the mere value of the metal, if broken up and sold as scrap, is 8s. 2d. The sum of £3,874 0s. 11d. held by the Directors as the value of the stock, was arrived at by valuation in June, 1887, and there has been since that date certain additions to such stock, but Consols have been sold out by the Directors in the years 1887 & 8, which have realised £4,769, 7s. 5d. In conference with the Directors as to the mode in which this sum has been disposed of, the only explanation given was that it had been spent upon the business of the Company as would appear by the balance-sheet to June, 1887, and by the cash book. To enable the shareholders to determine how far this explanation is satisfactory, it has been considered necessary to prepare an analysis of the cash-book, and in order that the years in which such a sum of Consols was expended may be compared by them with the years in which no Consols have been expended, the analysis has been carried back to the year 1884, and accompanies this report. The analysis is strictly compiled from the Company's cash-book, and the attention of the shareholders should be directed, amongst other things, to the fact that, although the income received by the Company from "sales of plant, &c.," has enormously decreased, the outgoings for "rent, rates, and taxes, purchases of stock, &c.," and "wages" have varied but little comparatively. Also that in one year £1,092, 11s. 1d. was expended in law costs, while the largest dividend paid in any year is £821, 18s. 8d. Also that a sum of £2,500 appears in the cash-book as a loan to "Ellis and Co.," and in conference with the Directors this is explained by them as having been lent to these gentlemen by the Directors with the object of obtaining 3 or 4 per cent. interest from them. This lending of the money of the Company by the Directors to individuals appears to be wholly irregular and unauthorised by the articles of association, and, moreover, upon investigation by the Committee, it is found that it was lent at an interest of 1½ per cent. per annum only. There also appears an item of "contract for running new main Holborn, £195, 19s. 4d.," and this was found upon investigation to be a payment to another firm of electrical engineers to run electrical wires to the Company's installations. This would seem to be peculiarly work proper to be done by the Company's own workmen instead of employing another firm to do it at a profit. In conference with the Directors, then explanation of this matter was that they thought it would be advisable, and was the best course in their opinion. As to the statement in the Directors' notice that the item of £25,190 for goodwill and patent rights should be no longer maintained at that figure, and their intention of reducing it to £527, in conference with the Directors, the following were the reasons given by them for this proposed reduction—That the patents stood at cost price, and had only seven years to run, and that they were advised that if they earned profits it would not be advisable to pay dividends upon that amount. There was no data furnished for the reduction to £527, which appears to have been a purely arbitrary sum, and is given by the Directors as their opinion of value without supplying any basis of its calculation. In proposing this enormous reduction, as a matter of principle, and apart altogether from the amount of it, the Directors have merely considered the fact that the patents are running out, and have entirely ignored the goodwill, overlooking that under good management the value of the goodwill of the business should increase at least the amount of the diminution of the value of the patents. It is obvious

that the mere goodwill of a business which is said to earn £5,000 per annum from its installations must be worth immensely more than £527. As to the general business of the Company, under the existing system of management it has not been, and it is not possible that it should be, worked with either efficiency or economy. There is no proper system of check or control of stores issued. The books of the Company are not properly kept, and some of them are even now not posted since January last. The Company have obtained many orders for lighting and have left them unexecuted for several months, in some cases actually going to the expense of running the wires without having any lamps. There is no reserve of power at the Stanhope-street Installation for any further business, and at Whitstone Park Installation there is no reserve boiler power, and the whole installation is at the risk of a leak from the leakage of a single tube. The sum of £4,769, 7s. 5d. has been realised from the sale of Consols by the Directors, and spent by them during the period in which two of the three Directors were disqualified, and their office vacant without any improvement in the financial position of the Company, and lost for the repayment by them since the last meeting of £200, which they had improperly paid themselves for directors' fees, the Company would have had absolutely no money at the bank at the commencement of this investigation. In the now existing condition of the Company it is, of course, necessary that capital should be obtained to enable it to carry on its business properly or at all. The business, if properly managed, should be a successful and profitable one, as the system of lighting is exceedingly popular with all its customers, the number of whom might be almost indefinitely increased. It is suggested that it has not been possible to submit this report to the shareholders at an earlier date, but the committee have not been facilitated by the Directors or the Secretary in their investigation, and from the 29th March to the 4th April instant the offices of the Company were closed, the Secretary absent, and the books locked up although he had been distinctly informed that the committee wished to have access to them, and continue the investigation during that period. During that absence of the Secretary and Manager one of the installations had to discontinue its lighting of a public house at 9.30 in the evening because at the Stanhope-street Factory there were no coals. The attitude of the Directors in regard to the investigation will appear from the following letters.

68, Cornwall gardens, Queen's Gate, S.W., March, 1888.

Dear Sir, I have been expecting to hear from the committee appointed at the "Pilsen" meeting on the 15th instant to confer with my late colleagues, but hitherto I have received no communication from them. Mr. Treatham informs me that you wish to take stock. At present I do not see the utility of this, or that it comes within the scope of the resolution, but, of course, I shall be glad to hear what the committee has to say on this subject.

For this or other purposes it seems to be in accordance with the resolution that there should be a meeting of the committee viz. myself and my late colleagues, and upon hearing from you I will either convene such a meeting myself, or will endeavour to arrange to meet the committee with my colleagues.

I do not read the wishes of the shareholders, as expressed by the resolution, to be that you or the committee should take any action at the factory, or at any of the installations, except in conference with me.

I take the opportunity of informing you that the intervention of the Easter holidays, and the convenience of the shareholders, seem to me to make it desirable to hold the meeting to elect Directors on the same day as the adjourned meeting (13th April). Notices will be shortly issued accordingly.

Please communicate this letter to the committee.—Yours faithfully,

(Signed) RAWSON W. RAWSON.

Chairman of the Pilsen-Joel and General Electric Lighting Company, Limited.

St. Stephen's-chambers, Telegraph-street, E.C.
27th March, 1888.

"PILSEN" AND "JOEL" COMPANY.

Dear Sir—I beg to acknowledge the receipt of your letter and 23rd, but delivered on the 25th inst.

Neither I nor my colleagues on the committee whom I have been able to consult can accept your view as to the very limited scope of the investigation which you suggest, but, of course, when we are in a position to do so usefully by means of the investigation we are making we shall wish for an opportunity of conferring with yourself and the late Directors, and will ask you to be so good as to arrange it. I do not but think it was a strong proceeding to delay the meeting for election of Directors, when the Secretary had been directed by the shareholders to send out notices forthwith.—Yours faithfully,

(Signed)

JAMES FAY.

Sir Rawson W. Rawson, K.J.M.C., &c.

EASTERN EXTENSION TELEGRAPH COMPANY.

The report of the Eastern Extension, Australasia, and China Telegraph Company, Limited, for the half year ended December 31 states that the gross receipts inclusive of Government subsidies amounted to £252,660, against £216,856. The working and other expenses, including £22,730 for cost of repairs to cables and expenses of interest on debentures and contributions to sinking funds, and brought forward £235,162, there is an available balance of £153,608. A quarterly interim dividend of 1½ per cent. has been paid and it is proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year, a total dividend of 4½ per cent. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. to 1887. The balance of £53,051 has been carried to the general reserve fund, which

The number of Directors shall not be less than three nor more than seven. The first shall be appointed by the subscribers to the memorandum of association. The qualification of a Director shall be the holding of stock or shares in the capital of the Company of the nominal value of £250 each. The remuneration of Directors shall be the sum of £800 per annum, paid out of the funds of the Company, and divided amongst them as they may think fit.

St. James' and Pall Mall Electric Light Company. This Company has been formed in order to establish a central station for the supply of the electric light to the area of which St. James' square may be described as a centre, and which includes Pall Mall, St. James's-street, Piccadilly and Waterloo-place. The prospectus has been advertised during the week, but the lists close before the issue of the technical papers. The prospectus states that a provisional contract has been made with Messrs. Latimer Clark, Matheson, and Co., of Westminster for a supply of the necessary plant to establish a first installation of 10,000 lamps, in full working order and with every requisite, at an estimated cost of £18,500 to be erected in portions as required by the Company. The price and the terms of the contract are to be subject to the approval of the Engineer of the Company. The price of the site is £9,500, and a rent-charge of £100 a year for forty-two years. The charge for lights will be made either by contract, at a certain sum per lamp per annum, or by meters, which will be tested and

certified by professional authorities. The Company will pay nothing for patents, and will pay its own preliminary expenses, which will be the charges actually incurred. The people who have formed the Company and guaranteed the preliminary expenses and the subscription of a portion of the capital, look for their remuneration to the 100 founders shares of £1 each, which will be taken up by them. The capital is £100,000 in 19,900 ordinary shares of £5 each, and 100 founders' shares of £1 each, and 10,000 of the ordinary shares are now offered for subscription, of which it is stated 3,000 are subscribed by the Directors and their friends. The district it is proposed to light is perhaps one of the best in London for such a purpose, though it should not be forgotten that many of the large hotels, clubs, and houses in the district are already provided with the electric light.

Southampton Electric Light and Power Company, Limited. Registered by Richard Jordan, 120, Chancery-lane, W.C. Capital £30,000, divided into 4,000 preferred shares of £5 each, and 2,000 ordinary shares of £5 each. Object: To carry on the business of electricians, mechanical engineers and manufacturers, and workers and dealers in electricity, motive power and light, and generally any business in which the application of electricity, or any like power, is, or may be, useful, convenient or ornamental, or any other business of a like nature, to carry on the business of manufacturers of, and dealers in, machines, lamps, lanterns, safety lamps, and other appliances for supplying light and power by means of electricity. The first subscribers are—

Name.	Shares.
J. H. Abldridge, M.D., 13, Anglessea-place, Southampton	2
J. Bishop, beer manufacturer, Grosvenor-square, Southampton	1
E. G. Rose, brewer, Westwood, Southampton	1
J. Appleford, merchant, Millbrook, Southampton	1
J. G. C. E. Vaneor, Lloyd's agent, Southampton	1
J. Miller, outfitter, 177, High-street, Southampton	1
E. Brown, butcher, 17, Above-bar, Southampton	1
R. Allen, 183, High-street, Southampton	1

There shall not be less than three, nor more than twelve Directors. The first shall be appointed by the subscribers to the memorandum of association. The qualification of a Director shall be the holding of his own right of shares of the nominal value of at least £250. The remuneration to the Directors shall be fixed by the Company in general meeting.

of nickel slowly increases with the temperature from Odeg. to 225deg. cent., and more rapidly from the latter temperature up to 365. From this point the resistance augments more slowly as the temperature is increased. 2 That the temperatures at which the variation in the rate of the increase of resistance occurs are the same as those at which irregularities in the thermo electric properties of the metal are observed.

The Electric Light in Sweden.—The experimental installations carried out at Stockholm have been so successful that the same system that of Messrs. Ganz and Co., of Budapest will probably be adopted in a large number of new installations. The machines already working in this capital are located at the gas works, and the total length of the distributing mains is 2,000 metres. The conducting wire is of copper, 4 millimetres in diameter, and is supported on posts. Several restaurants are lighted by incandescence lamps, and the entrance to the opera by several arc lights. The town of Falun is shortly to be lighted by 50 arc lamps of 1,200 c.p., and 300 incandescence lamps.

Arc Carbons.—The manufacture of carbons for arc lighting has in Austria become an industry of some importance. The Hardtmuth factory, at Döbling, produces about 3,500 metres of carbon rod per diem. The processes of manufacture have recently been improved in several particulars, the carbons being of greater density and more homogeneous. The improvements apply more particularly to cored carbons. The rod, formed of plastic material, passes from the press in the usual manner in the form of a tube. After drying and baking, the carbon tubes are saturated with a hydro-carbon, which fills the pores; and after a second baking the core material is introduced at a certain pressure.

A "New" Lamp Maker. A well-known electrician told us a pretty good story the other day, the truth of which he vouches for. He, in company with another gentleman, was recently visiting a place where dynamos were manufactured. The superintendent, who was also, we believe, the electrician of the establishment, showed them through the factory, explaining the principle of the machine made by his company, and talking on various electrical subjects. In the course of the conversation Mr. Superintendent was asked whose lamp they were using. He replied he was not quite sure on that point, but (examining the lamp) thought it must be Mr. Volt's, as his name was on the lamp.

Electricity Ubiquitous.—The Electric Club of New York is replete with every electrical appliance. Thus, on approaching the door, instead of using a bell-pull, the visitor, by pressing his foot on a metal plate, rings an electric bell, and the door is unlocked by electricity and opens at once. The house is lighted by incandescent lamps, of which there are 350. In the kitchen is an electric gridiron, which broils the meat by use of electricity from the lighting apparatus passing through and heating the wires of the gridiron. The boots are blacked and polished with brushes worked by the same power, the clocks wound, the lock on the safe opened, and even the piano played by electricity.

The Installation at Saint-Etienne.—Quite recently unexpected difficulties have arisen in connection with the working of the rental station in this town, a description of which was given in our last issue. It is stated that in those portions of the distributing system where copper bars

enclosed in iron tubes, filled with an insulating compound, are employed, a large number of lamps can no longer be worked, and it has been necessary to have recourse to gas. It is evident that the insulation between the direct and return mains has broken down. According to the *Bulletin International de Electrotechnique*, the Saint Etienne Company intend to take proceedings against the Edison Continental Company, under whose advice the system of laying which has occasioned the breakdown was adopted.

The Bell Telephone Case.—The *Electrical World* says: As to the generally prevailing impression that there is more or less probability of a rehearing of the Bell telephone cases by the United States Supreme Court, Justice Miller says that such action is extremely improbable. In the twenty five years he has been on the Supreme Bench there have been but ten rehearings. When, as in the telephone case, the bench is nearly equally divided, every point bearing on the case in the most remote degree is thoroughly canvassed, and nothing in any way bearing on the case is passed over. But when the bench is unanimous, or nearly so, a decision may perhaps be reached without so thorough a canvass of all phases of the subject, and some minor point may be overlooked and a rehearing granted, but this is a very rare circumstance.

Monkeys on Telegraph Wires. A formidable antagonist to telegraph construction in Mexico is found in the monkey tribe which inhabits the jungles and chaparral of Tabasco. Literally "the woods are full of them." Their favourite diversion when not in quest of food is to betake themselves to the telegraph lines for gymnastic exercises, and linemen assert that often 100 able-bodied monkeys have been seen swinging on the wire, festooned, monkey fashion, by looping their tails. The continuous vibrations of these forest gymnasts start the iron nail used on the cross arms, and these often come down, bringing the wire with them. And it is not a safe matter to undertake to disperse these robust monkeys, who play the dickens with telegraph lines in the sparsely inhabited State of Tabasco. Linemen have found that on shooting a monkey swinging on the wire they have been pursued by a whole regiment of monkeys.

The Writing Telegraph.—In the House of Commons on Monday Mr. McEwan asked the Postmaster-General whether it was true that, after six months' consideration, the Post Office authorities had refused to grant a license to the proprietors of the Writing Telegraph to use their system under the same conditions as the various telephone companies use their systems; and whether, if it be true, this was in accordance with the usage in respect to other companies desiring to use telegraph systems. Sir H. Maxwell: I am requested by my right hon. friend to say, in reply to the hon. member, that it is the fact that, after due consideration, he has refused to grant a license to the proprietors of the Writing Telegraph. He thinks it preferable that, if there is a substantial demand for the establishment of exchanges to be worked by that instrument, they should be in the hands of the Post Office, the instruments being supplied by the proprietors on terms to be arranged.

St. James'.—At a meeting of the St. James' Vestry, last week, Mr. John Bonthron presiding, it was agreed to support the application of the St. James and Pall Mall Electric Lighting Company to the Board of Trade for a licence. The draft licence follows the lines of the South Metropolitan Electric Lighting order, but

of the theatre in front of the stage are lighted by 180 20-c.p. lamps; whilst the stage is supplied with 1,162 lamps, of which 550 are in ordinary use, and 612, tinted with various colours, serve to obtain different effects of light. The lighting and the regulation of all these lamps are controlled by a commutator of special make. About 630 cut-outs are distributed in the circuits so as to obviate any accident.

Commission of Sewers. Last week a special meeting of the Commission of Sewers was held at the Guildhall to consider a letter from the Remembrancer relative to the application of the South Metropolitan Electric Light Company to the Board of Trade for a provisional order. Mr. W. H. Pannell presided, and said the Remembrancer would read a letter from the Parliamentary agents to the South Metropolitan Electric Light Company, enclosing copy of a letter from the Board of Trade stating that it was proposed to consider objections to the license at 11 o'clock on Friday, when the representatives of the Commission of Sewers were requested to attend. The chairman said that on the last occasion a resolution was passed by the Commission instructing the Remembrancer to lodge objections to several Bills in Parliament, this being one. The Remembrancer did lodge objections accordingly. The area laid down by the company included part of the area called Blackfriars site, with regard to which the Commissioners were at the time in negotiation with the Brush Company. This was one of the choicest sites in the whole metropolis for electric light, comprising all the newspaper offices. Since then the Commission had declined to go further with the Brush contract; therefore, an important factor in their application was removed. They had already four applications before the Commission or its committees from four electric lighting companies, with offers to light the whole or a portion of the City.

The Central Station at Rome.—Important extensions of electric lighting are taking place in this city. Amongst the most recent installations carried out by the Gas Company are those at the Quirinal piazza, the Quirino Theatre, the Metastasio Theatre, the Cafe des Varietes, and the establishments of Messrs. Bocconi and Messrs. Pinzi and Bianchelli. The piazza above mentioned, the lighting of which has given great satisfaction, contains nine arc lamps of 1,000 c.p., worked by transformers located at one of the angles of the palace of the Council, and connected to the central station by Siemens' cables. The lighting of the Quirino Theatre comprises one exterior arc lamp and 200 incandescence lamps in the interior of the building. That of the Bocconi establishment includes one central arc lamp of 2,000 candles, 86 arc lamps of 1,000 candles, and 200 16-c.p. Edison incandescent lamps. The latter are included in a special circuit, worked by an Edison dynamo located in the basement, and driven by an Otto gas engine. The arc lamps are arranged in ten distinct circuits, corresponding to the same number of transformers, worked from the central station. This installation has produced a great effect, being much admired by the public. No description of meter or counter is used by the company, the consumption being paid for according to the number of lamp-hours, which is noted, and jointly verified by the company and the consumer. This system will no doubt be found very disadvantageous when a number of small consumers have to be supplied; but it would appear that a simple and cheap meter, giving accurate indications which can be read by the consumer himself, is a desideratum which is not yet forthcoming.

Gas Companies and Electric Lighting.—In America, the gas companies are closely watching the progress of the electric light, and from time to time, at meetings, papers are read the moral being that it will be well if the gas companies take up the work themselves. The men interested in the gas interests there are much more open to conviction than men similarly situated here, to judge from the technical journals. We are fairly consistent readers of the *Journal of Gas Lighting*, for example, and for a long time past this paper has devoted one article per week to the consideration of electric lighting. The humours of *Punch* are not in it when compared with the humours of these articles. Pope, the greatest exponent of poetic satire and rancour, would have paled before the prose writer of the *Journal*. Nothing good can possibly come out of electricity hence, week by week, we are amused at the extraordinary efforts made to find out some weak spot. The writer quotes largely from the *Electrical Review*; but is so utterly unable to understand the meaning of what he quotes, that his lucubrations, instead of convincing, end simply in being amusing. The same paper, however, occasionally has the courage to quote from American contemporaries, as for example, in its issue of April 24, when it gives a paper by Mr. Day, read at the annual meeting of the Ohio Gas-Light Association. The conclusion of this paper is as follows:—"It would seem from the figures here given that gas companies are much more favourably situated for furnishing both arc and incandescence lights, or electric currents, than anybody else, and that they should pursue the policy of fortifying themselves in their present positions by obtaining authority to do so if necessary. Keep an eye on the public pulse, and if they will have it, give it them. By so doing they would make a powerful ally of what might, under some circumstances, be a formidable foe. Failure to occupy a field of action in advance of others sometimes results in disaster. Are not these words of wisdom to our own gas companies?"

Anglos.—The following letter to the *Financial News* shows that there is a growing dissatisfaction with the directorship of the "Mutual III Society." We have strong reasons to believe that the directors will not forego one ounce of their pound of flesh, nor one stiver of their fees. A director may with advantage to himself be a director in a dozen companies, but we doubt if it is so advantageous to the shareholders:—"The Anglo-American Telegraph Company is again paying a fractional dividend, while the shares are drooping in value, and nothing is heard of peace negotiations between the rival companies. Some months ago you most conclusively pointed out in your paper the advantages that would follow on a settlement of the cable war, and the restoration of a fair and just scale of rates, and with your able advocacy I still hope to see the object attained. It is admitted on all hands that the sixpence rate is too low to admit of anything more than the ghost of a profit on the amount of capital invested, while a fifteen or twenty pence rate would be fairly remunerative to the shareholders, would not be considered exorbitant by the public, and would be far below the rate charged a few years ago. Then, why should this insane and unbusinesslike competition and war of rates continue? Six months ago the Commercial Company were willing to make the rate twenty pence a word if the other companies would follow suit, but no agreement was come to. If the directors of the Anglo Company, in keeping to the sixpence rate, are inspired by a feeling of universal benevolence and philanthropy, then they

should put themselves into the same boat with the shareholders, and abjure their fees; but if they wish to make their company a financial success, while at the same time conferring a benefit on mankind, they should renounce their policy of masterly (1) inactivity, and endeavour strenuously to effect an equitable adjustment of rates. Should they fail in this, after honest and straightforward attempts at reconciliation, then the shareholders will know where to lay the blame; but from the previous action of the Commercial Company it is evident that a twenty pence rate would be willingly agreed to by them."

Non-Magnetic Watches.—Our American cousins know how to advertise, and are not afraid of the returns from the amount thus expended being unsatisfactory. The Waltham Watch Company is of a different calibre to the Waterbury Company, and both companies do a large business in England. Why should this be? No doubt the answer is that English firms take years to consider the advisability of providing what is required, while the Americans try to anticipate the requirements. Viewing some installations the other evening, a friend said, "Look out for your watch. Mine won't hurt it is a special Waltham." The reply was, "Neither will mine, for I haven't one." An article in the *Scientific American*, of April 14th, on this subject contains the following sentences:—"People carrying valuable watches, or depending upon pocket timepieces of any kind, seldom properly appreciate the risks they run of destroying their accuracy and rendering them totally unreliable by going anywhere near electrical machinery, of which the use is now becoming so general. From this one cause probably proceeds more of the 'crookedness' in the watches now made than can be attributed to any other one source, and it is a difficulty which watch makers have been earnestly striving to meet by the use of anti magnetic shields, composition balance wheels, &c. What seems to have been a successful effort in this direction, by the American Waltham Watch Company, was recently made the subject of an interesting test. The company, after a long series of experiments, has perfected an alloy for use in their balance wheel, escapement, and hair-spring, which is apparently non-magnetisable, and not affected by proximity to the strongest dynamos. One of their regular watches, provided with these parts made of this alloy, was subjected for fifteen minutes to the influence of Major King's great cannon magnet at Willetts Point, N.Y., without at all affecting the time of the watch. The watch was held in close proximity to the muzzle of one of the guns, forming one pole of the magnet, where the magnetic effect was strongest. Its mainspring and other portions became so highly charged as to retain their magnetism for several days afterwards; but the hair-spring, balance, and escapement were so totally unaffected, that the rate of the watch, as noted by an astronomical clock before, during, and after the experiment, showed no change whatever. The use of dynamos is now becoming so general that one never knows when he may be in close proximity to one, either in travelling on the cars, visiting places of amusement, inspecting goods in stores or warehouse, or in manufacturing establishments of any kind. Their influence is not interfered with by the interposition of walls or partitions, and the hitherto trusted timepiece needs but to be brought sufficiently near to be rendered worthless, or have its value seriously impaired, while the owner may be in total ignorance of the cause. The result now obtained by the Waltham

Company is said to be secured without any sacrifice of the qualities desired in the parts of the watch made of their improved alloy, the latter itself being slightly different in the different parts."

Organ-Blowing by Electricity.—A new departure has been made at St. John's Church, Taunton, where the first successful attempt has been made to solve the problem of organ-blowing by electricity. The organ has 36 stops, and the blowing is so quietly effected—without the vibration which even the steadiest manual blowing imparts, and without the tension on the bellows which blowing by gas engine involves—that the pleasure of playing upon so excellent an instrument is greatly enhanced. The organist has at any time of the day or night simply to take his seat at the manuals, and turning on a switch—as he would turn on a water-tap can commence playing at once. This switch brings the whole arrangement under his complete control; it is affixed to the front of the organ just above the stops on the right hand of the manuals, and communicates through a series of carbons which bring the current to a very low intensity, and render the appliances perfectly safe to handle—with the motor in the tower some 45ft. above. The motor is of nominally half-horse power, but will develop about double that power. It weighs 42lb., and occupies about ten square inches of space: the armatures change the polarity of the electro-magnets surrounding them, and thus cause the revolutions of a wheel about 3in. in diameter—about 1,600 revolutions per minute being attainable. The motor, which is by Messrs. Immisch, was supplied, and the electric connections made, by the Electric Lighting Company, under the superintendence of the electrician-in-charge, Mr. Hooker, and it is worked by 30 large-sized accumulators at the central depot, rather more than a quarter of a mile distant. The motor and machinery attached thereto are suspended on beams built into the tower, so as to avoid the possibility of any vibration. The small wheel of the motor is attached by a half-inch rope to a fly-wheel 4ft. in diameter, an ingenious arrangement by a weighted pulley compensating for changes in the temperature. This portion of the work has been carried out by Messrs. Allen, engineers, Taunton, and the remainder by Mr. Minns, organ builder. The fly-wheel operates a double feeder, 4ft. by 2ft., which, when working at full speed, will make 90 strokes and deliver about a million cubic inches of air per minute. Close by is a reservoir, with powerful concussion bellows, and this communicates, by means of a trunk 40ft. long, and 22in. by 5in., with the large wind chest of the organ; this trunk is carefully insulated and ends in a small chamber with a roller valve, acting automatically, which prevents too great a pressure of wind being forced into the wind chest. As soon as the wind chest is full, the current is broken by an automatic switch and the motor stops; but when the reservoir has lost about an inch of its distension, the switch again completes the current and a few revolutions of the motor restore the equilibrium—a piece of asbestos preserves the woodwork from injury by the flash arising from the breaking of the current. The organist is provided with two switches, one of which is of low intensity and allows a sufficient current for ordinary service playing, while the second supplies the additional power necessary in case of a prolonged loud voluntary. On the whole the installation is a most gratifying success, and Taunton may be congratulated on leading the way to another application of the uses of electricity.

THE USE OF ELECTRICITY FOR THEATRE LIGHTING.*

BY R. GEORGE TIDD.

Before entering upon the subject of the various systems and their working now in use in our London theatres (for I shall confine myself exclusively to London), I wish to point out the great advantages which accrue, both to the public and to the management, both to those before and behind the curtain, by the use of electric light in theatres.

Firstly, then, the danger of fire would be *must be* very materially decreased by the use of the electric light.

Almost all our great theatre fires, of which we have heard of so many lately, have had their origin behind the curtain, in the "flies," where the fearfully inflammable material of which the scenery is composed is ever in close proximity to, comparatively speaking, unprotected gas jets, and which, perhaps, by the merest chance, a puff of wind, or a slight flaw in the working of the scenic machinery, may catch some portion of the canvas, thickly coated with oil and paint, and in the short space of a few minutes the whole building may be in flames. Now, were these fatal gas-jets replaced by electric lamps, what matter if the wind, or an accident in the machinery, or any other unforeseen cause bring them in close contact with the scenery—there would be no risk of fire. When one thinks of the frightful calamity which only a few months ago happened at Exeter, by the burning of the theatre in that town, caused by just such an accident in the flies, of the awful loss of life which attended it, and under the most horrible and distressing circumstances, one cannot help feeling that those who have the safe keeping of the theatre-going public in their hands are wanting in their duty by not ordering the compulsory use of electric light in all theatres, by which they would enjoy almost a complete immunity from fire, and I am glad to hear it reported that the new Metropolitan Theatre Bill will contain a clause making the use of the electric light compulsory in our theatres.

It is interesting to note that while those in authority have caused hundreds of pounds to be spent to insure the safe exit of an audience in case of fire, they have not yet taken any steps whereby the chances of that event might be lessened. It is, of course, a very wise thing to take precautions in case of fire, but would it not be much better to take precautions against the risk of the fire itself? By compelling managers to use the electric light, and that light only, behind the curtain in their theatres, the chances of fire would be reduced almost to a minimum.

Another great boon which the electric light confers upon the public, and which adds materially to its comfort, is the absence of that excessive heat which is always felt in any building where a quantity of gas is burnt; again, the nauseating smell caused by stale burnt-out gas is entirely absent. Undoubtedly, to a great extent, the heat in theatres—and there must always be heat where a quantity of people are massed together—is caused by the want, and in some cases, I believe, by the almost entire absence of proper ventilation. Of course, it is a difficult matter to ventilate a theatre to perfection, but is not this all the more reason for having electric light, by which the imperfect system of ventilation would not be so much felt? Go to the Criterion Theatre, for instance—which, bear in mind, is totally underground, being under the restaurant, and the roof of the theatre being on about a level with the road—and there, by a fair system of ventilation, combined with the use of the electric light and entire absence of gas, the performance is carried on in an atmosphere of purity and, as compared with other theatres, of coolness, to the comfort of all concerned.

Some have adduced the argument that the illusionary effects produced by gas and limelight would be unobtainable with the electric light. This is quite a mistake; several managers to whom I have spoken say that they much prefer the electric light, and we must surely agree with them when we see it adopted at the Gaiety, where, perhaps, more than at any other theatre, these effects are required. In fact, I believe that far greater effects could be obtained

by the use of the electric light, for whereas gas can only be *turned down low*, the electric light can be completely extinguished at will, and can be as instantly relit, without the least trouble. *Appropos* of this subject, an objection that managers advanced, and that some still put forward, against the electric light, is that it cannot be partially raised and lowered at will; this, as you all know, is quite an erroneous idea. And while on the subject of objections of managers, we may just give a word as to the arguments of the cost of electric lighting. Now, for instance, the Alhambra has just been redecorated at a cost of £10,000, and this outlay will last three times as long as it would have done under the old system of gas, thereby fully compensating for the original outlay on the electric light installation.

The Lighting of a Theatre by Electricity varies in several important points from an ordinary installation, and there are special details which require careful consideration. First, to take the requirements of the auditorium. The lamps in the passages, cloak-rooms, &c., are always required to be alight, so they must be on a separate circuit to themselves. The light in the auditorium itself is required down during the performance, and up between the acts. In some theatres all the lights are *lowered*, and in others most are entirely extinguished, while a few are left at full candle-power. This, of course, requires the lamps to be on two circuits.

Here I will point out a precaution that I think should always be taken—namely, having in the auditorium two complete circuits, so that in case of a breakdown or fault in one circuit the theatre will not be plunged into darkness, and there would be no risk of panic. To lower the light all we have to do is to lower the difference of potential between the terminals of the lamp. This is done practically in two ways: (1) by inserting a resistance in the circuit; (2) where accumulators form part of the circuit, by cutting out a certain number. In the first case a certain amount of energy is always being used, only a part of which is doing useful work, the other part being employed in overcoming the resistance. In the second case, only the amount of energy which is expended in useful work is drawn from the cells; an objection to this is that the cells are discharged unequally, so that in fully charging the cells with the least charge a certain amount of energy will be wasted in over-charging the more fully-charged cells. By joining up the various circuits to the cells according to their use, position, &c., the discharge can be rendered more uniform. Another great objection to this method is that when the number of cells in circuit is altered, either the circuit is broken or the additional cells are short-circuited. I believe Profs. Ayrton and Perry have devised a switch to obviate this by putting a cell on to a resistance.

To work on a strictly efficient basis, it would be more economical, when half the light is required, to switch off half the lamps, as the efficiency is much higher if the lamps are running at a high candle power. Thinking that perhaps it might be of interest to some here, I plotted a curve of candle-power and efficiency with tests made with a nominal 20 candle power lamp. In speaking of the efficiency, I mean the inverse of the true efficiency. If I took the true efficiency or candle power per watt, the result would be a fractional quantity. You see from the curve that the efficiency keeps very low until 5 or 6 candle-power is reached.

Now to consider the most important part of a theatre installation—viz., the stage lighting. The principal lights used are as follows:

(1) *Floods or Footlights*.—Generally two rows for white and green lamps, and where great effects are required a row of red lamps is added. These three sets are generally all put in the same circuit with simply make and break switches.

(2) *Proscenium Lights*.—Two sets of these are required, one on either side of the proscenium; they are often on hinged boards, so as to turn to any angle.

(3) *Battens or Top Lights*. There are never less than three rows of battens, and generally more. Each row must be able to be separately regulated.

(4) *Wing Ladders or Side Lights*.—There are two or more

* Paper read at the Students' Meeting of the Society of Telegraph-Engineers on Friday, April 20th.

pairs of these, but they are never permanent fixtures. They generally hang on rods from the roof, so as to be readily brought forward or backward, and turned to any angle. Special connections are required on account of their often having to be entirely removed.

All the lights on the stage must be arranged for raising and lowering; whether they are raised and lowered all together, or each set separately, depends upon the theatre and the style of play produced there.

There are now in London ten theatres and music halls where the electric light is used, viz. Alhambra, Criterion, Empire, Gaiety, Haymarket, Oxford, Pavilion, Prince of Wales's, Savoy, Terry's, and one other, viz., Adelphi, where the light is now being installed. There are three new theatres now being built in London, all of which are to be entirely lighted by the electric light; and it is a fact worthy of note that since 1881 no theatre has been built (with the exception of the Avenue) in which the electric light has not been used.

I now propose to give a short outline of the various installations which I have been permitted to inspect. First, I shall take the Criterion Theatre, which is, I think, one of the most satisfactory I have seen, being an installation complete in itself, having the electrical power under its own control, and not being dependent upon loads from any other source. The installation was put up by the Edison Company at the beginning of 1884, and has continued running from that time without a single hitch of any kind. No gas is used in the theatre at all. The plant consists of three old type Edison machines driven by 100 h.p. engine; the engine house, which is a little distance from the theatre, also contains two Edison-Hopkinson machines, driven by a similar engine, and used for lighting the restaurant. The dynamos are connected in arc, being attached to a special plug switch-board. Arrangements are made so that in the event of the engine breaking down all the load would be thrown on to the restaurant machinery. This would, of course, bring all the lamps down, but there are enough that could be switched out in the restaurant by switches in the dynamo room to enable the performance at the theatre to proceed without interruption. The engineer has to keep the difference of potential up to 150 volts. A regulating switch-board is placed in one of the passages leading off the stage. There are ten circuits, which include resistances, which are adjusted by sliding contacts. The first circuit supplies the foot lights (of which there are two rows, a white and a green), of 28 16 c.p. lamps per row. Each circuit has its own switch and cut-out, but both are regulated by the same resistance. The second circuit supplies the dome, where there are 59 10-c.p. lamps. The next supplies the lamps round the circles in the auditorium. The next supplies the wing ladders, of which there are four sets, having a total of 80 lamps. The other six circuits supply the battens, each batten having a separate resistance, so that it can be regulated apart from the others. There are forty 16 c.p. lamps in each. There are, besides these, two more circuits regulated by the two switches at the end of the diagram, one of which supplies the dressing rooms, passages, &c., and the other supplies some lamps which are placed inside reflectors, let into the ceiling of the galleries, so as to give a downward light on to the programmes: these lamps are left at full candle power all through the performance. Each circuit is supplied with a pilot lamp and cut-out. There are about 700 lamps in the whole installation. The resistances are under the stage in a large slate case, which is well ventilated. All the leads, &c., are attached to the back of the switch-board, there being a narrow passage behind it to effect this. The wing ladders have flexible wires attached to them, which are passed through holes in the stage, and fastened to terminals underneath.

I will now take Terry's Theatre, which is one of the most recent ones. The fittings and wiring were done by Messrs. Verity, of Regent street. The current is supplied from the Grosvenor Gallery. At first the supply was anything but regular, but it has lately been better. I shall not renew the question of direct *v.* alternating currents, but shall let facts speak for themselves. This theatre is supplied with gas, which is always kept at a blue flame. There are two Ferranti converters, which are placed in a fireproof place near the roof. The switch-board is placed on one side of

the stage, and consists of ten switches and fuses. The switches marked "front," "dressing rooms," "auditorium," and "wings" worked straight through the lamps; the other six work through adjustable resistances. The resistances are contained in a box measuring only about 18 in. by 12 in. by 8 in., and it is placed on one side of the switch board: each set consists of twelve carbon rods, the tops and bottoms being alternately connected by brass strips. Along the top row of strips a brass slide works, so as to include 2, 4, 6, 8, 10, or 12 of the carbon rods in circuit. With all twelve of them in circuit there is a barely visible glow in the lamps.

The total number of lamps is about 400, and they are distributed as follows: 30 8-c.p. lamps in a circle round the dome. There are no lamps round the various tiers, all being placed at the back. There are nine round the pit, thirteen round the dress circle, eight round the upper boxes, and sixteen round the gallery. The lamps on the stage are as follows:—Flats 21 16-c.p. lamps, two rows battens of 30 each, one row battens of 22 lamps, two proscenium lights of eight each, and 96 lamps distributed over the wing ladders. In all the passages a lampholder and gas bracket are combined. The connections for the wing ladders consist of a plug fitting between two contacts, which are fixed to a slate base, the latter being fastened to one of the beams under the stage.

I will next take the Oxford Music Hall, which is fitted up very similarly to Terry's, having been done by Messrs. Verity, and the current being supplied from the Grosvenor Gallery. The installation has only just had its trial run, so is hardly in proper working order yet. The wiring has all been done in a very perfect manner, and I should think is as near the fire office regulations as possible. Every bracket has a cut-out on each side of it. The switch board is placed just off the stage, and consists of 12 switches, and in the centre a circular slide for the resistance. All the stage lights take up 7 of the switches, and they all work through the same resistance, so that they can only be raised and lowered together. One of the remaining switches is for the dressing rooms, two for the side bars, and the other two for the auditorium, one controls 24 hanging brackets of 3 lamps each, which are switched right off during the performance, and the other controls 6 brackets of 3 each, which are always left full on. There are four battens of 30 8-c.p. lamps each, two proscenium lights of 10 each, and six wing lights of 10 each. These latter are connected by means of plugs, in a similar manner to those at Terry's, only the slate bases to which the contacts are fixed are placed in an iron box filled with cement. The footlights contain 50 lamps, which are connected to bare wires laid in grooved slate, and covered up with Berry's fireproof cement. The slate is laid on an ironwork frame, and insulated from it by means of sheet indiarubber. The whole installation contains 530 lamps. The transformer house is in the basement; the current enters at 2,400 volts and leaves at 100 volts.

Now take the Gaiety Theatre, to which I have before referred. There is a complete installation there, consisting of a 16-h.p. compound engine driving two Goolden Trotter dynamos, but as the plant is placed under the auditorium, where the vibration is felt, it is only used in case of a breakdown at the Grosvenor, from whence the current is obtained to light the theatre. Steam is always kept up during the evening, and during the late burlesque the current was used during the last act to run sixteen 500-c.p. incandescent lamps. The transformer room contains three transformers, two 250-light 100 volt, and one 150 light 50 volt, connected to this distributing switch board. This consists of four double pole switches and cut-outs, which supply stage No. 1, stage No. 2, auditorium, 50 volt circuit. All the switches are arranged with a double set of contacts, so that the lamps can be instantly switched from the transformers on to the dynamos. At the prompt side of the stage there is another switch-board with five sets of sliding contacts, by which resistance is inserted separately into the four batten circuits of 52 lamps each, and the flat of 54 lamps. The total number of lamps in the theatre is 450. The installation was fitted up by Messrs. E. S. Berry and Co., and is still under their management.

Another installation, the stage of which was fitted up by the same firm, is on much the same lines as the foregoing, this

is the Empire Theatre. The current is obtained from the Grosvenor Gallery, although there is a complete set of Elwell-Parker plant there, which had to be stopped on account of complaints about the noise. There are 12 sets of wing ladders, each containing 15 lamps, one set of floats containing 65 lamps, two proscenium lights, each containing 25 lamps, and six battens of 40 lamps each. All the lamps are governed from a switch-board of the same type as the Gaiety. There are 536 lamps on the stage, and about 500 in the auditorium, making a total of 1,036 lamps. The noticeable thing about this installation is the artistic way in which the lamps are arranged in the auditorium. In front of the gallery there are 18 brackets of two lamps each, hanging over the second circle there are 18 brackets of three lamps each, in front of this there are six brackets of four lamps each, and between them are placed five brackets, each containing three gas burners, which are kept alight. In front of the dress circle there is a close row of single lamps. The dome contains eighteen lamps, besides gas jets.

Now, to take the Savoy Theatre, which, if taken in order of perfection, ought to rank first, as it was not only the first to be lit, but it contains more lamps than any other theatre. The installation was first used on 10th October, 1881, and was put up and is still under the charge of Messrs. Siemens Brothers, having worked since the beginning thoroughly satisfactory. The stage is lighted by 715 lamps, and there are 601 blue ones, which are used in the night scene of "Pinafore." The lamps are nearly all on a shunt-wound dynamo, and they are regulated by inserting resistance in the field magnets, a very much more efficient arrangement than that generally employed, the disadvantage being that all the lamps on the dynamo are simultaneously lowered. The battens are made entirely of incombustible material. The wing ladders terminate in triple plugs, which are inserted into contact pieces on the stage. The auditorium is lighted by three branch brackets arranged round the tiers, containing, in all, 150 lamps, the corridors, &c., having 165, and the dressing-rooms 148. The total number of lamps is 1,178, and, with the 601 blue ones, 1,779. The lamps are arranged in parallel on three circuits, one of which is in parallel with a circuit containing two arc lamps, which are used outside the theatre; these take 40 amperes. The plant consists of three Siemens' dynamos of the S.B. type, each giving 400 amperes at 93 volts. The dynamos are driven at 700 revolutions by two Marshall portable and one Robey semi-portable engine, each of 20 h.p. The switch-board is placed in a corner of the stage. The lamps in the auditorium are lowered by inserting resistance in the external circuit, there being other lamps on the same circuit. Some other groups of lamps, which have to be raised and lowered separately, are done in the same way. The raising and lowering is effected by means of four eight-way switches. The wiring is done in such a manner as to minimise the risk of fire, the leads nowhere crossing and being kept a considerable distance apart. There are safety fuses in each branch main, but no double pole fuses are used, but each main lead from the engine room is supplied with a fuse. There are pilot lamps in the engine-room to each circuit. No gas is used in this theatre behind the curtain.

The other theatres are only partially lit on the stage. The Prince of Wales' Theatre has a set of plant, consisting of a 12 h.p. Clark gas engine, but, having one of their new back covers, it gives 16 h.p., a Siemens' D1 dynamo, and 108 E.P.S. cells of the 31 L type, of which three 59 plate cells have been in four years. Lately leads from the Grosvenor Gallery have been brought into the theatre, and the current is obtained from there, the plant now being used only in case of a Grosvenor break-down. The float contains 54 lamps, and there is one batten of 16 lamps. The front of the house, offices, &c., contain 346 lamps; they are all 100 volts and 16 c.p. There are two 150 light converters. The total number of lamps is 416.

The Alhambra has just had the electric light installed in the auditorium, and a little on the stage. The plant consists of two Crossley 9 h.p. gas engines, driving two Edison 150 light dynamos. There are 108 Elwell Parker accumulators, 56 of which are used to light the balcony, and the other 52 are used in parallel with the two dynamos. The only lights on the stage are the floats, containing 80

lamps, and one batten containing 80, this being only used in the last scene of the ballet "Enchantment." The whole installation contains about 300 lamps, the only gas in the auditorium being in the dome.

The Haymarket is supplied from the Grosvenor, but no lights are used on the stage with the exception of a temporary festoon used in one act of "The Pompadour." The installation contains about 120 lamps in the auditorium, and two arc lamps used outside the theatre.

The last place viz., the Pavilion Music Hall—has no electric light at all on the stage, but there are about 300 lamps distributed over the auditorium. The plant consists of two 16 h.p. Otto gas-engines and two Edison Hopkinson dynamos, and a few accumulators for the sake of regulation.

Taking a summary of the various theatres and music-halls, we find that six obtain current from the Grosvenor, and five have their own plant. Out of the six Grosvenor installations, four of them keep gas burning, while the other two have private plant.

In the foregoing remarks I have endeavoured, as far as my ability would allow, to bring before you the present state of electric lighting in our London theatres; and, in conclusion, I would remark that the successful lighting of our theatres and public places by electricity may be looked upon as the forerunner of the universal application and use of this light, wherever practicable, in our houses, and more particularly in the mansions of our nobility, &c., where there is a wealth of paintings and historical portraits, documents, &c., for so surely as the efficiency and comfort is seen and felt in our places of public amusement, so surely will it follow and be enjoyed in the homes of our people. In fact, as it has been said, "Nowadays nothing can be done without advertising," we may look upon the theatre-lighting as a huge advertisement of the electrical profession generally.

THE GRIFFIN GAS ENGINE.

The following is the report on tests of a "Griffin" patent double-acting horizontal gas engine, of Messrs. Dick, Kerr and Co., by Prof. Andrew Jamieson, M.I.C.E., F.R.S. Edin. &c.:

Gentlemen,—I have now the pleasure of reporting to you on the results of my examination and tests of your 8 h.p. Nominal "Griffin" Patent Gas Engine, as made at your Britannia Engineering Works, Kilmarnock. My tests extended over four hours on November 25th, four hours on November 26th, 1887, and over one hour on January 27th, 1888. The engine illustrated on page 396, in its general style and behaviour more closely resembles that of an ordinary double-acting steam engine than any other gas engine with which I am acquainted, for both ends of the cylinder are closed in, and an impulse is given to the piston every one and a-half revolutions i.e., combustion takes place at each end of the cylinder alternately every three revolutions of the crank shaft, when the engine is working under normal conditions. This feature naturally causes the speed of the gas engine to be more constant than single-acting gas engines, and therefore better adapted for driving dynamos or other machinery where constant speed is required. The governing and ignition of the combustible mixture (gas and air) are effected in a manner similar to most gas engines—the former by entirely cutting off the gas supply, and the latter by plain slides. The charging and exhaust valves are of the lifting type. They are actuated by a simple and neat arrangement of cams on a side shaft, which is driven by worm gear from the crank-shaft.

The engine has been specially well designed with a view of transmitting the working stresses to the foundation, and thus avoiding as far as possible any annoyance from vibrations and racking. Great care has been taken to make all the working parts strong and simple, while the workmanship and finish throughout seem to me all that could be desired. Throughout the whole of my electrical test the engine worked very steadily; in fact, I have never before tested a gas engine which maintained such uniformity of speed at full power, no pulsation or blinking being

observable in the incandescent lamps. The mechanical efficiency or ratio of brake horse-power to indicated horse-power, as shown by the following results, is equal to 78.7 per cent., thus proving that but a comparatively small proportion of the whole power developed is absorbed in working the engine itself. The engine is very powerful for the so-called "nominal" horse-power (a term still common among gas engine makers): in fact, it develops very nearly double the nominal horse-power on the "brake." The absolute and the practical efficiencies or ratios of indicated horse-power, and of brake horse-power to gas consumed in terms of heat units (as demonstrated in the appendix), are respectively equal to 19.2 per cent. and 15.1 per cent.; which results are better than I have obtained from any other gas engine.

The following tests were mainly directed to two objects,

6. A water supply tank, fixed a short distance from and a few feet above the cylinder of the engine, with a regulating cock close to the same, was used to give any desired flow of water through the cylinder jacket. The quantity of water passed through the cylinder jacket was reckoned by careful measurements of the fall of water in the tank every five minutes.

7. The brake used was of the form shown by the sketch below, and one was placed on each fly-wheel. It consists merely of a strap and blocks, with the dead weight on the one side, and a spring balance attached to the floor on the other. The load on each wheel, as well as the several dimensions, were as nearly as possible the same. The mean reading of the spring balance, plus part of the weight of the spring balance, was deducted from the dead weight, to arrive at the net brake load on each wheel.

Diagram—Griffin Gas Engine.

viz.:—1st, to obtain simultaneously the indicated and the brake horse-power; 2nd, to obtain simultaneously the indicated and the electrical horse-power.

The following instruments were used by me in obtaining data for my results, viz.:—

1. A Richard's indicator, of Elliot Brothers' make, with spring yielding $\frac{1}{8}$ of an inch per lb. of pressure per square inch, was used for taking the pressure diagram from each end of cylinder at intervals of about five minutes during the various tests for the indicated horse-power.

2. A revolution counter, of Schaffer and Budenberg's make, was fixed direct to the slide-valve shaft, whereby the exact number of revolutions was obtained.

3. A Young's tachometer, of Elliot Brothers' make, was connected to the crank-shaft, and another to the dynamo spindle, as a check on the mean revolutions per minute, and to indicate variations of speed.

Brake Tests.

Duration of test in minutes	60
Total revolutions in 60 minutes	11,016
Mean revolutions per minute (n)	183.6
Mean effective radius of brake load, in feet (r)	2.78
Mean net load or brake, in lbs. (p)	140
Brake horse-power from above $\left(\frac{2\pi r n p}{33,000}\right)$	13.6
Number of indicator cards taken	12
Mean effective pressure from 12 cards, in lbs.	64
Indicated horse-power from above	17.28
Gas used by engine in 60 minutes, in cubic feet	333
Gas consumption per brake horse-power	24.48
" " indicated	19.27
Percentage efficiency of engine $\frac{\text{brake h.p.}}{\text{i.h.p.}} \times 100$	78.7

4. A gas meter (Alder and Mackays), 80-light, sealed and certified correct by an Edinburgh gas company's official, was used to measure the gas supply for developing the power. A separate small meter was used for the pilot and ignition lights.

5. Two Fahrenheit's thermometers were employed to indicate the rise in temperature of water passed through the cylinder jacket, one being placed on the supply tank, and the other where the water left the cylinder jacket.

The following instruments and appliances, in addition to those previously mentioned, were used, viz.:—

1. *Dynamo*.—One of the fly-wheels was connected direct by belt to a Rankin-Kennedy single-magnet horseshoe compound-wound dynamo of about 8,000 watt-power, which was kept running steadily at about 800 revolutions per minute.

2. *Lamps*.—In parallel circuit with the dynamo were placed eight large incandescent lamps capable of giving

TABLE A.

Volume of Gas.	Hydrogen, H.	Carbonic Oxide, CO.	Marsh Gas, CH ₄ .	Ethylene, C ₂ H ₄ .	Tetraylene, C ₄ H ₆ .	Carbonic Acid and Oxygen.	Nitrogen.	Total.
Cubic feet in one cubic foot of gas	·441	·041	·434	·037	·018	·005	—	1·0 sub. ft.
Heat evolved per cubic foot in B.T.U.	343·82	342·03	1066·7	1677·6	3063·6	—	—	B.T.U. 745·73
Heat evolved by given amount of each	151·6	14·02	462·9	62·07	55·14	—	—	

TABLE B. — MOVEMENT OF PISTON IN PERCENTAGE OF STROKE.

—	0	5	16	25	■	45	55	65	75	85
v	0	44·5	133·5	222·6	311·5	400·5	489·5	578·5	667·5	756·5
V	404·0	448·5	537·5	626·5	715·5	804·5	893·5	982·5	1071·5	1160·2

P	—	—	159·7	124·7	107·7	87·7	77·7	66·7	53·7	43·7
$\log P$	—	—	2·203	2·1	2·03	1·94	1·89	1·84	1·78	1·73
p	57·7	—	39·7	31·7	25·7	22·7	19·7	16·5	16·7	—
$\log p$	1·76	—	1·60	1·50	1·41	1·36	1·29	1·27	1·22	—

500 candles each, with 12 amperes at 80 volts and one 16-candle lamp.

3. *Voltmeter*.—The difference of potential between the terminals was measured by a Cardew voltmeter.

4. *Current Meter*. The total current passing through all the lamps was measured by a Siemens electro dynamometer. The voltmeter and ampere-meter had been tested before leaving the Woodside Electric Works, and simultaneous readings were taken on each, every five minutes.

Tests when Driving Dynamo.

Duration of two tests combined, in minutes.	15
Revolutions of engine fly-wheel, per minute.	187·7
Mean pressure in cylinder, in lbs. per sq. in.	63·2
Indicated h.p. (from above data)	17·4
E.M.F. at lamp terminals, in volts	79
Current through all the lamps, in amperes	92
Electrical h.p. spent on all the lamps	9·74
Ratio of electrical to indicated h.p.	55·8
" " brake h.p. %	71
Gas used in cubic feet per hour (without including pilots)	333
Gas used in cubic feet per minute $\left(\frac{333}{60} \right)$	5·55
Heat equivalent of the 5·55 cubic feet of gas used per minute, in ft. lb. $(5·55 \times 691 \times 773)$	= 2,964,500
Water passed through cylinder jacket, in lb. per hour	1,272·4
Mean rise in temperature of the above water in Fah.°	55
Heat carried away by water per minute in B.T.U. $\left(\frac{1272 \times 55}{60} \right)$	= 1166
Heat equivalent in ft. lb. (1166×773)	= 901,600
Percentage of total heat carried away by jacket water $\left(\frac{901,600}{2,964,500} \right) \times 100$	= 30·4

It remains, therefore, only to estimate the heat passing away in the exhaust and scavenger strokes, and by radiation, which is done here "by difference," so that we have of the total heat due to the combustion of the gas:

I. Converted into indicated horse-power	19·2%
II. Carried away by the cooling water	30·4
III. Discharged in exhaust and scavenger strokes, and by radiation	50·4

100

Appendix I.—Determination of the Heat evolved per cubic foot of gas used during the Tests.

A sample of the gas was analysed by Mr. C. J. Wilson, F.I.C., F.C.S., and gave the following results:—

Carbonic acid and oxygen gas	·5
Carbonic oxide, CO	·1
Olefines, C ₂ H ₄ and C ₄ H ₆	5·5
Marsh gas, CH ₄	43·4
Hydrogen, H	44·1
Nitrogen (by difference)	2·4

100·0

The percentage of C₂H₄ and C₄H₆ should have been given separately, because the heat value of C₂H₄ is only about half that of C₄H₆ for a given volume. Assuming, however, that two-thirds of the olefines is C₂H₄ and one-third is C₄H₆ (which is probably not far from correct), we have the results shown in Table A.

This is the amount of heat evolved by the complete combustion of one cubic foot of the gas measured at 14·7 lb. pressure, and 32° F., but the pressure was 14·8 lb. per square inch, and the temperature, 67° F., hence the heat evolved per cubic foot of the gas used will be

$$= 745·7 \times \frac{14·7}{14·8} \left(\frac{460 + 32}{460 + 67} \right) = 691 \text{ B.T.U.}$$

Taking one B.T.U. as equal to 773 ft. lb., the heat evolved by the complete combustion of one cubic foot of the gas is equivalent to 691 B.T.U. $\times 773 = 534,500$ ft. lb. Heat evolved by complete combustion of

1 cubic foot gas	= 534,500 ft. lb.
Gas used in cubic feet per brake horse-power, per hour	= 34·48
Gas used equivalent in ft. lb. $(534,500 \times 34·48)$	= 13,085,000
One horse-power in ft. lb. per hour $(33,000 \times 60)$	= 1,980,000
Practical efficiency of engine $\left(\frac{1,980,000}{13,085,000} \right) \times 100$	= 15·1
Gas used in cubic feet per indicated horse-power per hour	= 19·37
Gas used equivalent in ft. lb. $(534,500 \times 19·37)$	= 10,300,000
Absolute efficiency of engine $\left(\frac{1,980,000}{10,300,000} \right) \times 100$	= 19·2%

Appendix II.

Determination of equations for compression and expansion curves from the indicator diagram attached (which is a sample of a large number taken from both ends of the cylinder).

Let V = Volume in cubic inches occupied by the gas at any part of stroke.

L = Volume in cubic inches through which piston has swept from end of stroke.

$V = v + 404$ (where 404 cubic inches is the volume of clearance space at back end of cylinder).

Total volume swept by piston = 890 cubic inches.

P = absolute pressure on expansion curve.

p = absolute pressure on compression curve (see Table B).

THE "GRIFFIN" GAS ENGINE.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and last week we give that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation and we hope soon to have ready that of PROF. D. E. HUGHES, and

COMMISSIONS.

This is one of the most interesting, and at the same time one of the most dangerous, subjects to discuss. Business sees far too much of interest, discounts, and commissions, and yet all this *finesse* seems necessitated by the modern methods of trading. "That is the lowest price nett" is a phrase seldom heard, but if it is ever uttered, it is usually a case of repentance before the hour. The purchaser takes the "nett" price and the time as well, chuckling to himself that he has this morning done a good stroke of business. It is, however, almost entirely of commissions that we desire to write. When are commissions to be expected, and to whom should they be paid? They may be, and frequently are, claimed by those who have no legitimate right to them, and they are as frequently paid to such parties, though with a mental reservation and possibly an unspoken opinion on the part of the payer. Political economists are happy when discussing questions relating to division of labour, and we all remember the gusto with which one of the greatest of them described the manufacture of pins. But may there not be too great a division of labour, and hence, in the matter of business, too many middlemen? The manufacturer, for example, seldom comes directly into contact with the consumer, and as there must be a profit to every middleman between the two, the last selling price may be something very different to the manufacturer's selling price. Another question might appropriately be dragged in here—that of price lists. To the outsider a price list is usually a hidden mystery. The quotations of discount "off" the list vary considerably to the individuals seeking information, and among the reasons why the real prices and the list prices differ so much is this one of commissions. Consider two claimants for commission. A is a man who thinks B ought to install the electric light into his house, and approaches him on the subject, expounding its advantages, and ultimately, after a good deal of trouble, time, and expense, gets B into the right frame of mind. B asks A the firm or person he recommends, and is told, C. On the other hand, suppose that while B is in the right frame of mind he happens to meet D, and in conversation speaks of what he is thinking, as is not unfrequently the case, D hears and casually suggests C, or, it may be, rushes off to C, telling him of the purpose of B, and claiming commission. The work is put into C's hands, and A also claims commission. Is C to pay both or only one, and, if so, which one? There is not the slightest doubt in the case specified but that A has really done the work, and that D, if he gets commission, gets paid for work he has not done. The case may be still more complicated, in that B applies to C direct, mentioning neither the name of A nor D, but of some client of C's, and, after the work is done, A and D, or either, claims com-

mission. It may be, and often is the case, that B, applying direct, gets better terms than if it is known a commission has to be paid. So that if the claim for com. is subsequently met, C may be a considerable loser. We know of a case relating to the lighting of the yacht of a wealthy man, when six or seven commissions were demanded, and had to be paid. The contractor was bluntly told price was no object, but the payment of these commissions was a *sine qua non*. No doubt the amount for the electric lighting was lumped with other items for fitting, so that the owner never knew, and never will know, what the work cost him. If we might venture to surmise, the contractor did not get for himself more than 50 per cent. of his bill. It is said that backsheesh is all-powerful at Constantinople and in the East generally; but we are bound to say, from a considerable experience, that the *argumentum ad hominem* is quite as well understood in England as elsewhere, and, of course, all goes under the name of commission. Firms of repute, as well as individuals, are beginning to make a trade in, and at every opportunity to claim, commission; and this in cases where they have no power to divert business in any particular direction. It is impossible to be more definite in discussing this question, because remarks intended to apply generally would undoubtedly be applied to individuals, and at present it is neither our wish nor our intention to single out individuals for animadversion. The principle of commissions is a good one when not carried to excess; but, like all other good things, it may conduce to greater harm than good if not taken in moderation. With the advent of the millenium, commissions will cease; at present they are a necessary evil.

MAXIM-WESTON.

There was a lively meeting of shareholders on Wednesday to hear the report of the Committee of Investigation, but there are two sides to the moral, just as there were two sides in the case of the boys and the frogs. The shareholders have supported the Committee and carried their report, which no doubt produced fun enough for the boys, but what about that chameleonic chairman and his colleagues? Will they be in the position of the frogs, and will henceforth their place in electric light companies know them no more? They have had full swing for some years, have, according to their own showing, rescued the company from the Slough of Despond—and paid dividends. It were not wise, perhaps, to enquire too closely into the how they managed to pay dividends, though sarcastic folks say it is an easy matter to do so when you write off your capital, call up fresh capital, make your own balance-sheet, and in it put your own value upon stock, etc. Some, indeed, have been rash enough to suppose the stock has been valued at its list

retail price, and not at its actual cost price; but, of course, this is purely imaginary. We are not quite sure but that Mr. Hugh Watt, M.P., will regret having left his unique sphere among mining companies to rescue from the clutch of the official receiver an electric light company. Speculators in mining properties expect a few ups and downs, and are inured to a variety of changes rather foreign to electrical work, so that they are somewhat indifferent to the vagaries of directors. Shareholders in electrical companies have not yet been able to emulate the mining properties in getting hold occasionally of undoubtedly good paying concerns, hence their anxiety to save from the hands of the spoiler what few bawbees may be left.

The report of the committee will be found in another column. It is as suggestive from what it does not say as from what it does say. Fancy a duly elected committee not being able to get hold of the minute-book. What a bold step to take to say the balance-sheet submitted was misleading; that one of the directors was not duly elected; and that the value on the stock was scarcely accurate. Pleasant reading this for those who had pinned their faith upon the success of the company. It seems, too, after all, that the Watt dynamo and lamp are not so entirely separate from the company's operations. The committee and the shareholders hold that these patents are really part of the company's assets, though they say it in rather an ambiguous manner. All along the line the management is condemned, and we believe justly. The business has cost too much, and, shall we add, the work that has been done has seldom been done sufficiently well to please the fastidious tastes of the critics. Our crime in the eyes of the management is very gross. We declared against the action in relation to the City lighting; we say that the workmanship of installations we know of is bad, that new work is obtained at a very great cost, and then only by tempting people by ruinously low prices, so that the company is being bled both ways. A company so managed is detrimental every way, whether we consider the shareholders, buyers, or the industry of which it forms part. There is in our estimation no chance of renovating the company by the addition of new blood on the directorate. The only plan is to sweep away the present directors, and commence *de novo*.

EXPERIMENTS ILLUSTRATING THE PRINCIPLE OF THE DYNAMO.

BY GEO. M. HOPKINS.

The great development of electricity in recent years, especially in the line of electric illumination, has served to add lustre to the name of the immortal Faraday, and to show with what wonderful completeness he exhausted the subject of magneto-electric induction. Since the close of his investigations no new principles have been discovered. Physicists and electrical inventors have merely amplified

his discoveries and inventions, and applied them to practical uses. The number of those who are familiar with the discoveries of Faraday and their bearing on modern electrical science is not only large, but rapidly increasing, but there are those who are still learners, to whom new things, or old things placed in a new light, are ever welcome. To such, the single experiments here given may be an aid to the understanding of induction as developed in dynamos and motors.

Anyone at all acquainted with electrical phenomena knows that a hardened steel bar, surrounded by a coil of wire, which is traversed by a electric current becomes permanently magnetic. It is perhaps unnecessary to

FIGS. 1 AND 2.

reiterate the accepted theories of this action, as they are well established, and appear in almost every text-book of physics. The fundamental magneto-electrical experiment of Faraday was exactly the reverse of the operation of producing a magnet by means of an electrical current. That is, it was the production of an electrical current by means of a magnet and coil. In the first instance, the magnetising power of the electric current is employed to bring about the molecular change in the steel bar, which manifests itself in polarity. In the second instance, the magnetised steel bar is made to generate an electric current in the wire of the coil. In the first instance, the current moving in the wire of the coil induced magnetism in the steel. In the second instance, the movement of the magnetised steel within the coil induced a current in the wire.

The method of magnetising a bar of steel is clearly shown in Fig. 1, in which *a* is a helix of six or eight ohms resistance, *b* the bar of hardened steel, and *c* a battery of four or five elements. A key is placed in the circuit, but the ends of the wires may be made to serve the same purpose. By closing and opening the circuit while the steel bar is within the coil as shown, the bar instantly becomes magnetic. When the coil is disconnected from the battery and connected with a galvanometer, *d*, as shown in Fig. 2,

FIG. 3.

and the magnet *b*, is suddenly inserted in the coil, the needle of the galvanometer will be deflected, but the action is only momentary. The needle returns immediately to the point of starting. When the magnet is quickly withdrawn from the coil, the needle is deflected for an instant, but in the opposite direction, and, as before, it immediately returns to the point of starting. It is obvious that if these electric pulsations can be made with sufficient rapidity to render them practically continuous, and if they can be corrected so that pulsations of the same name will always flow in the same direction, the current thus produced may be utilised.

Before proceeding further with the consideration of magneto electric induction, it will be necessary to briefly examine the subject of magnetic induction, as it is intimately connected with the action of the dynamo. In Fig. 3 is illustrated the usual experiment exhibiting this phenomenon. An electro-magnet is connected with a suitable battery, and a bar of soft iron is held near, but not in contact with one of the poles of the magnet. It becomes magnetic by induction, the end nearest the magnet being of a name different from that of the pole by which the in-

FIG. 4.

duction is effected. The end of the bar remote from the magnet exhibits magnetism like that of the magnet pole of the magnet.

The relation of magnetic induction to magneto-electric induction is clearly shown by the experiment illustrated in Fig. 4. In this case two electro-magnets are arranged with their poles in contact. One of them is connected with a galvanometer, and the other with a battery. When the circuit of the upper magnet is closed, the core of that magnet becomes magnetic, the core of the lower magnet becomes magnetic by induction, and the galvanometer needle is deflected. When the circuit of the upper magnet is broken, the galvanometer needle is deflected in the opposite direction, showing that the results are precisely the same as in the experiment illustrated by Fig. 2. In

FIG. 5.

this case no mechanical movement is necessary, as the magnetism is introduced into the coils of the lower magnet by induction. It is thus shown that it is not necessary to move any matter to secure magneto-electric induction.

In Fig. 5 is shown an arrangement of electro-magnets, in which one is fixed, while the other can be revolved. It is a device intended simply for showing how two ordinary electro-magnets may be utilised to advantage in experiments in induction.

To the polar extremities of the fixed magnet is fitted a wooden cross-bar, having in its centre an aperture for receiving the vertical spindle, the lower end of which is

journalled in the clamp that holds the fixed magnet to the base. The upper end of the spindle is provided with a yoke for holding the movable magnet. The cross-bar which clamps the magnet in the yoke is held in place by two screws (as shown in Fig 7), and to the centre of the cross bar is attached a wooden cylinder, *c*, axially in line with the spindle. To the wooden cylinder are secured two curved brass plates, which are connected electrically with the terminals of the coils, *a a'*, of the movable magnet, one plate to each coil. Two strips of copper, *g g'*, held upon opposite sides of the cylinder, complete the commutator. The copper strips are connected with any device capable of indicating a current in the present case an electric bell and the coils, *a a'*, of the fixed magnet are connected with the battery, *c*.

FIG. 6.

By turning the upper magnet, the following phenomena will be observed: 1. When, by turning the movable magnet, its poles are pulled away from the fixed magnet, the departure of the induced magnetism from the core of the movable magnet produces an electric pulsation in the coil, which operates the electric bell. When, by a continued movement of the magnet in the same direction, the poles exchange position, another electrical impulse will be induced, and the bell will be again operated. 2 By examining these impulses by means of a galvanometer introduced into the circuit, it will be found that they are of the same name. 3. When the magnet is turned a little faster, these two impulses will blend into one, so that for each half of the revolution of the magnet the bell yields but one stroke. By whirling the magnet quite rapidly, the current through the bell magnet is made practically continuous, so that the bell armature is drawn forward toward the magnet and held there.

FIG. 8.

From what has been said, it will be seen that all of the positive electrical impulses are generated upon one side of the poles of the fixed magnet, and all the negative impulses are generated upon the other side of the fixed magnet, and that the curved plates of the commutator conduct all of the positive electrical impulses to one of the strips, *g g'*, and all of the negative impulses to the other strip.

In Fig. 8 is shown an arrangement of connections to convert the device into a motor.—*Scientific American*.

ELECTRICAL TRAMWAYS: THE BESSBROOK AND NEWRY TRAMWAY.*

BY EDWARD HOPKINSON, M.A., D.S.C., ASSOC. M. INST. C.E.

(Continued from page 378.)

MOTORS.

Each locomotive car is fitted with an Edison-Hopkinson dynamo-motor. As previously mentioned, the motor is fixed on the leading bogie, and is entirely independent of the body of the car. The armature shaft carries a double helical-toothed steel pinion, 6.05 inches in diameter, gearing into a steel wheel 21.08 inches diameter, carried on a small counter-shaft running in bearings fixed on the bed of the motor. The shaft also carries a chain pinion-wheel of steel, 8.8 inches diameter, on the extended boss of which the helical-toothed wheel is keyed. The chain pinion drives with chain-gear on to a wheel 21 inches in diameter, keyed on to the back axle of the bogie, the wheels of which are 28 inches in diameter. This gives a ratio of gear of 8.3 to 1; hence a speed of one mile per hour corresponds to 100 revolutions per minute of the dynamo axle. To give the necessary adhesion, the axles are coupled with outside connecting rods.

The motors are series-wound with such a number of convolutions that the magnets are nearly saturated with 72 amperes, which is also the normal current for the armature. The resistance of the magnets is 0.113 ohm, and of the armature 0.112 ohm; hence, if the potential between the terminals be 220 volts, the electrical efficiency with the normal current is 92.6 per cent., and the commercial efficiency 90.7 per cent., the power developed being nearly 20 horse-power. In actual work the power of the motor frequently exceeds this amount. To transmit this power

with the car running at, say, seven miles per hour, the tension of the chain would be 1,430 lb., and the speed 460 ft. per minute. At starting on a gradient with the full load the tension may reach 3,400 lb., and with the car running at the maximum rate, the speed may reach 1,300 ft. per minute. Considerable difficulty was experienced in obtaining a chain strong enough to stand the high working tension, and at the same time not unduly heavy for running at the high speed. Several chains of the well-known tricycle form were tried. In these the inside link is fitted with two tubes through which the pins of the outside link pass, so as to give a wearing surface across the full width of the chain. The tube is protected by a loose roller, intended also to reduce the friction. It was found, however, that the impact of the chain against the teeth of the wheel flattened out the rollers, and ultimately split them; also, sooner or later, the tube became loose in the inside links, and began to wear. A steel chain, specially constructed by Mr. Hans Renold, was finally tried, in which the tubes were keyed as well as riveted in the inner links, and the pins in the outer, and the rollers abandoned (Fig. 8). The average breaking-stress of the steel is 152 lb. per square millimetre (43½ tons per square inch).

Pitch of chain ..	= 2.125 inches
Weight ..	= 8.5 lb. per linear foot.
Strength of pins against shear ..	= 13.8 tons.
" outside links ..	= 10.2 "
" inside ..	= 14.8 "

The wearing surface per foot of chain is 16 square inches, whereas in the ordinary bowl or stud chain of the same strength the wearing surface would not exceed 2.5 square

* Paper read before the Institute of Civil Engineers, and reported by permission from the Transactions of the Institute.

The trains are commonly composed of one locomotive car and three or four trucks, but frequently a second passenger car is coupled, or the number of trucks increased to six. Thus a gross load of 30 tons is constantly drawn at a speed of six or seven miles per hour, on a gradient of 1 in 50.

EFFICIENCY EXPERIMENTS.

In order to test the efficiency of all the component parts under various conditions of load, several series of observations were made as the car travelled from Newry to Bessbrook with six, four, and no trucks respectively. The flow of water, the potential of the conductor, and the speed of the car were ascertained at frequent intervals, and the results plotted in the form of curves, with the time as abscissa. From these observations, and the known resistances of the generator, motor, and conductor, the loss in the several portions of the system, and the actual power developed by the motor, can be readily calculated, and the results similarly shown in a graphic form. The points representing actual observations are joined by straight lines, though no doubt a line of continuous curvature would more

and the axis of abscissas. The results are given for the three series of curves in Tables I., II., and III. in the Appendix.

Table IV. in the Appendix also gives the results of the integration for the three journeys, showing the work done by the water, the electrical energy developed by the generator, the loss in leakage, resistance of line, magnets and armature of generator and motor respectively, and the mechanical work done by the motor, all expressed in foot lbs. Table V. gives the results in Table IV. tabulated as percentages of the total energy of the water, and also of the electrical work done by the generator. It will be observed that the efficiency of the whole combination varies from 26.1 per cent. for the light load to 41.3 per cent. for the heavy load, whereas the efficiency of the electrical portion varies from 69.4 per cent. for the heavy load to 76.8 per cent. for the light load. This is explained entirely by the very low efficiency of the turbine when running with a light load. When loaded to nearly its maximum capacity, its efficiency is 60 per cent., which is not unfavourable, considering that the load is constantly

Fig. 3

accurately represent the fact; but the method employed has the advantage of distinguishing at a glance observation from interpolation.

The curves, Plate 1, Fig. 1, give the results for a journey with a gross load of 28 tons 12 cwt. 3 qrs., including the locomotive car.

The curves, Fig. 2, for a gross load of 21 tons 18 cwt.

The curves, Fig. 3, for a gross load of 8 tons 16 cwt.

Hitherto, writers on electrical locomotion have considered the question of mechanical efficiency from individual observations made at a given instant, when the conditions might or might not be favourable. By a suitable choice of conditions it is very easy to deduce extraordinary high figures of efficiency for electrical working, but such figures are misleading, and not a fair basis of comparison with other modes of locomotion. Since the conditions are constantly varying between very wide limits, any calculation of efficiency ought to take account of the average conditions, or, in other words, the results of a series of individual observations taken at intervals ought to be integrated in respect of time. The curves enable this to be readily done by determining the areas bounded by them

varying, and that the friction of the shafts, belts, and dynamos, as also the power required to drive the governor, are included. Considering the problem as an electrical one only, it appears that the efficiency does not vary greatly with the load, falling only from 76.8 per cent. to 69.4 per cent., as the load is more than trebled. Taking the average of the three journeys.

Electrical efficiency	72.7 per cent.
.. loss in generator	8.6 ..
.. .. leakage	5.7 ..
.. .. line resistance	6.6 ..
.. .. motor	7.7 ..

The loss as given above in the generator and motor does not include the friction of the bearings nor the power required to turn the armature in the excited fields when no current is passing through it, both of which, however, are very small.

(To be continued.)

* It will be observed in the tables that the totals given do not always correspond exactly with the sum of the components. This arises from the curves being separately integrated. The error of about 1 per cent. is a measure of the accuracy of the method.

"compound up," so the primary pressure should be increased an amount equal to half the full load loss, so as to split the difference. He the speaker did not think the importance of motors was sufficiently taken into account. One difficulty was in starting alternating motors. A laminated field exciter can be used to start the motor, and switched over when the right speed is reached. Little was known about insulation on alternating circuits. It was possible that insulation which gave way with 2,000 volts continuous would stand the same alternating, the harm done in one direction being undone next alternation, and so on. As to the drawback of being unable to use storage with alternating systems, he could only quote Mr. Morley's dictum: "The great advantage of alternating currents is, people cannot go and put in accumulators." The weak point of Mr. Crompton's system was the high pressure led into houses. He believed alternating currents were best for scattered lighting with overhead wires: direct parallel for dense districts, and step-down dynamos, or "dynamotors," for such cases as that taken by the author. Dynamotors need little or no attention, and they will regulate, or even compound up, with a varying primary pressure. They get over the high pressure difficulty, and have the doubtful advantage of admitting accumulators. The safety of people on transformer secondaries had been already considered. To make the installation safe, however, none of the current should be earthed permanently, but a contact should occasionally be automatically made between first one terminal and earth, then the other terminal and earth. In case of a leak, a bell would be left ringing, no further contacts being made. In the case of alternating currents, the contacts are made through a toothed wheel synchronising with the machines, so that capacity shocks do not interfere with the working. If a man makes an earth contact, he is then immediately shunted to earth and set free.

Major-General Webber, C.B., R.E., drew attention to the difficulties he foresaw in connection with Mr. Crompton's proposed subways. Such an arrangement would not be watertight, and after two years the accumulation of detritus would cause the insulation to disappear. The bare conductors could only be got at by opening up the roadway except at the connection boxes, and he could not consider the maintenance of any underground conductors that were not capable of being withdrawn in the same way as telegraph conductors were laid down, a purpose for which the Callender bitumen concrete tube was specially suitable. He considered Mr. Crompton's estimate of 20 yards of main cable required for every house as excessive by three yards.

Mr. Sidney P. Walker took the subject of the paper as leading onward towards the progress in electric lighting which engineers were looking forward to in the current year, and the question of accumulators v. transformers was applicable to installations of less than 10,000 lights. There was progress needed in the lamp itself before those matters could give material help. The introduction by Mr. Swan of a 200-volt lamp would quarter the cost of the copper in the cable, and a 400-volt lamp would quarter it again. He was afraid that the varied voltages of the lamps at present in use was the result of progress, and could not be helped. His experience led him to consider that the essential thing to be studied commercially was what was known as the efficiency of the service. When a good thing was produced, a sufficient number of customers would always come forward to pay for it, but they would not put up with break-downs every now and then such as had been referred to by Sir David Salomon. A consumer might be told that the efficiency was 99.9 per cent., and he might take an interest in it, but if the system broke down he would vote it as being a marvellous nuisance, though it was a marvellous thing. The difficulty with transformers was that before the service of 2,000 volts could be properly dealt with, the problem of providing efficient insulation for it must be faced. The service must not be insulated for temporary use, but for a permanency as long as the system lasted. The difference in the insulation—heavy and light for the same size of conductor did not provide for a pressure of 2,000 volts. He agreed with General Webber as to the difficulties to be expected with the subways, and he suggested that, instead of using a large cable, it would be better to employ small cables, so that each could have its own small engine and small dynamo. His experience of continuous current dynamos in parallel was that they did not work properly together. If, in working with two such dynamos coupled in parallel, one happened to be half a volt below the other, it would take much more current than its fellow because the second could not deliver until the first one had ceased to compound.

Mr. Robert Hammond considered that the question raised by Mr. Crompton was the crucial problem that confronted all those who had to do with central station work, and which had confronted them in the immediate past. The installation at Eastbourne had been mentioned, and he might state that some two years ago it was suggested to light the Town Hall there in such a way that any portion of the lamps could be running, or the whole 300 at the same time. By the grouping arrangement, under which the system was then working, such conditions were impossible, and it was necessary to consider whether it was best to put batteries into the Town Hall which could be charged with the high-tension current, or to use converters or transformers. Transformers were decided upon, and the lighting of the Town Hall was carried out, had continued to work satisfactorily, and he looked to the installation with great pride. In reading Mr. Crompton's paper he was surprised to find it stated that the installations at Eastbourne and elsewhere had been "unwisely carried out in a temporary manner for the purpose of popularising the electric lighting, and inspiring the confidence of the public in supply companies as a form of investment." If in the Eastbourne installation they had struggled for anything during the last five or six years, it had been to pay a dividend to those who had invested their money in the concern, and had Mr. Crompton seen the list of shareholders he would have hesitated before making what he could not help feeling was an unkind remark. In one paragraph Mr. Crompton said, "It is hardly to be wondered at that what little knowledge exists on this subject should be confined to the few who have lighting stations under their immediate charge,"

while in the next he in effect said, Do not take any notice of Eastbourne or Brighton, because they are only a set of advertisers. As Mr. Crompton had taken no notice of those installations in his paper, he (Mr. Hammond) would relate a few facts connected with those two central stations, because they might not be gathered from Mr. Crompton in his reply to the discussion. He had already said that transformers were used, and some 2,000 or 3,000 lights were supplied. He had learned that in starting a central station, scattered lights must be at first provided for, and then gradual additions of fifty or 100 lights might be expected. In estimating for a London central station he had had again to consider whether batteries or transformers should be used, and again he had come to the conclusion that transformers were the best. His order had not been placed, and if Mr. Crompton could convince him that batteries were the best, he was prepared to adopt it. Mr. Crompton had stated that three shifts of men were necessary with transformers, but that was not so, for he had himself seen the central station at Brighton working at its busiest time, and then one engine after another was put down according to the load, and the labour expended was absolutely proportional to the load on the current. People who said that with a transformer system it was necessary to have three times the normal staff, were talking of what they would know more about if they went down to Brighton and Eastbourne and saw what was done. Therefore, in point of economy, Mr. Crompton was as far out as he was in regard to the motives that had inspired those installations for the past five or six years. He would say nothing about the Grosvenor Gallery installation, as the people connected with it were very well able to take care of themselves. As to the reserve offered in the battery system, that was only a chemical reserve, and it was a question whether a chemical reserve was better than a mechanical reserve. At Brighton a second engine was always ready, with steam up, to come in at any moment. He asked what probability there was that a steam engine which was well looked after would burst up without any warning. His experience was that a warning was always given, and if the pressure of the attendant detected a leak, it was attended to. No stoppage had ever occurred through not being able to bring in the reserve power, to do which there was always plenty of time, and the advantage of having a reliable and continuous power rendered the introduction of those wretched accumulators on the circuit unnecessary. Some of the outlying districts were served by accumulators, a fact, perhaps, unknown to Mr. Crompton, as he had not been down to see, but his experience of them was such that he felt they were the one portion of the system to be afraid of. Accumulators were a splendid thing on paper, but in practice they only gave a day-to-day absolute efficiency of 60 per cent., as against the 80 per cent. stated by Mr. Crompton. He could show converters at Eastbourne which gave 95 per cent. efficiency, and any transformer which gave 30 per cent. must be in atrociously bad one. He was anxious to hear what Professor Forbes could say about what was done in America, and whether converters with light loads ever fell from their high efficiency down to 30 per cent. when they were thoroughly well constructed. As to depreciation, experience showed that it was not necessary to put down 10 per cent. on that account for converters. Such an amount was not required for dynamos, and why was it necessary in the silent converter, which had no movable parts, while only 15 per cent. was set down for the depreciation of accumulators? On those four points, therefore, of the load, reliability, efficiency, and depreciation, his experience was dead against Mr. Crompton's statements. One might imagine when Mr. Crompton said that at "Eastbourne, Brighton, and, in fact, all those which distributed by means of overhead wires," the system at Eastbourne was overhead. That was not so, for there were some seven miles of underground mains used, and in reply to the remark just made, that the insulation must break down at or under 2,000 volts, he could only say that the charging pressure was 2,000 volts, which were passed through those mains, and they lived through it all.

Mr. A. P. Trotter thought that Mr. Crompton had shaken the faith of many of those who relied on transformers, and he, for one, would not like to say that batteries would not be the system of the future, especially when the time came that motors were generally used. Great improvements had been made in the life and efficiency of batteries. Spare dynamos and engines should always be kept in reserve, and it was discreditable that so few installations existed with such reserve, as its absence had prejudicially affected the progress of electric lighting more than anything else. He considered it unfair to transformers to assume that two out of every three houses would at no distant date take the light.

The discussion was then adjourned until April 26.

PARLIAMENTARY INTELLIGENCE.

THE ELECTRIC LIGHTING ACT (1882) AMENDMENT BILL.

HOUSE OF LORDS.—MONDAY, APRIL 23.

The House went into Committee upon this Bill.

On Clause 2.

The **Earl of Camperdown** moved to omit the words "The goal—wilt of the business and of" on the ground that they rendered uncertain the elements of value in the property of the companies to be taken over. He desired at the same time that at the expiration of the period during which the companies' privileges were to endure, then plant and material should be valued as being *in situ* and as suitable for the purposes for which they were intended, instead of being taken over at the "old iron" value.

The **Earl of Crawford** observed that inasmuch as it was understood that the noble and learned lord opposite intended to propose at

been for that letter, I am quite certain a large number of gentlemen present at the last meeting would not have voted for the committee. With regard to the increase on the item of patents, I think I had better give you the three items that were increased in the balance sheet of 1887 as compared with 1886. In 1886 the patent account was £38,229. 17s. 1d., whereas in 1887 it was written up and placed to credit as an asset to the extent of £40,737 1s. 1d. That increase is made up as follows—Cash to Henslow, £44; wages at works, £718. 4s. Then we have salaries that mean Mr. Watt's experimental works, £750, Mr. Telf £200, total £950, written up to credit of patents. Next there are goods used in experiments £325, salaries, £100 of the Secretary's salary, £270 office expenses, and £100 general office expenses. These are the items by which your patent account was increased from £38,229. 17s. 1d. in 1886 to £40,737 1s. 1d. in 1887. The stock of machinery, tools, &c., at the factory was £13,440 in 1886, whereas in 1887 it was written up to £19,817; the stock plant machinery, and tools are £2,970. 4s. 9d. in 1886 and £3,603. 15s. 2d. in 1887. In other words the stock, patents, and machinery, down at £54,640 in 1886, were written up to £64,158 in 1887. But although we had the stock book has been written up, and increased values placed against machines and other things, as compared with 1886 your committee failed to find the increased value in the stock as compared with 1886. Their own opinion is that instead of being written up, a certain amount should be written off. We very much regret that at the preliminary meetings of the committee a great deal of our time was wasted. I think that to us as commercial men, that was a pity. There were a great many excuses with regard to the books, the Secretary being out, and Mr. Howell being out, and we had great difficulty in finding either the Secretary or Mr. Howell, and, at times, Mr. Watt. The third paragraph of the report relates to the Directors. We held we have not gone into any personal matter between Mr. Swaby and Mr. Watt, but Mr. Swaby holds a qualification, and should have retained his seat at the Board. What we find is this: Mr. Brown, the late Director, retired from the Board on March 3, and from February 22 to April 4 he disposed of 1,275 shares. On March 3, after Mr. Brown's retirement, Mr. Swaby not attending the offices of the Company, we consequently held that all the business done from that time until the present is done illegally, because there was not a quorum of the Board to transact any business. Mr. Brown retired on March 3, and on March 6 Mr. Howell had 250 shares transferred to him by the Chairman but as there was no Director to sit with Mr. Watt, the Board could not accept Mr. Howell as a Director nor transact any business, according to our opinion of the articles of association. Coming to the fifth paragraph of the report, we say the Board ought to be strengthened. We very much regret that shareholders have not been put in possession of a copy of our report. We made a request to the Secretary that he would address us a set of envelopes, but the Secretary has refused to furnish us with them, otherwise the report would have been in your hands. The notice convening the meeting was only sent out when the committee sent a request to the Secretary to do so. We pointed out that according to the articles of association notice ought to be sent to every shareholder, and that the notice should state that the object of the meeting was to finish the business left unfinished at the meeting on March 23, and that a paragraph had better be inserted as to receiving the Committee's report. All reference to the business and the reception of the Committee's report was stationarily avoided. We now come to the most important point of the whole business—that is, that we consider that Mr. Watt should only hold the patents for the Watt dynamo and the Watt arc and incandescent lamps in trust for the Company. He has gained what experience he has in connection with this Company, he has used part of his salary in the experiments, he has used our offices, he has used our works, he has used our machinery, he has used our wages in connection with all these experiments, and we hold that the patents are held, and should only be held, in trust by him for the benefit of this Company. I beg to move the adoption of the report of the Committee.

Mr. G. W. Hilyard, a member of the committee, in seconding the adoption of the report, said he wished it to be understood that he desired to say nothing against the Maximo, or the Weston, or the Watt patent. He held the opinion that, in the future, the electric lighting companies would be much sought after. The business of the Committee had been to look into the accounts. The amount of turnover in 1887 was stated to be £7,500 in round figures, and although he did not complain of that in itself, he did complain of the cost at which the business had been done. He held that there was a loss on last year's working of £2,000.

Mr. Hugh Watt: I think I may state at once that, after consultation, we can do almost nothing at this meeting. We cannot, at the moment, say who are Directors of the Company. Either Mr. Brown, Mr. Swaby and myself, or Mr. Brown and myself, or Mr. Swaby and myself, or Mr. Howell and myself, or Mr. Howell, Mr. Swaby and myself may be; but it is purely a legal question turning upon the articles of association, so that it is quite impossible for you to determine who the Board are and it is quite impossible, I am told, for this meeting to strengthen the Board. That is a point I should like to refer at once. Personally, I have no animus against Mr. Swaby, Mr. Brown, or anybody else, I have done my best for the Company. (A Voice: "For yourself.") Very well, I am afraid if that is your opinion, Mr. Watt, you must blame Mr. Swaby. He will agree with me in this, that some time ago, owing to other engagements, and feeling the business too heavy, I was anxious to retire, and I think no one more than Mr. Swaby thought it was in the interest of the Company that I should remain, and Mr. Swaby more than Mr. Brown, pressed me into an engagement. That engagement, gentlemen, is entirely at your disposal. I think I have said before, and I say now, that if Mr. Swaby, his friends, or anybody else, are willing to take over the Company, I have no objection. I have some 8,000 or 9,000 shares, and, from first to last, I have made no money out of the Company, notwithstanding the fact that I have drawn £2,000 a year for my services. At the last meeting I had with

the committee I said I was willing to give up a large portion of my remuneration to a manager who would relieve me of many of the details. I was willing to pay him out of my pocket. The last meeting of the committee was held on April 17. At that meeting I made a statement to that effect, and stated also that Mr. Howell had cost the Company nothing—that I had paid him myself. Of course I am not going to say anything invidious with regard to the Board, because, as I stated on advice, the Board consists of certain gentlemen, according to the constitution to be placed on the articles. We do not know positively who the Board are. It is essential, and Mr. Klenck has sufficient experience of companies to agree with me, that we adhere strictly to the articles of association. It is there provided that seven days' notice before the annual meeting shall be given of new directors. Do not suppose for a moment that I stand in the way in the matter of new directors. With regard to the business we are in this position, that massed advances which can be produced cheaper than ours have been made in 1887, we found it impossible to secure a great many contracts, which judging from the experience of 1886, we had a right to expect. We are consequently in the position as regards turnover as Mr. Hilyard has stated. But, if I may pass to a question of account, this I will say: no doubt we have added to the patents account by the amount stated. I stated that at the last meeting, but if you consider the same set down under that item is in excess of what it should be, then it must be dealt with in the working expenses. We have most carefully gone into that point. No doubt I have gained experience with this Company, but that experience has not enabled me to work out the Watt system, because I tell you frankly and fairly that the original plans of the Watt system were not of my initiation. They were submitted to me, and I financed a certain amount in connection with them on the distinct condition that the Maxim Company were to benefit thereby. The committee seem to say that the company is nothing without these patents. I say that the patents were brought to me, and Mr. Swaby, even more than Mr. Brown, wanted me to arrange to secure them originally.

Mr. Swaby: I have to deny that.

The Chairman: Then I say the minute was entered relating to it. Mr. Swaby was present, and he is not dissenting. I wish to make a perfectly fair statement, and the future of this Company depends entirely upon our arrangements. The provisional arrangement came to with regard to this patent was that you were to make the machines, if you sold them, you were to pay a certain amount of royalty for the plans and specifications put into your hands. If you sold none, you paid nothing. I mention this because I am not aware of any such patent having been arranged on such terms before. Now I come to the committee, and I have in my memorandum book here the result of a conversation, a very long one, which I had with the committee on April 17. That meeting was preceded by a long conversation as to the accounts of the Company, and Mr. Hilyard distinctly avowed that, in his opinion, there was a loss. The general account was prepared on the advice of the auditors and the professional accountant who keeps the books, and all I can say is that, that the more you debit working expenses with amounts incurred in experimental work the less will be your chance of a dividend and profit. That was a question for the shareholders. Let us turn to other companies. In one year I am told that another company debited patents up to a sum amounting to tens of thousands of pounds. I do not say that that was an excessive sum, I am not going to discuss their business; but I say that the sums we have charged to patents, except my own proportion and the manager's, and one or two of the superior officials, have been totaled hour by hour at so much per hour. That is what has been done. The plant used, that is, in winding and unwinding, and so forth—principally the Maxim machine—has expended a certain amount of wire. It is for the shareholders to decide whether our estimates in this matter are correct or not. I think that in a matter of this kind—Mr. Hilyard will agree with me—that is a subject for an expert, hardly a matter for hard-headed business men—where we are dealing with scientific and mechanical as well as commercial principles, it is rather a curious thing to do to place Mr. Hilyard's opinion against mine. I say this with all the deference to him. I have had five or six years' experience in these matters, as he has said, and the result is that my conclusion is what have already stated I have arrived at. Our accounts are prepared in the same way as those of other electrical companies. What I say before was that we cannot take this business like a better business, where you produce the same article year after year. You must either work the van of electricity or you must not. Now, regarding the Watt patents, if you do not have them you will lose them, and providing my advances are paid they will be taken out of my hands altogether. You have made certain machines, and expended a certain amount on them. Under the arrangement made, which will be carried out, all machines and lamp-makers remain the property of the Company, or, if you do not want them, your expenditure will be paid you, and there is an end of it.

A Shareholder: What is the royalty?

The Chairman: That is according to the size of the machine.

A Shareholder: What is it per cent.?

The Chairman: I cannot give the percentage, but I can say that, with the percentage, the cost is certainly not more than two-thirds that of the Weston machine. It is a minimum, not a prohibitive royalty. The Company do what business they may—what terms they think fit, the profits to be divided equally between the Company and the patentees. I acted in the matter of the patents, because they did not need to go a begging. I made all the outlay, and the patents are at the disposal of the Company; the Company does not think fit to take the patents, the patentees are prepared to pay all the Company has expended in making machines. It has not been a question of throwing away money for nothing. In return to the question of the appointment of the committee, the committee were appointed to confer with the Board. It was distinctly understood it was not to be an investigation committee, it was

agreed it was to be a friendly committee to confer with the Board so as to improve the future position of the Company. Now, I think the future position of the Company is the question with which we are concerned. At the first interview I had the honour of holding with this committee, I had a paper put into my hands by a gentleman who was acting as chairman of that committee, desiring to see certain books and papers. I said: "Gentlemen, I take the entire charge of this Company, and, as the Secretary has only been about a year in the Company, and is not so conversant with the past as I am, I shall be glad if you will refer to me on any matters as I can give you more information than he can, and I will give you any reasonable information as long as the result of it will not be injurious to the interests of the Company. The chairman of the committee handed me this paper, and the books were immediately handed to him. On leaving the room I was told that they would let me know when they wished to see me again. I did not hear from them for weeks, but the next intimation was that they desired to see me at once. In the meantime, I do not know that I would have sanctioned the committee going to individual workmen and getting information to come here and give it to the public. A Voice: "Why not?" Simply because, sir, I am willing to give every shareholder privately whatever information he may require, but there are in this Company secretaries and officials of other electric companies, and I should certainly not be prepared to give to these gentlemen details with regard to the conduct of our business. I think that answers—Why not?

After a long rambling, and recriminatory discussion the report of the committee was adopted.

REUTER'S TELEGRAM COMPANY.

The ordinary general meeting of the shareholders in Reuter's Telegram Company, Limited, was held on Wednesday last, at the offices, Old Jewry.

Colonel J. Holland presided, and in moving the adoption of the report stated that the revenue of the past year had been larger by £1,300 than that of 1886, but the expenses showed an increase of £3,400. Hence the decrease in the dividend. In the past year there were several prolonged periods of excitement, entailing considerable outlay, which was not compensated for by extra subscriptions, as would have been the case in the event of actual war.

Admiral the Right Hon. Sir J. C. D. Hay, K.C.B., seconded the motion, which was carried unanimously, and the retiring Director and Auditor were subsequently re-elected.

PROVISIONAL PATENTS, 1888.

APRIL 13.

5493. Improvements in that class of lights known as "search lights," the same being applicable to other lights of an analogous kind. William Harvie, 115, St. Vincent street, Glasgow.

5522. Improvements in telephonic apparatus. Adolph Heinrich Gerthel Segnitz, of the firm of Reising Brothers and Co., 4, South street, Finsbury, London. Ehrhard Brand, Brazil.

5528. An improvement in plates for voltaic batteries. Eugene Heinitz, Edward James Paterson, and Charles Friend Cooper, 28 Southampton-buildings, London, W.C.

5529. Improved construction of reflector for use with incandescent electric lamps to facilitate its removal or readjustment. Peter Gregory Merry, 166, Fleet street, London.

5531. A new or improved system of electric lighting and apparatus therefor. John Grace Statter, Norfolk House, Norfolk-street, London, W.C.

APRIL 14.

5554. Improvements in apparatus for covering wire or conductors. Robert Wood, 1, St. James's-square, Manchester.

APRIL 16.

5640. Improved means to be used in supplying, distributing, controlling, and indicating electricity for lighting and other purposes. Henry Edmunds, 47, Lincoln's Inn Fields, London.

APRIL 17.

5691. Improvements in switches used for electrical purposes. Charles Scott Suell, Culver Park, Saltash, Cornwall.

5703. Improvements in switch-boards or apparatus for the distribution of electricity. John Smith Raworth, 46, Lincoln's Inn Fields, London, W.C.

5708. Improvements in dynamo-electric machines and motors. John Lea and Charles Julian, 75, Arlington-road, Camden Town, N.W.

5713. Improvements in electric elevators. John Keeser Hallock and George Canfield Blackensderfer, 77, Chancery-lane, London, W.C.

5723. The production of chalybeate waters by electrolytic action and apparatus therefor. William Weber, 28, Southampton-buildings, Chancery-lane, London, W.C.

5732. Improvements in, and relating to, apparatus for measuring electric currents, which apparatus will also serve as a motor. Harry Harris Lake, 45, Southampton buildings, London. (Elhu Thomson, United States.) (Complete specification.)

APRIL 18.

5745. An instrument for use in making electrical contacts. Syllax Hall Gillan, Othry Vicarage, near Bridgwater, Somersetshire.

5753. The Daisy long distance telephone and transmitter. Gerard Huck, 72, St. James' street, Barnley, Lancashire.

5764. Electro motor velocipedes. Charles Adams Randall, 7, Alfred street, Montpelier-square, West Bromwich, London.

5782. A new or improved electric arc lamp. William Charles Mountain, 2, Rothsay-villas, Eglington road, Wandsworth.

5783. Improvements in electrical transformers. William Charles Mountain, 2, Rothsay-villas, Eglington road, Wandsworth.

5790. Improvements in and relating to the preparation of non-metallic porous bodies for electro-metallurgical deposits. Hubert Steinach, 18, Buckingham street, Strand, London, W.C.

APRIL 19.

5811. Improvements in, and connected with, the generation and distribution of electrical power, chiefly by alternating currents. Rookes Evelyn Bell Crompton and James Samlunge, Air Works, Chelmsford.

5831. Improvements in means or apparatus for lifting, lowering, and regulating the height of the elements in electric batteries. Theodor Schlothe Schorer, 2, East-passage, Leeds, Yorkshire.

5843. An apparatus for performing operations at intervals, applicable to the making of electric contacts, or for analogous uses. Henry Edmunds, 47, Lincoln's Inn Fields, London.

COMPLETE SPECIFICATIONS ACCEPTED.

APRIL 28, 1887.

6204. Improvements in induction coils and transformers. Wm. John Miller, 70, Chancery-lane, London, W.C.

MAY 25, 1887.

7553. A method of regulating the electromotive force of dynamo-electric machines. Frederick George, Uley, Dursby, Gloucestershire.

JUNE 7, 1887.

8181. Improvements in means or instruments for testing submarine electric telegraph cables or for analogous purposes. Herbert Arnold Taylor, of the firm of Clark, Foulie and Taylor, 47, Lincoln's Inn Fields, London, W.C.

JUNE 16, 1887.

8708. Improvements in apparatus for fixing telegraph posts. Joseph Oppenheimer, Carlton Chambers, 18 St. Ann's street, Manchester.

AUGUST 10, 1887.

10,963. Improvements in instruments for the measurement of electromotive force and power. John Andrew Fleming and Charles Henry Gunningham, 47, Lincoln's Inn Fields, London.

FEBRUARY 20, 1888.

2515. Improvements relating to dynamo-electric generators and motors. James Featley, Grey's Inn Chambers, 20, High Holborn, London, W.C.

MARCH 15, 1888.

3995. Improvements in and relating to galvanic batteries. Henry Harris Lake, 45, Southampton-buildings, London. (Hugo Walter, United States.)

MARCH 20, 1888.

4274. Improvements in or relating to storage batteries. Wm. Phillips Thompson, 6, Lord-street, Liverpool. (Charles David Paige Gibson, United States.)

4275. Improvements in or relating to storage batteries. Wm. Phillips Thompson, 6, Lord-street, Liverpool. (Charles David Paige Gibson, United States.)

SPECIFICATIONS PUBLISHED.

1887.

4116. Electric incandescent lamps. A. F. St. George and C. R. Boune. 8d.

4706. Direct motor wheel for driving carriages, dynamos, &c. F. F. Lee. 8d.

5862. Simultaneously driving clocks by magneto electricity. W. Reinlein. 8d.

5958. Dynamo-electric, &c., machines. A. M. Clark. (Maiche.) 8d.

6754. Dynamo-electric machines. R. E. B. Crompton and J. Swadlow. 11d.

6917. Electric transformers induction coils. W. M. Morley and C. E. Webber. 8d.

6967. Electric arc lamps. A. Siemens. 8d.

7021. Electro-dynamic machines. G. Scarlett. 8d.

1888.

112. Incandescence lamp holders, &c. H. F. Joel. 6d.

506. Incandescent electric lamps. C. M. Dorman and H. A. Smith. 6d.

750. Electric railways. H. H. Lake. (Worms.)

CITY NOTES.

Brazilian Submarine Telegraph Company. The traffic receipts of the Brazilian Submarine Telegraph Company for the week ended April 20 amounted to £4 104.

St. James' and Pall Mall Electric Light Company. The letters of allotment in the St. James' and Pall Mall Electric Light Company have been posted. Mr. James Hemmende has joined the board of the Company.

United Telephone Company. At a meeting of the Board of Directors of the United Telephone Company, held on Tuesday last, Mr. Frederick Richards Layland was elected a Director of the Company, in the room of the late Mr. E. Dwyer Gray, M.P.

The Cable Companies' Dispute. A telegram from Paris says: "The court has reserved its decision as to the pending differences between the Anglo-American and French Cable Companies until the proper courts have decided with regard to the step taken by the Government respecting the French company, which was the origin of the lawsuit."

Eastern Extension, Australasia, and China Telegraph Company. The Eastern Extension, Australasia, and China Telegraph Company announce that the coupon on their Five per Cent. Debentures 1880 issued, due on May 1 proximo, will be payable on and after that date, on presentation of the same at the Consolidated Bank, 52, Threadneedle street, E.C. Coupons should be left three clear days for examination.

Renter's Telegram Company. The report of Renter's Telegram Company, Limited states that the net profits for the year ending the 31st December amounted to £4,242, including £187 brought forward. An interim dividend of 2 1/2 per cent. was paid in October, and they now declare a further dividend of 2 1/2 per cent., making a total distribution, tax free, of 5 per cent. for the year. After adding £500 to the reserve fund, £61 will be carried forward.

West India and Panama Telegraph Company. The Directors of the West India and Panama Telegraph Company, Limited, owing to improvements of revenue derived from exceptional causes and some increase in the traffic, recommend a dividend of 10s. per share on account of arrears of dividend on the 1st preference shares. The estimated traffic receipts of the Company for the half month ending the 15th April are £2,022, as compared with £2,373 last year, showing an increase of £649.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company for the week ended April 20 after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,390. The Directors of the Company in their report for the year ended December 31, state that the net earnings amounted to £159,789 an increase of £21 123. The working expenses, exclusive of renewals of cable, were £64 516, as against £62,604. Including the amount brought forward, the revenue balance is £100 032, from which has to be deducted £27,000 for debenture interest leaving £73 032, of which £15,000 has been placed to the renewal fund, and £10,000 to a debenture redemption fund. The Directors recommended a dividend of 3 per cent. tax free, which with the interim dividend of 1 1/2 per cent. paid on the 15th of October, makes a total of 4 1/2 per cent. leaving £3,464 to be carried forward. This will give to the preferred ordinary shares 5 per cent. for the year, will clear of £3 14s. the amount in arrears upon these shares, and give 2s. 1 1/2 per share to the deferred ordinary shares. The undertakings of the Company and of the London Platino-Brazilian Company, Limited, are so closely allied that it has become desirable, in the opinion of the Board, that, so far as may be practical, without effecting an actual amalgamation as to which at present difficulties stand in the way, they should be brought under a common control, with a common property, and, after long negotiations, arrangements have been made for this purpose. An agreement has, it is stated, been entered into by the Board of each company for the exchange of the shareholders of the Platino Company of their shares for shares of the Company at the rate of five shares of £10 of the Platino Company for three shares of £15 of the Company, and for the substitution of Directors and officers of the Company for those of the Platino Company, who will receive compensation as provided in the agreement. The capital which may be required for these purposes will not exceed 24,000 shares. The agreement, subject to such modifications as the special resolutions of each company, and conditional upon three-fourths of at least of the shareholders of the Platino Company exchanging their shares within fourteen days after such confirmation, or such extended period as may be agreed on, will be submitted for approval to the ordinary general meeting and, if approved, a further resolution may be proposed, authorising the increase of the capital to £1,500,000 for the purpose of enabling its fulfilment and for other purposes.

Bournemouth.—The question of giving sanction to the application of Messrs. Phillips, Harrison, and Hart to the Board of Trade for a license to supply electricity within the district came up again for consideration. The subject was adjourned from the last Board meeting. The Clerk said that since the last meeting of the Board he had received a draft of the proposed license. The document was of considerable size, and should be carefully considered in committee. He suggested that it be referred to a committee of the whole Board, and that the discussion of the question be further adjourned until the next Board meeting, and it was so adjourned.

The Cance Arc Lamp.—The new low-power lamps by the above-mentioned maker, taking from three to six amperes, and giving, when enclosed within ground glass globes, a light of from 120 to about 240 candles, have attracted much attention at the exhibition of the French Physical Society. The light is as steady in the case of these small arcs as in the lamps taking seven or eight amperes, and the question of the distribution of the arc light thus appears to be very satisfactorily solved. As a contrast to these small lamps, M. Cance has just constructed two lamps taking from thirty to forty amperes, these vast sources of light being for the Bon Marché establishment.

Winterthur.—Progress is being made in various directions in electric lighting. The steamers "Helvetia" and "Thurgau" have been fitted with the electric light, and the North-Eastern Railways intend adopting it for all their steamers on the Lake of Constance. At the Hotel Engadiner Kulm at St. Moritz, 10 arc and about 700 glow lamps are installed. This lighting can be greatly extended, as only half of the water-power of 180 h.p. available is at present utilised. A scheme is also on foot for lighting the town of Interlaken electrically, and a commencement will be made by the erection of arc lamps in the Hoheweges and the large hotel situated there.—*Industries.*

Accumulators.—Prof. Tito Martini publishes in a pamphlet of 10 pages, which he read to the Royal Institute of Science, Literature, and Art at Venice, his report on the various trials which he made with the accumulators of Montaud, Cannstatt (Fabrik), Sellon-Volkmar, and Trevisian. The result of these trials was that the accumulators of Sellon-Volkmar, as supplied by the E.P.S., and those of Trevisian are much to be preferred to the other two types. It is specially noted of the Sellon-Volkmar type that it maintained its good reputation in every respect, and the Professor also speaks very highly of the less known make of his countryman, and specially reports that this type distinguishes itself especially by the long life of the positive plates.

"Journal" of the Society. The new part of the *Journal* of the Society of Telegraph Engineers has just been issued, and contains the paper by Mr. R. von Fischer Treuenfeld upon the "Present State of Fire Telegraphy," and the discussion thereon; also the paper by Prof. Rucker, F.R.S., and C. V. Boys, A.R.S.M., "On the Optical Demonstration of Electrical Stress." We cannot help referring to a sentence of Prof. S. P. Thompson during the discussion on this latter paper, in which he refers to that excellent little book, by Mr. F. C. Webb, on "Electric Accumulation and Conduction." In our opinion this book ought to be re-edited and republished. It was not appreciated when originally written, because so much

before its time, and had but a limited circulation. But to return to the *Journal*. The number concludes with a list of additions to the library, the society's balance-sheet, and the abstracts of foreign papers.

Isolated Electric Lighting in Towns.—Legal proceedings have been instituted against the managers of the Vandeville Theatre and the Café Americain, in Paris, by the inhabitants of the houses adjacent to these two establishments. They complain not only that the court-yards of neighbouring houses are filled with smoke and blacks arising from the engines used to drive the dynamo machines, but also of the vibration produced by the engines in question. The object of the proceedings was to obtain the appointment of an expert to consider and to carry into effect the work necessary for abating the nuisance. This object, we are informed, has been attained in the appointment by the president of the referees of an electrical engineer, M. Fribourg, as the expert in question.

Electric Cricket Club.—At the annual dinner of the Cardiff Electric Cricket Club, Mr. Gavey, in responding to the toast of "The Service," spoke of the advancement and improvement in telegraphy generally, and especially in Cardiff. That town was rapidly growing, but the telegraphic service kept well in advance. As an instance of its progress, he said that two trunk lines were now to be laid down in order to connect Cardiff for the first time with Glasgow and Manchester, so that by the middle of next summer Cardiff would be in direct communication with the most important of the large manufacturing and commercial centres, and thus occupy as good a position as any town in the country. The toast of "The Electric Cricket Club" was given by Mr. S. Jones, and the captain (Mr. H. Evans) and secretary (Mr. Baxter) responded. Other toasts, songs, recitations, &c., followed, and a convivial evening was spent. Why—oh, why? Mr. Albright, Mr. Stepney Rawson, and other athletic electricians, do we not get up a peripatetic cricket club for the London district.

Obituary.—Many members of the Society of Telegraph Engineers wondered at the last meeting to hear so high an eulogium from Capt. Douglas Galton upon one whom all who knew him regret to have lost, but whose name was not so familiar to the younger generation of electricians as it was to those who were pioneers in submarine telegraphy. The late T. R. Crampton was a friend of the old school, whose hand clasp was as warm as his heart was large. He was a genial companion, and cared more for honest friendship than for the fickle praise of sycophants. To his energy and ability the success of the cable from England to France was greatly due. The writer has often chatted with the veteran over those old days, information about which is so frequently incorrect. But Mr. Crampton made a name in directions other than telegraphy, and is better known to the world, perhaps, in connection with his railway work than in any other. His presence will be greatly missed by a select circle which used to be merry at each return of the meeting of the British Association.

Traction in Mills.—At the Tremont and Suffolk Mills, Lowell, Mass., an installation of Thomson-Houston electric motor cars, for hauling the bales of cotton, &c., has been working very successfully for some months. The motor is mounted on a specially constructed car, the current being conducted by a single overhead line, returning by the rails. The motor will draw four tons; the rails are 14 ft. 8½ in. gauge and extend for 800 ft., running the full length of two buildings and up an incline across a bridge. It is furnished with a

reversing switch, speed regulator, and brake handle, and has acted with so much satisfaction that the mill owners contemplate considerable extension, and the Thomson-Houston Electric Company are understood to be preparing for considerable work in this direction. For large mills, with their long lines of flooring, a small platform car, running throughout their length on narrow gauge rails to distribute or gather the material, is capable of very general adoption, and it is said by the mill-owners to be one of the most convenient mechanical arrangements they have about their whole mill.

Indian Telegraph Service.—Mr. Conybeare asked the Under-Secretary of State for India, on Tuesday, what had been the result of the special inducements to retire offered to the officers in the blocked years of the Indian Telegraph service; whether such inducements had had the desired effect, and, if not, what was the cause of failure; whether it was the fact that promotions in the telegraph service were now made only twice a year; whether the effect of this arrangement was to inflict a loss of, perhaps, several months' pay and promotion in the case of those who were moved up into vacancies in the intervals between the biennial promotion days; and whether such a rule was in force in any other branch of the public service. Sir J. Gorst answered that the first period at which retirement might have taken place was March 31. No intimation as to the result has yet been received. Permanent promotions are now only made twice a year, but acting promotions are made as vacancies occur. The full pay of the higher rank is not attained until the permanent appointment is made. Meantime an acting allowance is received. No such rule is in force in other departments of the public service.

Transmission of Energy in Spain.—A company in Valencia has obtained a concession for the distribution over a distance of 35 miles of motive power, to the extent of 3,000 to 4,000 h.p., which is to supply the requirements of the town and its neighbourhood. The company in question is in negotiation with several English firms relative to the execution of this undertaking. The Turia river, from which power is initially to be obtained, supplies about 10 cubic metres of water per sec., and has a fall of 32.4 metres at the point where the supply is to be utilised. The expense of developing the motive power is estimated as follows:—

Interest at 5 per cent. on an initial capital of 3,327,800fr.	166,387fr.
Amortisation in 20 years of flood gates, sluices, &c. say 5 per cent. on 176,675fr.	8,850 „
Amortisation in 20 years of the electrical apparatus say 5 per cent. on 810,350fr.	42,025 „
Amortisation in 50 years of the electric line and its accessories—say 2 per cent. on 960,950fr.	19,225 „
Maintenance of hydraulic machines (1) Memoir	
Maintenance of electrical apparatus at the rate 2 per cent. on 1,801,325fr.	36,026fr.
Total.....	277,826fr.

Rouen. This capital of the Seine Inferieure appears to be leaving the capital of France far in the background. Besides the work done by its central lighting station, several considerable installations have recently been carried out. A waterfall situated about 1,500 metres from the works of M. Giron has been utilised for the production of electric power; and the Thomson-Houston Company have installed nine arc lamps, each of 1,200 c.p., at these works. A current from the same source illuminates several large

greenhouses belonging to M. P. Richard, horticulturist, at Rouen; and the effect of the light upon vegetation is therein being investigated by the Rouen Horticultural Society, who intend to issue a report on this question. The office of the *Patriote de Normandie* is being fitted with 35 incandescence lamps, supplied by a small Thomson-Houston machine, worked by a gas motor; the lighting being safeguarded by means of an accumulator. Negotiations are in progress with reference to the lighting of the church of St. Ouen, on the Place de l'Hotel de Ville, by means of 100 arc and 350 incandescence lamps; the motive power being supplied by steam engines at a distance of three kilometres from the church. Applications have been made to the Municipal Council for authority to light the theatre and several public establishments.

The Ader Signalling System.—According to the *Bulletin de l'Electricité*, the experiments made on the system of signalling by means of telephones through long submarine cables justify the expectation that the speed of signalling through such cables may be increased by this means. This would of course render M. Ader's invention of practical importance—perhaps of very considerable importance in submarine telegraphy. The system in question is very simple, and is at least of interest from an abstract point of view. At the receiving station the cable divides into two branches, each of which passes to earth through a telephone and a local battery. The two batteries have opposite poles connected to the cable, and are of such strength that one or the other of them nearly neutralises an arrival current in a given direction, whilst reinforcing an arrival current in the opposite direction. By means of an interruptor connected to each telephone, the instruments are caused to emit a different note when traversed by a current. Thus a positive arrival current sounds the note *sol*, for instance, in one of the telephones; whilst the other remains mute or nearly so, whilst a negative arrival current will sound *do* in the other instrument. The system is probably already familiar to many of our readers; but to others it may be rendered intelligible by the above brief description.

Telegraph Clerks.—Viscount Curzon on Monday asked the Postmaster-General whether in October and February last clerks at the Central Telegraph Station were promoted from the second to the first class three years before they reached the maximum of their class; whether clerks of from 17 to 19 years' service had been waiting at the maximum of the first class for 13 months; and whether there was anything against the ability or character of these clerks, and, if not, why this partiality was shown to one class. In reply, it was stated that the facts set forth in the question were substantially correct. In the one case there were vacancies at the time on the higher class, whereas in the present case there are no vacancies, and consequently no promotions can be made. In answer to Mr. Carew, Mr. Raikes also said: On the acquisition of the telegraphs by the State, the reason for subjecting the telegraphists at the Central Station to a deduction during absence from illness was that they might not be subject to different rules from those which applied to Post Office servants of similar grade. These rules have been considered again and again, and I am not prepared to alter them. Full pay during absence is confined, as a rule, to those who occupy the more responsible positions. The officers of the intelligence branch are picked men, selected from the whole body of telegraphists throughout the kingdom.

The Electric Light in Italy.—In the report presented by the Administrative Council to the general meeting of the Edison Company in Milan, the increase of joint stock enterprise is pointed out. At the end of last December the installations already carried out comprised 11,010 incandescence and 218 arc lamps—that is to say, 1,470 incandescence and 64 arc lamps over and above the number that had been installed in December, 1886. The receipts amounted to 564,622.27 liras, showing an increase of 161,728.84 liras over the preceding year, whilst, on the other hand, the expenses have increased during the same period only by 63,307.28 liras. The number of isolated installations has very much increased, the most important of these carried out in 1887 being those of the San Carlo and Sannazzaro theatres of Naples. The result of the proceedings of the gas companies against the Municipality of Milan has given a fresh stimulus to the electrical industry. For the information of some of our readers, we may state that this result was that the court rejected the application of the gas company, and authorised the municipality to install electric lighting in the streets. It is true that competition on the part of gas is still prevalent; but this judicial decision has had the effect of reducing it. Moreover, there is plenty of room in Milan to allow of the two systems subsisting together side by side.

Shakespeare and Electricity. The same year which saw the publication of Gilbert's work on electricity witnessed also the appearance of Shakespeare's plays of "Hamlet" and "Much Ado About Nothing." That Shakespeare had considerable knowledge of atmospheric phenomena now, but of course not then, known to be electrical, is apparent from many instances. Witness Prospero's

"to the dread rattling thunder
Have I given fire and I rife I Jove's stout oak
With his own bolt."

Or Ariel's self description in the guise of St. Elmo's fire:

"Sometimes I'd divide
And burn in many places: on the topmast,
The yards, and bowsprit would I flame distinctly,
Then meet and join."

There are but two passages, so far as I have been able to discover, in which the poet makes reference to the attraction of iron. The first is in "Midsummer Night's Dream" (act ii, scene 2):

"You draw me, you hard-hearted adamant,
But yet you draw not iron, for my heart
Is true as steel. Leave you your power to draw,
And I shall have no power to follow you."

The second is in "Troilus and Cressida" (act iii, scene 2):

"..... truth tird with iteration
As true as steel, as plantage to the moon,
As sun to day, as turtle to her mate,
As iron to adamant."

Park Benjamin in April "Forum."

Writing Telegraphs.—In the House of Commons the other day Mr. M Ewan asked whether the Postmaster-General's refusal to grant a licence to the proprietors of the Writing Telegraph was indicative of a resolution to depart from the position taken up by the Government, as defined by Sir Henry James (then Attorney General) on the 15th of December, 1880, in the case of "The Attorney-General v. United Telephone Company," as follows:—"There is no desire on the part of the Crown to check invention. I most emphatically disclaim that. Inventors and companies will always be dealt with in a liberal spirit if they consent to become licensees of the Crown; and, seeing that the proprietors of the Writing Telegraph only wished to become licensees of the Crown, why should they be treated differently from other companies using telegraph systems?"

Sir H. Maxwell replied that the Postmaster-General had not succeeded in finding a record of the statement attributed to the right hon. member for Bury. The arguments in the case of "The Attorney-General v. the Edison Telephone Company" (it was not the United Telephone Company) were concluded on the 3rd of December, 1880. Judgment was given on the 20th, and there were no proceedings in Court on the 15th. In the absence of more specific information, therefore, he was not able to follow the hon. member in his reference. He observed, however, that the Telegraph Act of 1869 leaves it to the Postmaster-General's discretion whether a licence shall or shall not be granted to a person or company proposing to transmit telegrams, and the Government have never assumed the position of granting indiscriminately a licence to every inventor of a new form of apparatus.

Hamburg.—The electric light installation of the Free Port and Docks of Hamburg will comprise, when finished, 50 arc lamps of 10 amperes, and about 4,000 16 candle-power incandescent lamps. The arc lamps are grouped in series of 10, and each circuit is fed by its own dynamo. The incandescent lamps are in multiple, and divided into a number of circuits, the current for which can be arranged from the switch board in the dynamo room. The motive power for the incandescent circuit is obtained by three pairs of compound engines, each of 220 horse-power nominal. Two of these engines are already in place, the high pressure cylinder is 40 centimetres in diameter with 80 stroke, and the low pressure 60 centimetres in diameter with the same stroke. The engines run at 100 revolutions per minute. There will be six dynamos for the arc lamps—five usually working and one held in reserve driven by a single cylinder non-condensing engine, with a cylinder 362mm. in diameter, and having 724mm. stroke. The engine will make 90 revolutions per minute. The leads will be carried in rectangular iron pipe conduits underground. The power is transmitted from the engine by means of belts and countershafts. Six 8-pole Schuckert machines, making 350 revolutions per minute, will furnish a maximum current of 400 amperes under a pressure of 120 volts for the incandescent lighting. The current from the machine is laid to a distributing board; an ammeter is placed in the circuit of each dynamo and in each external circuit, of which there are eight actually laid. The voltage is regulated by an automatic regulator, and the state of the lamps at various points of the circuit is shown by guide lamps in the engine-room, fed by means of wires brought back from selected points of the principal circuits. When the machines are coupled in parallel, a resistance is used to obtain the same voltage at the terminals of the machine. The pressure at the lamp terminals is obtained by interposing more or less resistance in the service mains. This operation is effected automatically by means of electro-magnets and resistance coils in each of the principal circuits. The commutator of this resistance coil is composed of a cylinder with metallic bars of unequal length, which automatically make contact, and thus interpose in the circuit a greater or less number of coils of German silver. In addition to the ammeters, voltmeters are also used, and the total consumption is registered by Aron-Coloumb meters.

Southampton.—It appears likely that Southampton will shortly have an opportunity of testing the capabilities of electricity; at present in the shape of the electric light, though, having regard to the wide field for operation in the town, it is not improbable that the current will, in the

future, be adopted for other purposes than that of lighting. In the first place, we have the Southampton Electric Light and Power Company, which has been registered with a capital of £30,000 in £5 shares, "to carry on the business of electricians, mechanical engineers and manufacturers, and workers and dealers in electricity, motive power, and light." It is proposed to start with 1,000 glow lamps and plant sufficient to work them. These lamps will be chiefly used in the shops and other places of business in the district surrounding the central station. The system to be used and the method of distribution have yet to be decided on. The station will be situated in the High-street, on premises in an excellent position for the purpose, and containing ample accommodation for the plant both for the present work and for future extensions. The first subscribers to the Company are all residents in or near the town, and are intimately connected with it. The undertaking is favourably regarded by many of the leading tradesmen; and with all these things in its favour the Company should be a success. At a meeting of the Town Council on the 25th ult., the Special and General Works Committee reported that they had again considered the report of the borough surveyor (Mr. Bennett) as to the cost of lighting by electricity the Audit House, the Guildhall, and the Hartley Institution, as well as the Corporation Wharf at Chapel, and certain streets in its neighbourhood, and recommended the adoption of the report. It is intended to utilise the heat from the refuse destructor at the Corporation Wharf for generating the current. The dynamos will charge a set of accumulators, and from these the lamps will be lit. The present cost of lighting the above-named places by gas, including the church clock of Holyrood, and a Sugg's lamp near the church, is £378. 10s., whilst the electric light is estimated to cost £207. 10s., thus showing a balance of £171 in favour of electricity. This large saving is due to the fact that there is no cost for fuel, as the burning refuse in the destructor supplies the heat. The estimated cost of the work is £1,440, for which it is intended to invite tenders. It is thus probable that Southampton folks may shortly be in a position to appreciate the value of electric lighting.

Price of Gas.—It is often interesting to electrical engineers to know the price of gas in any district. The following table (taken from an Aberdeen paper) gives such prices, and the number of consumers for various towns:

Popu- lation.	Town.	Illumi- nating power in candles.	Price per 1000 cubic feet. a. d.	No. of con- sumers.
30,000	Aberdeen	15	4 3	744
12,300	Altrincham	19	3 3	2,300
22,000	Arbroath	27	4 1½	5,041
37,000	Ashton-under-Lyne	19	2 4	8,668
31,500	Barnsley	18	2 6	3,900
50,000	Barrow-in-Furness	20	3 6	2,466
30,000	Batley	17	3 0	5,200

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, B.SC., F.R.S.E.

[All rights reserved.]

(Continued from page 296.)

THE MEASUREMENT OF LOW RESISTANCES.

The measurement of the resistance of conductors used for the mains or principal branches of electric light leads, the armature coils of low-resistance dynamos, and other purposes of a similar kind, has become of considerable importance, and I propose to consider one or two of the most convenient methods of proceeding. When the resistance is not very low, the measurement may be made with sufficient accuracy by means of a box of conductances such as that shown in Fig. 7, p. 199 above. The conductance box is in this case used as one side of the Wheatstone's bridge, the wire under test forming another, while the other two sides, or the divided resistance, as it is often called, may very conveniently be the wire of one of the forms of Kirchhoff bridge already figured and described (Figs. 11 and 12, p. 247). The greatest difficulty, perhaps, in the application of this method is in the elimination of the resistance of the contacts and the wires required to connect the test piece, or coil, into the bridge. Take, for example, the armature of a dynamo. It is impossible to put the commutator, or brush rings, directly into the binding screws or mercury cups of the bridge, and hence connecting wires have to be used. Now, the resistance of these, even when so thick as to be inconvenient for handling, may be equal to quite a large fraction of that of the coil being tested, and hence a second test of the resistance of these connections is required in order to eliminate them from the result. There is, besides, a liability to large percentage errors, due to resistance in the multiplicity of contacts introduced. In such cases one or other of the following methods will be found preferable:—

1. *Series Circuit Potential Method.* In this method the test piece, or coil, the resistance of which is required, is joined in series with a standard bar of suitable resistance in the manner shown in Fig. 18. Referring to this figure,

FIG. 18.

w represents the standard bar, which we will suppose mounted on a board on which there are also fixed a mercury trough, C , and a reversing key, K . The key, K , may be of any convenient form, but for the testing of specimens of thick conductors it is convenient to make it of four cups of mercury arranged at the four corners of a square, the ends of the wires, w and w_1 , being placed in the cups at the opposite ends of one diagonal of the square, and the two electrodes of the battery in the cups at the ends of the other diagonal. The current can then be sent through the circuit in either direction by means of two copper U's of width equal to the side of the square. The standards, w , should either be of uniform resistance along their length, or they should be calibrated and provided with a scale, so that the resistance between any two points of their length can be readily calculated. Suppose, in the first place, that the resistance per yard or per metre of a thick copper conductor is to be measured. Put one end of a specimen of the conductor into the mercury cup, C , and connect the other end to one of the terminals or mercury cups of the key, K . Close the circuit through the battery, B , putting a resistance in the battery electrodes, should the current be too strong for the battery to maintain steadily. Now place the terminals of the electrodes of a sensitive galvanometer, G , of moderate resistance, in contact with two points a and b , and note the deflection produced. Next find two points c and d on the standard bar, at which, when the terminals of G are put in contact with the bar,

the same deflection is produced. If there is no thermo-electric effect on the galvanometer due, for example, to difference of temperature and difference of thermo-electric quality of the conductor between the points a and b or c and d , the resistance of the part of the conductor between the points a and b will be equal to the resistance of the part of the standard bar included between c and d . This conclusion follows at once from Ohm's law and the fact that the same current is flowing in both conductors. In order to avoid chances of error due to thermo-electric effect, the current should be reversed and the experiment repeated. The arithmetic mean of the results will give the true length of the standard bar which is equivalent to the length $a b$ of the conductor under test. From the length of the conductor between a and b , and the known resistance of the standard bar, the resistance per unit length of the conductor can be calculated from the equation: Resistance

$$\text{per unit length} = \frac{\text{Resistance of } cd}{\text{length of } a b}.$$

The galvanometer used for this test must have considerable sensibility, because with even a strong current flowing through a thick rod of copper only a yard or two long, the difference of potential between the points a and b will be small. A mirror galvanometer is most suitable, but any galvanometer having the requisite sensibility will do; it should have such a resistance that the current flowing through it is a small fraction of the current in the circuit. It should be observed, however, that this does not, as a rule, imply that the galvanometer should be a high resistance one in the ordinary sense. Quite the contrary is the case, as a high resistance galvanometer is never sensitive to small E.M.F. at its terminals, and a galvanometer of one ohm, or even a tenth of an ohm, resistance, will not, when used in this way, take a sensible fraction of the current flowing through a copper conductor of half a square inch, or more, cross section. There is, of course, no error introduced, even if the galvanometer takes a sensible fraction of the whole current, if equal deflections are obtained for the resistance between $a b$ and $c d$, because, in that case, the shunting action of the galvanometer is equal for both deflections. If, however, different deflections are used, and the length of the standard which is equivalent to $a b$ estimated from the relative deflections, the relative currents in the main and the galvanometer circuits must be known when the galvanometer current is strong. When a sensitive galvanometer is used, there is generally a slight change of zero when its terminals are joined. The reading obtained when the ends of the electrodes are in contact should be taken as the zero of deflection.

An important modification of this method will, no doubt, occur to most readers that is, the use of a differential galvanometer instead of G . This has the great advantage of making the method a zero deflection one, and this in almost all cases conduces to accuracy and increase of sensibility. When a differential galvanometer of suitable resistance is available, the electrodes of one coil are placed in contact with two points, a and b , and the electrodes of the other coil are then adjusted to two points, c and d , such that no deflection is produced. In the use of this method the coils of the galvanometer should not be arranged to have a common terminal, because in that case part of the circuit would be shunted through that terminal, and the result would be disturbed by contact resistances.

As another example, we may consider the case of the measurement of the resistance of the coils of a dynamo armature. Take a Gramme ring for example. Place the board carrying the standard rod, w , the key, K , and the mercury trough, C , in a convenient position near the dynamo, and carry thick connecting pieces from the dynamo terminals to K and C . Pass a current from a battery through the circuit, and find the deflection on the galvanometer, G , produced by putting its terminals in contact with the same commutator bars that are touched by the brushes. Next find the equivalent length of the standard bar as before. The experiment is in this case precisely similar to the already fully described, with the exception that connecting wires have to be introduced from the dynamo terminals to the testing board. The resistance of these leading wires in no way enters into the test, and hence no inconvenience is introduced by their use. It should be particularly noticed

contacts of the galvanometer terminals are to be direct to the commutator bars, and not to the brushes, the resistance of the brush contacts do not enter. Application of this method to the investigation of the effect of motion on the contact resistance of brushes is and will be referred to further on.

Parallel Circuit Potential Method. A very convenient method for tests such as we are now considering, as several other tests which we will have to consider shown in Fig. 19. A heavy copper bar, A, furnished with a terminal screw, or a mercury cup, T, forms the terminal of a set of conductances, which are here in the form of spirals of wire. These conductances in any form which is convenient in the circuit, and where the size of the apparatus is a matter of indifference, perhaps the best form is simply a set of straight platinoïd, say, an eighth of an inch in diameter and $\frac{1}{2}$ inch long, soldered to the bar, A, at one end, and fitted at the other end into a deep copper trough, C. These conductances should be equal, both in dimensions and in conductance, so when any number of them are joined in parallel, the same current will flow through each, even if the resistance is so strong as to heat them considerably. A mercury cup, D, and cup, E, are arranged on the same board with A, in such a position that the terminals of all the conductances can be placed in C, while the terminal of that one is placed into D. The trough, C, and the cup, D, should be made of copper, or have copper bottoms, which, the thickness of C, must be so thick that its conductance is a thousand times that of one of the platinoïd rods. At the other end of the board two copper blocks, in which are fixed the cups E and F, are fixed. To the former, a wire (w_1) is fixed, and the latter is in metallic

FIG. 19

with the lever H, which slides along w_1 . When the apparatus is in use for the determination of the conductance of specimens of conductors, the coils of dynamo, the secondary coils of transformers, &c., the specimen is placed in the position shown by w_1 , between C and the standard conductance, w_2 , between D and E. The low resistance battery is then joined between F and a sensitive galvanoscope, g , between C and D. The conductance is then introduced between A and C, and such a number of the others between A and C, turning the lever H into contact with some part of w_1 , the current through g can be reduced to zero. In this case, the current through the standard is in the same ratio as unity is to the number of conductances between A and C. The current through g is kept at zero by adjusting the position of the lever H, if necessary, and two pairs of points, a and b , and c and d , on w_1 and w_2 , found by means of another galvanoscope, are at the same potential. The conductance of the rod w_1 , between the points a and c is then the conductance of the standard between c and d , divided by the number of conductances introduced in parallel between A and C. This method has the advantage of a zero method, and, also, that standards of moderate resistance can be used for the measurement of the conductance of very thick conductors; and when the conductance between A and C are carefully adjusted to equality, a high degree of accuracy is obtained. It is evident that any coil or circuit may be

put in place of w_1 , the connecting wires being put to C and F, while a and c are taken at the ends or any other part of the circuit. The same remarks that were made with regard to method (1) as to the applicability of a differential galvanometer in place of G apply in this case, but since the method is itself a zero one, the advantage is not very great. When a differential galvanometer is used, the two ends of one coil may either be put in contact with two points on one wire, and the terminals of the other coil adjusted on the other wire, until no deflection is obtained, or the terminals of one coil may be put to a and b , and those of the other coil to c and d , in which case it is immaterial whether the effect on each coil is zero, or the resultant on both is zero, providing, in the latter case, the proper terminals are put in contact with w and w_1 . In order to avoid error due to thermo-electric potential in the circuit, the experiment should, as in method (1), be repeated with the direction of the current reversed. The degree of accuracy with which, when proper appliances are available, the measurement of the conductance of thick rods or tubes can be made by the methods just described, depends mainly on accuracy with which the lengths a and b and c and d can be determined. The conductance of even a foot of copper rod a square inch or more in cross section may be measured with almost perfect accuracy. The subject will be further considered in a continuation of this article.

ELECTRIC LIGHTING.

Proposed conditions under which electric light wires may be laid in the streets of Paris:—

CHAP. I.

ESTABLISHMENT AND MAINTENANCE OF DISTRIBUTING SYSTEM.

Object of the Conditions of Contract.

ART. 1. M. —, living at — (or the company, the offices of which are at —), is authorised to lay under ground, under the roads or the footpaths in the thoroughfares indicated in the annexed table, the wires or cables intended for the transmission of electric currents for the production of light, or for the transmission of motive power, and to execute, under the superintendence of the Administration, all the works necessary for distribution.

Installation of Wires or Cables.

ART. 2. The wires or cables may not be placed in the drainage galleries or underground ways beneath Paris.

They shall be laid beneath the footways in conduits of earthenware, of masonry, of metal, or any substance possessed of sufficient strength, and authorised by the Municipal Council after instructions from the Administration.

The position, the depth, and the maximum external diameter of these conduits shall in each case be fixed by the Administration, which will take into account, in arriving at its determination, not only the distributions already laid out beneath the same footway, but also, and more especially, those which it might reserve for establishment by itself in future for municipal purposes, it being understood that electrical distribution for the municipal service shall be the nearest to the surface of the ground. The licensee will not be permitted to bring forward any complaint by reason of a refusal to authorise the passage through certain streets on account of want of space beneath the footpaths under the conditions pointed out below, or on account of municipal reservations.

The wires or cables shall be placed under the roadways only for the purpose of crossings. These crossings shall be effected at a depth of at least one metre.

A distributing-main shall be established under each footpath adjacent to the premises to be supplied, so that the house branches may never cross the roads.

The only exception to this rule shall be for ways of which the breadth is considered by the Municipal Council to be insufficient.

Examination-boxes shall be established at certain distances, to allow of the inspection of the mains; and these shall be so arranged that, in case of breakdown, it shall be

possible, by utilising the examination boxes, to withdraw and to replace the wires without opening the roads. The localisation and the arrangement of these examination-boxes shall in other respects be established by the Administration. In all cases they are to be closed with bituminised covers.

The examination-boxes shall be obligatory at one of the extremities of each of the crossings under the roadway of the cables. In the case of crossings beneath broad or frequented ways, and particularly when the roadway has a foundation of concrete, an examination-box must be established at each end of the crossings, and the Administration may, in addition, provide that these examination-boxes should be connected by galleries of a type to be indicated by the committee, which galleries shall in no case be in communication with the drains or with the private branches therefrom.

If a drain should be in the way of a gallery, the cable is to be taken over the drain.

In the case where several companies might be authorised to establish conductors beneath the same footway, the cables of these different companies may be placed in a common conduit constructed at a common expense, and of which the dimensions and mode of establishment must be approved by the Municipal Council.

Reservation relative to the Installation of Wires or Cables.

ART. 3. The wires or the cables may be laid only at a minimum distance of one metre from the frontages of the houses, the position there within being reserved for the municipal electrical network, and when the Administration, after the consideration of the matter by the Municipal Council, shall have ascertained

1. That the position is suitable.
2. That the wires or cables, taking into account the strength of the current and the arrangement of the insulating envelope, may be placed there without danger to individuals and without inconvenience to the public service.

The reservation of one metre mentioned above, may be reduced by the Municipal Council in the case of ways in which it has been ascertained that the breadth of the footway is insufficient.

The Administration reserves in all cases the right to cause the licensee to remove his system of mains at a given period, either by reason of inconvenience caused by it, or simply in order to allow of new installations for the public service.

In default of the licensee carrying out this removal within the period allowed, he is liable to a fine of 50f. per day over time and per kilometre, or fraction of a kilometre, of main not so removed, without prejudice to the carrying out of the removal by the Administration itself. The licensee will be authorized in such cases to restore his system of mains under conditions to be laid down by the Administration, with the approval of the Municipal Council, as in all cases when a modification of the system of mains may be in question.

House Branches.

ART. 4. The wires leading into premises shall, between the principal cable and the frontage, be laid in conduits in connection with those of the main cable.

All portions of the installation other than the branch wires, such as cut-outs, &c., shall be established beyond the limits of the public way.

Transformers.

ART. 5. If the use be made of transformers, these are to be installed outside the public way.

Description of the Purposes of Distribution.

ART. 6. Prior to the commencement of the carrying out of any portion of the distributing system in the public ways, the plans upon which it is based shall be laid before the Municipal Council and the Administration, five copies of such plans being supplied by the licensee, who is not authorised to commence the work until after the notification of the reception of these plans. In drawing up the latter, one may have access at the offices of the engineers to all the materials at the disposal of the Administration in

relation to the conduits for water, and gas, or any other distributing system already authorised, of the drains and the private branches therefrom, of the existing or projected levels, &c.; but in no case can he have recourse against the Administration by reason of mistakes, imperfections, or omissions in the documents placed at his disposal, nor by reason of material obstacles which may happen in carrying out the work.

Access to Plans of Distribution.

ART. 7. The licensee will always keep open to access a plan on the scale of $\frac{1}{1000}$ of the network of distribution. Each house-branch shall thereon be indicated, with the number and the description of the lamps maintained in action, or a statement in horse-power of the motive power conveyed. This plan shall be supplemented by every information as to the destination and the constitution of the cables, the nature, the dimensions, and the position of the conduits, &c. Detailed sections, on a scale of from '02 to '05, are to indicate any special arrangements adopted at any given point of the network, more especially at the crossing of drains, branch pipes for water or gas, as well as at the crossings of roads.

Four copies of this plan are to be supplied, which are to be divided and brought up to date every six months.

Preliminary Notice of the Execution of Works.

ART. 8. Three days prior to the commencement of any work of canalisation, the licensee must give notice of it to the engineers of the municipal service. The same is to apply to all works of maintenance and repairs of the system of distribution, except in relation to researches in case of accident, notice of which may be given on the day when the search is proceeded with.

Additional Paragraph.

The licensee must give simultaneous notice to the President of the Municipal Council and to the Administration of any alterations which he might intend to carry out in the system of distribution, or which in case of urgency may have been carried out by him with the consent of the Administration.

Recovery of the Cost of Restoring Public Work

ART. 9. The licensee shall pay into the municipal counting house, after inspection of quarterly reimbursement accounts submitted to him, the ultimate costs of restoring the public way consequent upon the opening of trenches, whether for the initial laying, or for the maintenance, or, lastly, for the removal of the conduits. These expenses will be based upon fixed prices, as follows:—

Square metre of paved roadway.....	5 francs
" " " stonework	3 "
" " " asphalt pavement	18 "
" " " wood	23 "
" " " bituminous flag	8 "
" " " granite	5 "
Each piece of granite coping, straight or curved..	1 "

Immediately on the execution of any work, and until its final acceptance, the licensee must restore and maintain a provisional means of passage over the trenches opened by him, provided always that this maintenance at his expense shall not be prolonged beyond fifteen days after the embanking in each street.

All restorations of public works necessitated by the establishment of the system of distribution, and not included in the above descriptions, shall be recovered on the presentation of accounts made out in accordance with the verified expenditure.

Observance of Administrative Regulations.

ART. 10. The licensee will be bound in carrying out works to conform to the regulations of the municipal services in connection with the technical direction of the public roads and walks, or of water and sanitary arrangements. The licensee will, moreover, be bound generally, not only in establishing but in working the distributing system, by all the regulations and orders which are actually in force and which become applicable within the period of his authorisation.

(To be continued.)

THE POLICY OF GAS COMPANIES AS TO INCANDESCENT ELECTRIC LIGHTING.*

In regard to the policy of gas companies as to incandescent electric lighting, the general inquiry for information is evidence enough of the importance of the subject. We hear on all sides the questions: (1) What effect will the introduction of an incandescent plant have on our business? (2) What amount of capital does it take to put in such a plant? (3) Can they sell light as cheap as we, and make money? (4) Are gas companies any more favourably situated for furnishing electricity than anybody else?

At the meeting of the association held in Dayton a year ago, you listened to two papers—one entitled "Gas and Electricity: Two Interests or One?" in which the operation of the gas and electric light business, separately and collectively, was discussed; the second having for a subject, "Gas with Electricity," in which the results of a year's experience in running gas and arc light plants collectively were given, accompanied with many practical suggestions of much value to those who had the introduction of an arc plant under consideration. In fact, the ground was so completely gone over that there is very little room left for saying anything new. However, the enormous sales of incandescent electric apparatus during the last year, together with the rapid improvement in the modes of generating and distributing the current, have added much that is of interest on the subject. We hear wonderful stories of a new system whereby the amount of necessary first investment in distributing plant is divided by ten, and at the same time the loss incident to distribution is reduced from 10 per cent. at a distance of half a mile to 2½ per cent., and no consideration whatever shown to distance. Verily, they sound like fairy tales. We might well ask, "Where is it to stop?" It would seem that the limits in these directions had well-nigh been reached.

It is, I believe, very generally conceded that, for some purposes, the arc light is far superior to gas. It has been frequently stated that the introduction of arc lights is accompanied by an increased consumption of gas in the immediate neighbourhood where these lights are used, which increase is directly traceable to the presence of the lights. Will this be the case with the introduction of the incandescent lamps? I believe not.

The popular error that there were millions in the lighting business has given the incandescent promoters command of almost unlimited capital; and with what results? Two examples will suffice to show. The Edison Electric Manufacturing Company claim to have at the present time 68 central station plants in operation, supplying current to upwards of 500,000 lamps, and representing an investment of about 12,000,000dols. (much the larger part of which has been thus invested during the last three years), with many large unfulfilled contracts on hand. In this country the first plant running on the alternating system was put in operation in 1885. At or near the beginning of 1887, the Westinghouse people began to place on the market this form of incandescent apparatus; and in less than eight months they had established fourteen such plants, supplying current to 15,000 lamps, representing a capital of about 350,000dols., with contracts amounting to nearly 120,000dols. on hand.†

In view of these facts, is it not safe to predict that the same energy and push that characterised the locating of these plants will not rest until every town in Ohio, in the business portion of which 500 lamps could be placed, has been afforded the opportunity of using them? And if they are not furnished by the gas companies therein located, they most surely will be by someone else. Would a merchant be called enterprising who allowed a new article of merit, and in his line, and which he could have handled with profit, to be sold to a part of his best trade, to most the exclusion of his own goods, simply because he refused to put it on the market, when he could have

sold it at a less price, and at the same time made as large a percentage on the capital invested as did the other man? On the contrary, I think he would be called "slow."

The sceptical will no doubt ask, "What has all this to do with us?" Let us see. First, the introduction of an incandescent plant into the business district of a town means the loss of the gas consumption of at least one 5-foot burner for each incandescent lamp used. Secondly, the cost of a plant would depend largely on whether the direct current 3-wire or the alternating system were used; and this, as also the cost of running it, would depend on the circumstances under which the plant was to be operated—the distance of the lamps from the station, and the difference in the commercial efficiency of the generating apparatus coming in for due consideration. Supposing that the system requiring the least capital was embraced, we are told that the amount of investment—including land, buildings, steam plant, and complete generating and distributing apparatus erected and ready for use—would average 25dols. per lamp. Adding 10 per cent. to this, as a factor of safety, would make a 1,000 light plant cost 27,500dols.

The third question requires more in reply. We will take, for example, a plant located in a town, the business portion of which would use 1,000 16-candle lamps. With a 16-candle per five cubic feet gas, selling at 1.50dols. per 1,000 cubic feet, taking four hours as the average daily usage, the total consumption displaced per month would be $1,000 \times 5 \times 4 \times 30 = 600,000$ cubic feet, which at 1.50dols. per 1,000 = 900dols., or an average of 90c. per month per burner. Allowing for leakage a little less than 8 per cent., the net profit on the gas sold at that rate to pay 10 per cent. on the capital invested would be 55c. per 1,000 cubic feet, or 3.30dols. per month of 30 days. This would be the net reduction of the profits accruing to the gas business, resulting from the introduction of 1,000 incandescent lamps, if the current was supplied from 6 p.m. until 6 a.m.

Now, suppose the lamps were furnished at the cost of a 5ft. tip—viz., 90c. per month—the income from the 1,000 would be 900dols. per month. No meters being used, charging consumers with the cost of renewals of lamps, the company guaranteeing them to last 800 hours, would have a tendency to limit the hours of use to those specified in the contract; but they would still burn them more than they did the gas-jets. Allowing 33 per cent. for this increase, and dividing the lamps and hours of use thus:—

600 lamps from 6 to 10 p.m.	4 hours	= 2,400 hours.
300 " " 6 " 12 " "	6 " "	= 1,800 " "
100 " " 6 " 6 a.m. 12 " "	6 " "	= 1,200 " "

we have a total of 5,400 hours per day, or an average of 5.4 hours per lamp per day. They would cost, with a consumption of 6lb. of coal per horse-power per hour, and an average efficiency of eight 16-c.p. lamps per horse-power, with coal at 2dols. per ton:—

125 h.p., 4 hours	= 125 × 4 × 6 = 1,500lb. (1)
50 " 2 " "	= 50 × 2 × 6 = 600 " "
12½ " 12 " "	= 12½ × 12 × 11 = 1,650 " "
Coal used for banking and starting fires	350 " "

Total... 4,100lb.

4,100lb. of fuel at 10c. per cwt.	\$4.10
Water at 30lb. per h.p. per hour = 2,664 gals., at 50c. per 1,000 gals.	3.35
Proportion of superintendent's salary	2.00
Engineer and station man	3.00
Fireman	2.00
Day watchman	1.65
Lineman and helper	2.50
Repairs to engines, boilers, and dynamos, at 5 per cent. on investment	15.00
Oil	1.00
Interest, insurance, and depreciation at 16 per cent.	12.25
Taxes	0.60

The total daily expenses would be 32dols., or for an average month (32 × 30½) 976dols. The income being 900dols., this would make a net loss of 76dols. per month. If placed at 90c. for those used until 10 o'clock, and 1dol. for those used until 12 o'clock, and at 2.70dols. for those used until 6 a.m., which would be the cost of a 5ft. gas-burner alight all night, the total income would be 1,060dols. per month; deducting 976dols. expenses, would leave a net profit of 84dols. per month, or 1,008dols. per annum—a little less than 3½ per cent. on the capital invested. Such a plant would hardly be called a *bonanza*.

*A paper read at the annual meeting of the Ohio Gas-Light Association, March 21, 1888, and reprinted from the "Official Report" in the *American Gaslight Journal*.

† Later information credits them with having, up to the present time, put in operation 85 plants, supplying current to 175,000 lamps, and representing an investment of about 5,000,000dols.

In cases where, as Mr. Wood (in his paper on "Gas or Electricity") suggested, the waste heat could be used to such an extent as to save 50 per cent. of the fuel, and the balance could be made up of coke breeze, costing 1s. per bushel to handle, the expense of firing would be reduced at least one-half, making the whole cost of production per day—

For fuel, 2,050lb., at 1 cent per bushel	80.52
Other expenses	27.42
Total	107.94

In round numbers (28dols. \times 30) 854dols. for an average month. With an income of 1,060dols., and an expense of 854dols., we have a profit of (206dols. \times 12) 2,472dols., or nearly 10 per cent. per annum on the capital, as estimated by the Westinghouse people. By the operation of an arc plant in connection with the incandescent, some of the items would be divided, making net earnings considerably larger. The cost as estimated here is, no doubt, larger than it would be placed at by the electrical engineers; but we had better err on the safe side.

The manufacture of a cheap fuel gas made use of in gas engines, together with the advantage of cheap and efficient storage batteries or accumulators, would lower considerably the amount of first investment, and at the same time cut down immensely the cost of production.

It would seem, from the figures here given, that gas companies are much more favourably situated for furnishing both arc and incandescent lights, or electric currents, than anybody else, and that they should pursue the policy of fortifying themselves in their present positions by obtaining authority so to do, if necessary. Keep an eye on the public pulse; and if they will have it, give it them. By so doing they would make a powerful ally of what might, under some circumstances, be a formidable foe. Failure to occupy a field of action in advance of others sometimes results in disaster.

CORRESPONDENCE.

LONG DISTANCE TELEPHONY.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR: I shall be glad if you can find space in your valuable journal for the following information under the above head—

Through the courtesy of Mr. H. F. Jackson, of the National Telephone Company, I recently had the pleasure of speaking over the Sheffield to Manchester and Liverpool trunk line—distance, 144½ miles. Only 35 to 40 seconds elapsed before I was in direct communication with Manchester, and, after finishing conversation, I was switched on to Liverpool in about the same space of time. To both places the conversation was carried on just as easily as if we were only a mile distant. I was also in communication with Leeds and Bradford in similar time. I marked the easy and rapid manner in which the switching was carried out to each town. Having been district manager for the National Telephone Company's Nottingham division for a period of seven years, I can speak from experience upon this subject. I failed to find the slightest interruption from induction influence. I understand that the longest trunk line in Great Britain is from Sheffield to Fleetwood. As soon as Sheffield is in communication with Nottingham—and this line is now being built—the distance from Nottingham to Liverpool will exceed 200 miles as the line will run. Birmingham is also being connected with Nottingham, and with Sheffield and North Yorkshire *via* Derby and Chesterfield. Such communication to these important centres must be a great boon to the commercial community generally. I may also mention that the service from Glasgow down the west coast and to the Scottish capital is most excellent.

A few weeks since, I also had the pleasure of speaking over a long trunk line of the Western Counties Telephone Company, by the kind permission of Mr. H. F. Lewis, the general manager, Bristol, between that ancient city and Llanelli (South Wales)—distance 128½ miles, including a cable across the Severn Bridge. Particulars of towns and distances are given below. I was in communication with

Swansea within one minute, when, after conversation, I was asked to be switched on to Llanelli. This occupied about 45 seconds. The communication was perfect in every respect. The following are the trunk lines, &c., of the Western Counties Company:

From	To	Wire Distance Miles.	Remarks.
Bristol	Bath	14	
do.	Gloster	39	Via Sharpness and Severn Bridge.
Do.	Newport	52½	Do.
Do.	Cardiff	66½	Do.
Do.	Pontypidd	78½	Do.
Do.	Briton Ferry	111½	Do.
Do.	Swansea	116½	Do.
Do.	Llanelli	128½	Do.
Swansea	Llanore	2	
Do.	Morriston	3	
Do.	Neath	6	
Pontypidd	Aberdare	12

Mr. Lewis states that the longest distance spoken by them is from Bath to Llanelli, a wire mileage of 142½ miles. The speaking was in every way perfect and commercially good.

I must not forget, also, that I had the same pleasure extended to me by Mr. C. B. Clay, the General Manager of the Northern District Telephone Company, Sunderland, whose trunk-line system I also give below. I found the switching similar in space of time as over other systems. I failed to observe any induction over any section of the trunk lines, which are erected in the twisted metallic circuit system. The wires in Yorkshire and Lancashire however, are all single, and at the time of my trial were perfectly quiet, though I am informed that there is generally some induction disturbance, though so slight as to be of no practical consequence.

While speaking between Sunderland, Newcastle, Middlesboro', and Darlington, intermediate stations, a heavy thunder storm was reported from these stations, but no interruption was observable, and the conversation, switching, &c., was carried out without the slightest difficulty.

The following are the trunk lines of the Northern District Co.:

From	To	Miles.	Remarks.
Sunderland	Durham	18	Twist system.
Do.	Middlesboro'	40½	Do.
Do.	Hartlepool	25½	Do.

Do.	N Shields	20½	Do.
Do.	Blyth	33	Do.
Do.	Middlesboro'	68	Via Newcastle.

The National Telephone Company, for their local exchanges, for the past five years or more have used bronze wire, manufactured by the Phosphor Bronze Company, Summer-street, Southwark, London, and similar wire is now, and for some time past has been, exclusively used by the Western Counties, South of England, and Northern District Companies for local service, and, I understand, has given universal satisfaction, it having great tensile strength, resistance to oxidation and elongation. The tensile strength of bronze wire not being mechanical after a heavy fall of snow or other strain on the wire, it recovers its normal position, which copper or other wire fails to do, and consequently, where copper wire is used, the cost of maintenance is much heavier, apart from the inconvenience caused to subscribers by the lines being frequently interrupted. As the so-called hard drawn copper in long spans has simply a mechanical strength, being erected in long spans such as it is impossible

to prevent in towns, it gradually loses its strength, whereas bronze wire, after being erected years, remains the same.

Mr. Preece's paper on "Electrical Conductors," read before the Institution of Civil Engineers on Dec. 4, 1883, touches upon this point, an extract of which is given below.

"*Bronze Wire.* Phosphor bronze, whose hard mechanical qualities and great resisting powers are well known, was introduced for telegraph wire about five years ago. Several lengths were erected by the Post Office. Two long spans crossed the channel that separates the Mumbles Lighthouse from the headland near Swansea. The object in view was to obtain great tensile strength with a power to resist oxidation, especially active where the wire is exposed to sea spray. This was done in 1879, and now, in November, 1883, not the slightest change is noticeable in the wire. But phosphor bronze, though extensively used, has high electrical resistance; its conductivity is only 20 per cent. of that of copper. Moreover, the phosphor-bronze supplied was irregular in dimensions and brittle in character. It would not bear bends or kinks. A new alloy, silicious-bronze, has recently been introduced to remedy these disadvantages.

"Phosphor and silicious-bronze derive their names, not so much because the materials prefixed are mixed with the copper, but because they are used in the preparation of the alloy. Pure bronze is a mixture of copper and tin, and in the refining and mixing process phosphorus and silicon have the property of removing impurities, particularly the oxides, though, doubtless, some of the flux remains. Phosphorus has a most injurious influence on the electrical resistance of the alloy. Silicon is far superior; hence the silicious-bronze is preferable for telegraphic purposes. Its efficiency is very great; in fact, phosphor-bronze has disappeared for telegraph wire, and has been replaced by silicious-bronze.

"The electric resistance of silicious-bronze can be made nearly equal to that of copper, but its mechanical strength diminishes as its conductivity increases. Wire whose resistance equals 96 per cent. of pure copper, gives a tensile strength of 28 tons on the square inch, but when its conductivity is 34 per cent. of pure copper its strength is fifty tons on the square inch. Its lightness, combined with its mechanical strength, its high conductivity, and its indestructibility, rendered it eminently adapted for telegraphs.

"Table A gives the results of some tests made by the Post Office upon specimens submitted for trial.

"Long telegraph lines, for which iron wire weighing 400lb. per mile is now used, can be made of bronze wire weighing 100lb. per mile, which would give higher electrical efficiency; and over house lines, for which steel wire is often used, can be replaced efficiently by bronze wire weighing only 30lb. per mile, which would be almost invisible.

"If overhead wires were erected of such a material, upon slightly supports, and with some method, there would be an end to the meaningless crusade now made in some quarters against aerial lines. These, if constructed judiciously, and under proper control, are far more efficient than underground lines. Corporations and local authorities should control the erection, rather than force administrations to needless expense and to reduced efficiency by putting them underground. Not only do light wires hold less snow and less wind, but they produce less electrical disturbance, they can be rendered noiseless, and they allow existing supports to carry a much greater number of wires. Other bronzes have been tried, but without any evident advantage, either in quality or in price."

Yours, &c.,

JAMES O. FRY.

4, Avenue-villas, Cricklewood, N.W.

PHYSICAL SOCIETY, April 28th.

PROF. REYNOLD, F.R.S. (President), in the chair.

The following communications were read:—

"On Electromotive Force by Contact," by Mr. C. V. BURNES, B.Sc. The object of the paper is to discuss the seats of the electromotive forces developed by the contact of conductors. By considering the distribution of electricity on the surfaces of the conductors, and from the fact that the potentials throughout their masses are constant, except about a thin layer near the junction, the author deduces that the molecular action which gives rise to a contact E.M.F. between two conductors is confined to the immediate neighbourhood of the junction. If E be the contact E.M.F., and M the quantity of electricity which passes across the junction when two metals originally at the same potential are placed in contact, it is shown that the work done is EM , half of which is spent in producing heat, and half in raising the potential energy of the system. Since the conductors are supposed to be kept at a constant temperature, and the action which gives rise to the E.M.F. is confined to the immediate neighbourhood of the junction, the molecular energy must be absorbed at the junction. By supposing the surface of contact very small and the capacity of the system large, it is shown that heat and chemical action are the only kinds of energy which fulfil the required conditions of supplying an indefinite amount of energy. Hence, for substances chemically inactive, the true contact E.M.F. is equal to their coefficient of the Peltier effect expressed in absolute measure, and for substances chemically active, but devoid of Peltier effect, the E.M.F. is equal to the energy of combination of one electrochemical equivalent. Since metal-metal contacts are only the seats of Peltier E.M.F.'s, it is inferred that the apparent contact E.M.P. (measured inductively) must be due chiefly to air-metal contacts. A list of analogous properties of Peltier and chemical E.M.F.'s is given in parallel columns. The results of some experiments on the contact E.M.F. of glass and ebonite with mercury are tabulated, but they are very irregular; and the author concludes that there is no true and definite contact E.M.F. between conductors and non-conductors.

Prof. Ayrton, Schuster, Thompson, and Perry discussed the points raised, and it was considered that direct experiment on contact E.M.F. in a very perfect vacuum could alone decide the questions.

"On a Theory concerning the Sudden Loss of Magnetic Properties of Iron and Nickel," by Mr. H. TOMLINSON, B.A. Experiments by himself and other observers have shown that the temperatures at which iron and nickel lose their magnetic properties depend on the specimens used and the magnetising forces employed; but the temperature at which they begin to lose these properties are definite for nickel about 300 deg. C., and iron about 680 deg. C. The author's own experiments on "Recalescence of Iron" show two critical temperatures, and Pinchon has shown by calorimetric measurements that between 660 and 720 deg. C. and between 1,000 and 1,050 deg. C. heat becomes latent. All these facts seem to indicate a molecular rearrangement about these temperatures. In his proposed theory, he assumes that the molecules of iron, say, contain magnetic atoms capable of motions of translation and of rotation. These tend to form closed magnetic circuits, but at ordinary temperatures are unable to do so on account of the close proximity of their centres. On raising the temperature, their centres are further separated till, at about 680 deg. C. their polar extremities rush together, forming complete circuits, and exhibiting no external magnetic properties. On cooling down, the centres approach until the gravitation attraction overcomes the magnetic attraction of their poles, when the magnetic properties reappear. Prof. Ayrton asked whether the author had made experiments on the reappearance of magnetic properties when raised to a white heat, and Prof. Thompson inquired whether cobalt had been tested. Both questions were answered negatively.

"Note on the Graphic Treatment of the Lamont-Frolich Formula for Induced Magnetism," by Prof. S. P. THOMPSON, D.Sc. The formula referred to is $N = N \frac{S_i}{S_i + b}$, where N = total induction when saturated, N = induction due to S_i ampere, turns, and b = value of S_i which makes $N = \frac{1}{2} N$. Simple geometrical constructions are given for plotting the curve when N and b are known, and for finding N and b when two pairs of values of N and S_i have been determined. The use of the formula is shown to be justified in practice, for, as pointed out to the author by Prof. Perry, the curves connecting permeability, μ , and induction, B , are straight lines from $B = 7,000$ to $B = 16,000$, between which dynamos are usually worked. A method of predetermining N and b is given for magnetic circuits of known form and materials thus removing the objection often urged against the above formula—viz., that it involves two constants which had to be determined after the magnet was made—Two other "Notes" by the same author were postponed till next meeting.

Other Places.....	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

GAS COMPANIES AS CONTRACTORS.

The abstract of a paper read in America before one of the gas associations, which abstract we print elsewhere, directs the attention of all those engaged in the gas industry to the question whether it will not be to their advantage to take the bull by the horns, and harness the electric lighting industry to the car they already drive to such good purpose, at least so far as dividends are concerned. Epicures are frequently heard to expatiate learnedly upon acquired tastes. The palate does not take favourably to some kinds of food when presented to it for the first time: but with a little tempting and a little education, that which originally produced a feeling of nausea becomes savoury and agreeable. The electric light is as yet in the nausea-producing stage, so far as the gas people are concerned; but the bait may prove too tempting, and ere long may be swallowed. There is a grand opportunity now, though year by year this opportunity will slip away, and the gas companies, instead of guiding and controlling, will find their power for good or for evil entirely vanished.

*"Knowledge comes, but wisdom lingers, and he bears a laden breast
Full of sad experience, moving towards the stillness of his rest."*

The advice we tender now has been given before, but such was the contempt for the new illuminant, that chairman after chairman presiding at gas companies' meetings treated the possibility of electricity competing with gas as a question unworthy of discussion; the competitor they feared was not electricity; it was oil. Verily, knowledge will come, though wisdom lingers; and the time will come when chairmen will be compelled to acknowledge that the gas industry has something to fear from electricity. However, it is not our intention to sermonise to the directors of gas companies. They are not desirous of being convinced that a little more knowledge is by no means a dangerous thing, but partake something of the character of the sluggard, who, as we all know, was perfectly indifferent to the state of his garden so long as he was not bothered to wake up. But

*"Not in vain the distance bescons. Forward, forward let us range,
Let the great world spin for ever down the ringing grooves of change."*

The change is coming, it is as certain as that the world exists. The luxurious—those who can well afford luxuries—are quietly but quickly replacing the old methods of illumination by the new. They do not affect oil; they invariably replace what went before by means of the far better, purer, and intenser light evolved by electricity. This is as it should be. The light is a luxury; but, like other luxuries, as the demand increases it becomes cheaper, and so gets within the reach of a greater and a greater number, till ultimately what originally was a luxury, and nothing but a luxury, becomes a necessity, and is to be found in every house. Knowledge is increasing, and with the increase it becomes known that the method of comparing the cost of the electric light with that of gas is altogether misleading. If a householder

pays ten pounds a year for his gas bill, and a second ten pounds a year to get cleared away the dirt caused by the use of gas, the cost of the light is just double its nominal cost, and, further, if he can get the electric light for double the nominal cost of gas, he is thereby a gainer and not a loser.

The moral we have to point out is that directors of gas companies are missing the grandest opportunity of the century in not throwing themselves heartily into the work of developing the electric light industry. They are in a position which, rightly used, would give them almost as complete a monopoly of the one system as they have of the other. Their advantages are great. They have generally spare ground. They have a good deal of spare waste heat. They have a cheap fuel in the shape of coke. They have the opportunity of breaking up streets in many instances without danger of troubles arising with the local authorities. If the Acts which authorise their existence have not sufficient latitude, a very little expenditure is necessary to enlarge their powers. No opposition would be likely to be encountered in getting such powers. The shareholders are local men, many of whom, though hankering after the electric light, cannot bring their hearts to favour its introduction, because they think it would tend to lower dividends or the quoted price of their shares. If, however, the gas company were in a position to offer the alternative light, no doubt a sufficient number of subscribers would be found around every gasworks to make even the first little installation a paying concern. If the directors have not sufficient perspicacity to see the tendency of things electric, it is almost time that shareholders commenced to bestir themselves in order to get a management holding wider views, and anxious to be well abreast of the times. The gas interests took fright three or four years ago, when there was really no wolf in existence—only a cub; but that cub has been growing and growing, till it is rapidly assuming all the external characteristics of a full-grown wolf. Familiarity with the growing cub has engendered a contempt the existence of which will probably lead to a rude awakening at no very distant date. If it were not that the innocent shareholders are likely to suffer from the crass stupidity of those who guide the vessels, we should say: let these directors stew in their overweening ignorance; but it is so evident that they do not realise the position of affairs that a warning is necessary. We contend that electric lighting will eventually supersede gas lighting, that the new lighting could be carried out better by the existing lighting companies, with less derangements of interests, with less shifting of capital, and with more rapid extension than by the aid of competing companies. Of course we assume that if the existing companies took up the work it would be with a view of carrying it out satisfactorily, and not in a manner to try and make con-

sumers dissatisfied with it. Any attempt in the latter direction would undoubtedly bring about the catastrophe earnest and honest people are anxious to avoid. This article is sufficiently lengthy without adding more. The suggestion it contains is for consideration. A due appreciation of the signs of the times will prove that it is not ill-timed. Town after town is enquiring—a few will adopt the electric light. The enquiries will continue if the light is fairly successful, and the percentage adopting the light will become greater and greater. With regard to the success of the light, the gas journals are filled with a simpering inanity of ifs and buts, of flouts and jeers, all to make believe that the word failure is writ large upon every bit of work of the electric engineer. A greater mistake could not be made. Failures there are, and always will be. Good work is not always paid for, and sometimes when paid for is not given; but many engineers will guarantee success under all ordinary circumstances, and will, with greater confidence, daily point to a dozen successes to one failure. There is not hope for the scornful in this direction.

PRIESTMAN'S PETROLEUM ENGINE.

In our last issue we gave the report of Prof. Jamieson on the Griffin Gas Engine. Such engines, of course, suppose that the gas required for their working could be obtained, either from the gasworks in the vicinity, or—perhaps, preferably so far as economy is concerned—by using the Dowson process for making the gas as required. This week we illustrate an engine which possesses many advantages, one of which, and possibly not the least, is that it only consumes a material which is easily obtained everywhere, and does not depend upon the erection either of a small special plant, or the vicinity of the works. We refer to Priestman's latest form of the Eteve engine. We have before us a number of reports as to the performances of this engine, and we have ourselves examined one at the offices of the firm in Queen Victoria street. Sir Wm. Thomson in his report, among other things, says:—

"I made careful tests on a 6-h.p. engine. After seeing it started and stopped several times, and kept running on the brake for an hour at $7\frac{1}{2}$ -h.p., and for two hours at 6-h.p., without measuring the oil, I gave it exactly an hour's run with the brake loaded slightly more than for 6-h.p., and with arrangements to measure the oil accurately. The result was that the engine ran with very admirable regularity at from 158 to 160 revolutions, doing 6.43 h.p. on the brake. The quantity of oil used was very exactly 11 pints, being at the rate of 1.71 pints per hour per brake horse-power, or 1.69 pounds per hour per brake horse-power, which seems to me remarkably good economy, considering the great difficulties which had to be overcome in using the combustion of oil directly as a motor. It must be noted that these results refer to the horse-power of work actually done externally by the engine, and not merely to 'indicated horse-power,' which in the steam engine, and still more in the gas-engine, falls short of true horse power by a large difference. Messrs. Priestman's engine, unlike one upon another system to which my attention has been called, does not use only the lighter portion of the oil, leaving a large residuum, which cannot be utilised, but has the great advantage of consuming the whole of the oil put into the cistern, which I verified by careful examination of the working of the engines which I tested. By a new and effective mode of regulating the supply of vapour to the cylinder, combustion so perfect is obtained that deposit of carbon in the cylinder and passages is most satisfactorily

obviated, as I have myself verified by careful examination. As the engine is governed by reducing the charge admitted into the cylinder, instead of cutting off the supply, the explosion takes place with great regularity, thus securing steady running with or without load, and with varied loads, which, judging from my own experience of the irregular running of gas-engines, running at anything less than full load, is a very important advantage."

The following details are taken from a report of Sir Samuel Canning and Messrs. Alabaster and Co. as to an engine at work at the Electrical Power Storage Company:

"The cylinder is 10in. in diameter, with 15in. stroke; the fly-wheel being 5ft. 6in. in diameter. The engine runs regularly, whether with full load or light, at about 160 revolutions per minute. Our tests were made with a brake, also with a dynamo used for charging secondary batteries, giving, it was said, 85 per cent. of the engine power in the external circuit. This efficiency does not appear to be exaggerated, as, according to the tabulated results, the oil consumed per brake h.p., and with the dynamo at 85 per cent., agree closely. However, to be within safe limits, we have also given the results at only 80 per cent. The following table gives the result of one hour's run with brake:—

Revolutions per minute	160
Brake horse power	6.438
Oil consumed, in pints	10.8
Oil consumed, in pints, per h.p.	1.68

At the end of the trial, the cylinder and the points and insulators in the sparking or firing plug were found to be

engines of the type tested by us, it is evident that the employment of petroleum, even at the price here quoted, will compare favourably with gas in this and other countries at any price above 3s. 6d. per thousand cubic feet."

EXPERIMENTS ILLUSTRATING THE PRINCIPLE OF THE DYNAMO.

BY GEO. M. HOPKINS.

II.

After noticing the effect of plunging a magnet into a coil of wire, it is not very difficult, in the light of present electrical knowledge, to understand how the process of induction is carried on in a continuous way in the armature of a dynamo.

The simplest form of armature for illustrating this point is undoubtedly that known as the Gramme ring armature. In the action of this armature the prime factor is magnetic induction. It is perhaps unnecessary to go into the details of the construction of the Gramme ring as commonly used in dynamos. A very crude ring answers the present purpose. Its core is formed of a compact circular coil of soft iron wire, which, in cross section, may be circular or of any other form. The core is wrapped with tape, and varnished to insure insulation.

Around this iron ring or core is wound an insulated copper wire, arranged in a spiral coil, *f*, like the winding of an

Priestmann's Petroleum Engine.

quite clean. A second test of three hours' duration was made on the following day with a dynamo, charging secondary batteries, substituted for the brake, the results of which are embodied below:

E. M. F. volts	77.1
Ampères average	57.0, 58.75, 57.5, 57.5
Average Electrical H.P.	6.0
Total oil consumption	35 pints
Consumption per electrical h.p. hour	1.82 "
Oil per h.p., delivered at 80 per cent.	1.55 "
Oil per h.p., delivered at 85 per cent.	1.65 "
Delivered h.p. at 80 per cent.	7.5 h.p.
Delivered h.p. at 85 per cent.	7.06 h.p.
Cost per h.p. hour at 80 per cent.	1.25 pence
Cost per h.p. hour at 85 per cent.	1.34 pence
Revolutions of engine	160 per min.

The current was measured by means of an Ayrton and Perry instrument, checked by a standard Siemen's electro-dynamometer, and the readings of an accurately and recently calibrated voltmeter were corrected for temperature. It appears, then, that the cost per actual horse power is approximately 1½d. per hour, with oil at 6½d. per gallon; but as the probabilities are greatly in favour of considerable reduction in its price, it would seem that in the near future a very great economy will accrue from the employment of this engine. We may add that the maintenance of the battery (zincs and solution) for supplying electrical energy to the induction coil would cost about 60s. per annum, or about 2½d. per day of nine hours. For

ordinary electro-magnet. The ends of the copper winding are joined by soldering, thus forming a closed coil. The ring is mounted upon a circular wooden support attached to a spindle, so that the armature may be revolved in front of the poles of a magnet, *a a'*, as shown in Fig 9. In the wooden

FIG. 9.

support, in a circle concentric with and near the spindle, are inserted six or eight wire nails, *a'*, arranged at equidistant points. The copper winding of the ring is spaced off into as many sections as there are nails in the circular row, and at the end of each section the insulation of the

copper wire is removed a short distance, and a wire, *i*, is attached by soldering. These attached wires are each connected with one of the wire nails. Now, all that remains to complete the Gramme dynamo or motor is the application of two conductors, *g g'*, to the circular row of wire nails, as shown in Figs. 10 and 11.

FIG. 10.

FIG. 11.

This dynamo has all the essential features of the regular machine—the field-magnet, the iron armature core, the conductor wound upon the core, the commutator cylinder formed of the wire nails, and the brushes consisting of wires held on opposite sides of the commutator cylinder.

This dynamo is constructed for illustration only, and not for practical use. It will generate a current, and may be driven as a motor by a current, but of course not with the same advantage as a more complete machine.

In investigating the phenomena of the armature, it is well to begin with the simplest case of magnetic induction. When a bar of soft iron is held before the poles of a magnet, as shown in Fig. 12, it becomes itself a magnet.

FIG. 12.

FIG. 13.

The magnetism developed in the bar by the action of the magnet is opposite that of the magnet. That is, the magnetism developed in the end of the bar opposite the N pole of the magnet is S, and, similarly, the magnetism developed in the end of the bar opposite the S pole is N. The centre of the iron bar is neutral.

By substituting an iron ring for the straight bar, as shown in Fig. 13, the effect will be the same. The portions of the ring opposite the poles of the magnet acquire polarity by induction, as in the first instance, and the magnetism extends in the ring from the vicinity of the poles toward the neutral line, X X, which forms a right angle with a line joining the poles of the magnet. In the figure of the ring the location of the magnetism in the ring is indicated by the shading.

FIG. 14.

By turning the ring upon its axis, the mass of the ring moves, but the polarity of the ring maintains a fixed position relative to the poles of the magnet.

When the ring carries a coil, as shown in Fig. 14, the magnetic poles of the ring remaining stationary, while the

material of the ring and coil are revolved. There is a continual passing of the sections of the coil through the magnetic field surrounding the polarised portions of the armature core and the poles of the magnet, which is the same in effect as the passing of a magnetic bar through the coil of the armature.

Besides the inductive effect produced by the magnetisation of the armature core, the passing of the conductor through the magnetic field of the inducing magnet augments the current.

Each half of the armature between the neutral points is practically a single coil of wire, terminating at two of the commutator bars—which in the present case are the two nails—at diametrically opposite sides of the commutator cylinder: all of the remaining commutator bars and their connections being idle.

In Fig. 9, two circuits are shown in connection with the machine—one in full lines, the other partly in dotted lines—both connected with the battery, *c*. When the circuit, represented in full lines, only is employed, the machine runs as a motor. When the wires, shown by full lines, are disconnected from the brushes, *g g'*, the rotation of the armature in the field of the magnet, *a a'*, produces a current in the manner already indicated, and this current is taken from the armature by the way of the wires, *i*, the nails, *c'*, and the brushes, *g g'*.

This machine, when used as a generator, is strictly a magneto electric machine, although an electro magnet is employed as a field-magnet. A permanent magnet might be substituted for the electro-magnet.

For the sake of securing the greatest possible simplicity, certain modifications of the action of the armature have been omitted.—*Scientific American*.

ELECTRICAL TRAMWAYS: THE BESSBROOK AND NEWRY TRAMWAY.*

BY EDWARD HOPKINSON, M.A., D.SC., ASSOC. M. INST. C.E.

(Continued from page 402.)

Comparing the proportion of the total energy of the water, which can be applied to traction in the electrical locomotive, with the proportion of the total energy of coal, which can be usefully applied in a steam locomotive, the former has been seen to be over 40 per cent. Mr. G. C. Cunningham, M.Inst.C.E., estimates the latter from experiments tried on the Canada Southern Railway at 3.5 per cent.*

Referring again to Table IV., if the work done against gravity be subtracted from the total work done by the motor, the remainder represents the work done against all the frictional resistances. From this and from the distance traversed the mean tractive force can be at once deduced. The results for the three journeys are, respectively, 28.9, 27.4, and 37.1 lb. per ton of gross load hauled. The two former agree well. The increase in the third is due to two causes: first, the mean speed is nearly double that in the first journey, the effect of which on the mean tractive force would be increased by the frequent and sharp curves of the line; secondly, the locomotive car having no trucks attached to it on the third journey, the friction of the driving gear, connecting rods, &c., would bear a much larger proportion to the whole. The values given above for the tractive force include the friction of the chain and driving-gear, as also that of the motor dynamo in its bearings, and the couple required to turn the armature with the fields excited, but no current passing through it. It corresponds in a steam locomotive to the product of the mean pressure on the piston and the ratio of the throw of the crank to the radius of the driving-wheel.

The foregoing results also afford some examples illustrative of the general theory of a series-wound motor. In such a motor let *L* be the couple on the armature shaft; *R* the resistance of the series coils and armature; *r* the additional resistance inserted; *C* the current; *P* the potential of the conductor; *E* the electromotive force of the motor; and ω the angular velocity of the armature. Then

$$L \omega = E C$$

$$\text{And } E = P - R + r C.$$

* Minutes of Proceedings, Inst. C.E., Vol. LXXXV., p. 325.

L_{00} here includes the power lost in the armature of the dynamo through the reversal of its magnetisation, the power lost through the short-circuiting of successive coils at the commutator and local currents in the core, also friction of the bearings, in addition to the useful work done by the motor, as measured by a brake. The first of these losses, which is, or ought to be, the most important, is proportional to the velocity ω , and the latter, with sufficient accuracy for the present purpose, may be assumed to be so. ($L + l$) may therefore be written for L , where L represents the couple doing useful work external to the dynamo. Let $E = \frac{\omega}{\Omega} f(C)$ be the characteristic curve of the dynamo, then

$$L + l = \frac{C f(C)}{\Omega}$$

C is therefore independent of the velocity, and depends upon the couples only. It must be remembered that C being measured in amperes, L and l are measured in the corresponding C.G.S. unit of work denominated by the late Sir William Siemens a "Joule." (One Joule = 10^7 ergs = 0.74 foot-lb.) Since within very wide limits $f(C)$ increases as C increases, $L + l$ increases as C increases. In this lies the chief advantage of a series wound dynamo for locomotive purposes. The maximum couple which a steam locomotive can exert is limited by the steam-pressure and the area and stroke of the piston. In a water wheel the couple cannot exceed the product of the radius of the wheel and the maximum weight of water its buckets can contain. So in a turbine. In a series-wound dynamo there is no limit to the couple it can momentarily exert, except the mechanical strength of the armature, provided the potential of the conductor does not fall below $R + r C$. It may be said that the current is limited by the couple turning the generating dynamo. This no doubt is true, but in many cases the generating dynamo is sufficient for working several motors, and the motor which at the instant requires to exert the greatest pull can draw the full current of the generator; and in every case there is the momentum of the generating dynamo and of the engine or other prime motor driving it, which must be exhausted before the amount of current is limited. In the present instances, the motors on the cars are designed for working continuously with a current of 72 amperes, with which current the couple the dynamo exerts is 183 Joules, or 135 foot-lb., which is increased to 1,120 foot-lb. on the axle, equivalent to a tractive force of 960 lb. The observed current required to start a train of 29 tons on an incline of 1 in 50 was 170 amperes (Plate 1, Fig. 1), corresponding to a tractive force of 2,544 lb., equal to 88 lb. per ton, or about three times the normal tractive force exerted by the motor. For a line such as the one under discussion a simple shunt-wound motor would be useless, since at the moment of starting on a steep incline the potential of the conductor at the motor may be reduced to one-half its normal amount through the resistance in circuit, and consequently the magnetising force reduced in like proportion, when the fields would almost entirely lose their magnetism. A compound-wound machine might be used, and would have the advantage that the speed would not exceed a certain limit however small the load might be, but in the present instance such a provision was unnecessary. A further advantage in the use of a series wound machine is the facility with which a motor of the Edison-Hopkinson type when wound in this manner can be reversed. In general, to reverse the direction of rotation of a motor, the lead of the brushes must be reversed at the same time as the current through the armature, or there will be destructive sparking at the commutator. But if the lead can be reduced to such an extent that the brushes may be fixed at the neutral point without causing injurious sparking, it is only necessary to reverse the current. It is known that the angle of lead depends upon the disturbance of the magnetic field in the gap between the pole-pieces, due to the current round the armature, but no successful attempt has yet been made to express the variation of the angle of lead in terms of the geometrical constants of the machine and the magnetising forces. The disturbance of the field can, however, be minimised by maintaining the magnetising forces in the field magnets

very large compared with those in the armature, as is the case in a series wound machine. In the present instance it has been found unnecessary to make any provision for the change of lead, and the reversal of rotation is effected by reversing the current only.

Referring to curves, Plate 1, Fig. 1, it is seen that on an incline of 1 in 521 the locomotive car, when drawing a gross load of 28.6 tons, absorbed a current of sixty amperes, and that the electromotive force of the motor was 222 volts. From these measured results the couple exerted by the motor and the speed can be readily determined by aid of the characteristic curve. With a current of 60 amperes through the magnet coils, the electromotive force of the motor is 260 volts at a speed of 1,000 revolutions per minute, and, therefore, with 222 volts the speed will be 854 revolutions per minute, corresponding to a speed of travel of 8.57 miles per hour as against 8.4 miles measured. Again, the couple exerted by the motor will be

$$\frac{222 \times 60 \times 60}{854 \times 2\pi} \text{ Joules} = 149 \text{ Joules} = 110 \text{ foot-lb.}$$

This is equivalent to 913 foot-lb. on the axle of the car, or a tractive force of 785 lb., i.e., 27.4 lb. per ton. From this must be deducted 3.4 lb. per ton for gravity, leaving 24 lb. per ton, as against 28.9 lb., the tractive force calculated from the mean of the work done over the complete journey. In the latter the force required to overcome the resistance of the curves, which are both numerous and sharp, is included, whereas the former figure applies to a straight portion of the line. This is probably sufficient to account for the difference between the figures. The example shows how precisely the results obtainable from an electromotor when used for locomotion can be calculated.

USE OF STORAGE BATTERIES.

It is interesting to consider how far the system of storage batteries would be applicable to a line where heavy traffic has to be accommodated. In the first journey, with a load of 28.6 tons, the total work done by the motor was 12.6 h.p. hours, and the loss in the motor was 2.07 h.p. hours, hence the total electrical energy absorbed by the motor was 14.67 h.p. hours in thirty-six minutes, or at the rate of 24.4 h.p. According to results published by Mr. Reckenzaun in a communication to the American National Electric Light Association, a cell suitable for tramcar work weighing 41 lb. has a useful capacity of 137 to 156 ampere-hours, according as the rate of discharge is varied from 46 to 22 amperes; the electromotive force falling during discharge from 2.1 volts to 1.87 volt. Hence one ton of storage cells can do work usefully at the average rate of 3,700 watts, or 4.9 h.p. From these data the weight of battery required to do the work actually accomplished at Beasbrook can be readily deduced. Remembering that the battery itself has to be carried, and making no allowance for increased weight in the framework of the car, the weight of battery required is six tons. But this additional weight would necessitate a considerably larger locomotive power with a stronger frame and more powerful motor, which would again increase the weight of the train and the weight of the cells required. If the former be taken at 4.4 tons, the latter would be about one ton; hence the gross weight of the train would be increased to 40 tons, including the battery, weighing 7 tons. Assuming the efficiency of the battery to be 70 per cent., which is probably a favourable assumption when the rate of discharge is variable, the electrical energy required to charge the battery for one journey would be 29.3 h.p. hours as against 16.4 h.p. hours required for the same work on the continuous conductor principle. Thus, from the point of view of economy of power, the comparison is greatly in favour of the continuous conductor. There are the further considerations of first cost and depreciation of plant. To provide for the continuous working of the line, two sets of accumulators would be required, which, taken at the present price of £60 per ton, would cost £840, to which must be added the cost of the larger locomotive cars and more powerful motors. This would increase the cost to at least £1,200. Now, the cost of the conductor, which is the only part replaced by the battery, was £600 (see appendix). Again, the depreciation

of the cells cannot be estimated at less than 40 per cent. per annum, whereas the conductor practically suffers no depreciation.

COMPARISON WITH WIRE-ROPE TRACTION.

Traction by a continuously moving wire rope has many points in common with an electrical system on the continuous conductor principle, and the efficiency of the two methods can be readily compared. In a comprehensive review of the working of the cable tramways in San Francisco, Mr. Hauscom* gives the following results obtained from careful measurements on seven different lines:

Total indicated power of engines	798.7 h.p.
Total power absorbed in moving the cables	546.2 "
" " " cars and passengers	250.5 "

Hence on the average 32 per cent. of the total indicated power is available for moving the cars and passengers. Now, in comparing this with the results obtained on the Bessbrook line, it must be remembered that a portion only of the net power developed by the motor is available for moving the cars, part being required for moving the motor and its carriage. About 3.5 tons of the total of 28.6 tons represents the dead weight, and hence about 88 per cent. only of the net power is available for moving the effective load. Again, if for water-power steam power were substituted, about 15 per cent. of the indicated power would be available for driving the generator dynamo. Hence, the ratio of the power available for moving effective load to the total indicated power would be 54 per cent. as against 32 per cent. on the cable system.

In instituting the above comparison, both systems may be considered to be working under conditions calculated to favourably develop the characteristic features of each. The grades on the San Francisco lines are in cases as steep as 1 in 6, and 1 in 10 is not uncommon. On such lines any system of electrical propulsion, except, perhaps, by a geared locomotive, would be entirely inapplicable. On the other hand, the wire-rope system would present less favourable comparative results, if applied to a line similar to the Bessbrook line, where the gradients are less severe. The paper is accompanied by a series of drawings, from which Plate 1 and the Figs. in the text have been prepared.

APPENDIX.

Cost of Construction.

The cost of the electrical equipment of the line may be briefly summarised as follows:—

Turbine, penstock, and driving gear	£330 0 0
Two generator dynamos, measuring instruments, and driving belts	450 0 0
Conductor, at £200 per mile	600 0 0
Two locomotive cars, including their entire electrical equipment	1,120 0 0

£2,500 0 0

Each of the above items include delivery and erection.

Cost of Working.

The cost of haulage was carefully ascertained over a period of five months from November 21st, 1885, to April 22nd, 1886.

Wages of driver and attendant at generator station	£32 7 6
Sundry repairs	6 1 0
Oil, grease, and waste	5 4 10
Rental of water power	59 16 0
Dynamo brushes, renewals of driving chain, and commutators	14 11 6

£118 0 10

Train-mileage, 8,652.

Hence cost per train mile, 3.3d.

For the six months ending June 30th, 1887, during which period there had been a goods traffic of 8,000 tons over the line, a much larger amount than in the period referred to above, the cost per train-mile was somewhat greater, as follows:—

Wages	£50 18 0
Sundry repairs and alterations, including the cost of changing the winding of four armatures of the dynamos	34 14 3
Oil, grease, and waste	10 0 0
Rental of water power	71 15 0
Dynamo brushes and sundry renewals	12 5 10

£179 13 1

Train mileage, 10,176

Hence cost per train-mile, 4.2d

The above figures do not include anything for depreciation or for general supervision.

THE MAXIMUM EFFICIENCY OF INCANDESCENT LAMPS.*

BY JOHN W. HOWELL.

The word efficiency, when applied to an incandescent lamp, is used to designate the amount of energy required by the lamp for the production of a given amount of light; thus we say that a given lamp has an efficiency of 3 watts per candle, at 16 candles, meaning, that to produce an illumination of 16 candles we must supply the lamp with 48 watts.

* A paper read before the American Institute of Electrical Engineers, April 10, 1888.

The word efficiency, when applied to a prime mover or to any piece of apparatus that changes energy from one form to another, or which transmits or utilises energy, has a well-defined meaning, and is used to represent the ratio of the energy of the useful effect produced by the apparatus to the energy necessarily supplied to the apparatus to enable it to produce that effect.

An incandescent lamp transforms electrical energy into heat and light, so the use of the word efficiency to denote the watts per candle required by the lamp is not a proper one. To denote properly the efficiency of an incandescent lamp, we must be able to separate the energy of the light produced by it from the energy of the heat produced. Then the ratio of the energy of the light to the electrical energy required by the lamp will be a correct expression for the efficiency of the lamp, and we will have to find some other word to designate the watts per candle. In this paper the word efficiency is used in its ordinary improper sense to denote the watts per candle required by a lamp when producing a given amount of light.

The efficiency of a lamp varies with its candle-power. The curve, Fig. 1, shows the rate of this variation for a particular lamp. At five candles this lamp has an efficiency of 6.7 watts per candle; at ten candles it is 4.2 watts per candle, and at 20 candles it is 2.66 watts per candle.

Any statement regarding the efficiency of a lamp must, therefore, be accompanied by a statement of the candle-power at which it has the stated efficiency, without this it is meaningless. There is nothing in an incandescent lamp itself that fixes its proper efficiency or in any way indicates what it is. The lamp, from which the curve, Fig. 1, was determined has, within the limits of the curve, any efficiency between 2 and 7 watts per candle. Thus, by simply

FIG. 1.

FIG. 2.

changing the candle-power of the lamp, we can operate it at any efficiency we choose, and get as much or as little light per watt as we choose.

In commercial practice the candle-power of lamps is always marked on them, and their efficiency at this candle-power is stated; but even this is not a proper index to the value of the lamp or to its proper efficiency. Experience has shown that lamps are almost universally run above their normal rating; lamps rated at 4.5 watts per candle are usually run at from 3.5 to 4 watts per candle, and in order to make lamps that will stand the strain of being run above their rated capacity, it is necessary to rate them considerably below the efficiency at which they will give the best results under ordinary circumstances.

Lamps have been made and sold in England which have a very high-rated efficiency, but parties buying these lamps are told that they will get very much more satisfactory results if they run the lamp below their rated capacity. So we see that some lamps are rated above their capacity and some are rated below, and the rated efficiency of a lamp is not always the best efficiency at which to run it. How, then, are we to determine the efficiency at which a lamp will give the best results? It is this question which I will attempt to answer.

The term "maximum efficiency" of a lamp, as used in the title of this paper, does not mean the highest efficiency at which a lamp can be operated, but the efficiency at which the best results are produced by the lamp, or more accurately, the efficiency at which the cost of operating the lamp is a minimum.

Taken in this latter sense, the maximum efficiency of a lamp is not its highest efficiency. As we increase the

candle-power of a lamp, its efficiency increases; consequently, by running the lamp high enough, we can make its efficiency so high that very little power is required to produce a given amount of light, and the cost of the power to produce the light is very small. But, while the efficiency of the lamp increases, its life decreases, and if we run a lamp at too high an efficiency the saving in the cost of power is more than balanced by the increased cost of lamp renewals.

To determine the maximum efficiency for lamps under given conditions, we must determine the efficiency at which the sum of the costs of power and lamps is a minimum, and in order to do this we must know the rate of variation of the life of a lamp with its efficiency.

The curve, Fig. 2, shows this rate of variation. This curve is the result of very carefully conducted experiments made by the Edison Company. These experiments extended over five years, and consumed a very large number of lamps. Its accuracy when applied to Edison lamps is beyond question; but our experiments with lamps having an artificial surface on the carbon, or "flashed" lamps as they are called, show that their rate of variation of life and efficiency follows a different curve.

This curve does not apply to individual lamps. If we take two Edison lamps and burn them at different efficiencies, their lives for these efficiencies will probably not be such as indicated by the curve, nor will they be proportioned to these indicated lives. But if we take one hundred lamps and burn them at one efficiency, and another hundred equally good lamps and burn them at another efficiency, the average lives of the two sets will be proportional to the lives indicated by the curves for these two efficiencies.

In order to determine at what efficiency the cost of operating lamps of a given quality under given conditions is a minimum, we must calculate what this cost is at different efficiencies. To do this we consider the total cost

FIG. 3.

FIG. 4.

of operating the lamps to be made up of two parts—viz., the cost of the current and the cost of the lamps. The cost of the current is made up of every expense incurred in operating the lamps, including materials consumed, labour, taxes, insurance, rent, and every other expense incurred in operating the plant, except the cost of lamps. The cost of the lamps is an item by itself, and is the amount which the lamp has cost when it is put in use. This is a natural division of the total cost of operating a plant, since to produce light by incandescence, all that is necessary is a lamp and current to operate it.

If in any case we know the cost of the current required to operate the lamps, the cost of the lamps, the quality of the lamps—that is, the life they will give when burned at a given efficiency—and the rate of variation of their life with efficiency, we can then calculate at what efficiency the cost of operating the lamps is a minimum, and this I call the maximum efficiency of those lamps.

The following examples show what this maximum efficiency is under varying conditions of the cost of lamps, the cost of current, and the quality of the lamps. The cost of the lamps I have varied between 25 cents and 1.00dols. each. The cost of current varies between 2.5 cents and 10 cents per horsepower per hour. The quality of the lamps varies between 300 hours' life at 3 watts per candle, and 2,400 hours' life at 3 watts per candle.

In each of the following cases I have calculated the cost of operating 100 16 c.p. lamps 1,000 hours at each of the efficiencies comprised in the curve of total cost. These curves do not show the cost of running the same lamps at different efficiencies, but the cost of running equally good 16 c.p. lamps of the different efficiencies.

rst case we will consider is shown in the diagram. In this case the lamps are assumed to cost 85 cents and to have a life of 600 hours at 3 watts per candle. The current is assumed to cost 10 cents per horse power

cost of the current is determined from the following

Cost =

$1 \times 16 \times 100 \times 1,000 \times \text{cost of ct. per h.p. per hour}$

746

the cost of lamps from this formula

Cost of lamps = $\frac{\text{cost of one lamp} \times 100 \times 1,000}{\text{Life at given efficiency}}$

Curve marked *total cost* shows the total cost of running 16 c.p. lamps, 1,000 hours, the efficiencies of the lamps varying between 2.5 and 4.25 watts per candle.

FIG. 5.

FIG. 6.

efficiencies are shown by the vertical lines, referring to the scale at the bottom. The value of the total cost at any point on the curve is shown by the horizontal line through that point, referring to the scale at the left of the diagram.

The lowest point of the curve shows the point where the total cost is lowest. This is the minimum cost of operating lamps under the given conditions. The mark at the point of the curve shows this minimum cost to be 444 cents, and a vertical line through this point to the bottom of the diagram shows that this total cost is obtained when lamps having an efficiency of 3.1 watts per candle are used.

The maximum efficiency of these lamps under the conditions assumed is 3.1 watts per candle.

Lamps considered in the case shown in Fig. 4 cost 85 cents; all other conditions are the same as in the case shown in Fig. 3. This increases the total cost from 746 to 800 cents, and necessitates using lamps of 3.18 watts per candle instead of 3.1, to make the cost of operation a minimum.

In the case shown in the diagram, Fig. 5, the current costs 10 cents per h.p. per hour; the other conditions are the same as in the case assumed in Fig. 4. The minimum total cost in this case is 444 cents, and to make this cost a minimum must use lamps having an efficiency of 3.5 watts per candle.

FIG. 7.

FIG. 8.

In the case, shown in Fig. 6, the lamps cost the same as in the case shown in Fig. 5, but are only half as good, the current costs just as much as in the last case. The minimum total cost in this case is 273 cents, and the maximum efficiency of the lamps is 2.62 watts per candle.

In the case shown in Fig. 7 the lamps cost 50 cents, and have a life of 1,200 hours at 3 watts per candle. The current costs 10 cents per h.p. per hour. This is the cheapest case of the best lamp we have yet considered, but the current is very expensive. In this case the minimum total cost is 444 cents, and the maximum efficiency of the lamps is 2.62 watts per candle. In this case, Fig. 8, the current costs 5 cents per h.p. per hour, such as in the previous case, other conditions being the same. The minimum total cost is reduced from 444 to 362 cents. The maximum efficiency in this case is 3.1 watts per candle. In Fig. 9 the current costs twice as much as in the previous case, and the lamps are only

half as good. The minimum total cost is doubled, but the maximum efficiency is the same as in the previous case.

In this case, Fig. 10, the current costs one-half of that assumed in the previous case, other conditions being the same. The minimum total cost is 100 cents, and the maximum efficiency 3.175 watts per candle.

The curve, Fig. 11, illustrates the case of very cheap and very good lamps, with moderate cost of current. The minimum total cost is low, 294 cents, while the lamps are run at the high efficiency of 2.38 watts per candle.

In the case shown in Fig. 12, the cost and quality of the lamps are the same as in the previous case, but the current costs twice as much. This increases the minimum total cost from 294 cents to 535 cents, and raises the maximum efficiency to 2.14 watts per candle.

FIG. 9.

FIG. 10.

In the case, Fig. 13, the cost of lamps and the cost of current are the same as in the case shown in Fig. 11, but the lamps are only half as good. The minimum total cost is increased from 294 cents to 327 cents, and the maximum efficiency is reduced from 2.38 to 2.62 watts per candle.

The first and plainest inference drawn from these curves is that the maximum efficiency of any given lamp is not a fixed one, but varies with conditions outside the lamp itself. Identical lamps operated under different conditions of cost of current must be burned at different efficiencies to make the cost of operation a minimum for the production of a given amount of light. In order to determine the maximum efficiency of lamps, therefore, we must know the quality of the lamps referred to some standard, the cost of the lamps to the consumer, and the cost of current under the actual conditions existing at the place where the lamps are to be used.

In the eleven cases shown in this paper the lamp of highest efficiency is obtained in the case shown in Fig. 12. This is a case where the lamps are very cheap and very good, and current is very expensive. The lamp having the lowest efficiency is obtained in the case shown in Fig. 6, in which the lamps are poor and high-priced, and the current is very cheap.

There is a marked difference in the sharpness of these curves at the minimum points. An inspection will show

FIG. 11.

FIG. 12.

that the sharpness of the bend in these curves depends upon the cost of the current, the curves in which the current costs 10 cents per h.p. per hour being the sharpest. Those in which the current costs 5 cents are next, and the one, Fig. 6, in which the current costs only 2½ cents per h.p. per hour, is very flat at the bottom or minimum point. In this comparison Fig. 7 is not considered, as it is drawn on a different scale from the others, and is not as sharp as it should be.

This indicates that the more expensive the power is, the more carefully must the lamp efficiencies be chosen. In Fig. 12, which shows the sharpest curve, a very slight variation in the efficiencies of the lamps makes a very great change in the total cost of operation. In the case shown in Fig. 6, in which the current is very cheap, we find that a very considerable change in the efficiency of the lamps used makes very little difference in the total cost of operation.

On each of the eleven diagrams two curves are drawn, one showing the total cost of operation, and the other showing the cost of lamps. On each of the curves showing the cost of lamps a point is marked which indicates the cost of the lamps when the total cost is a minimum. The letter T, marked on each of the figures, denotes the minimum total cost of operating the lamps under the given conditions. The letter L denotes the cost of the lamps when the total cost is a minimum; and the expression $\frac{L}{T}$ denotes the ratio

of the cost of lamps when the total cost, is a minimum, to the minimum total cost. An examination of all these curves shows that while the minimum total cost varies with each of the three quantities—price of lamps, quality of lamps and cost of current—nevertheless, the total cost is always a minimum when the cost of lamps is about 14.5 or 15 per cent. of the total cost of operation.

This figure varies somewhat in the different examples considered, but the variation seems to follow no law. In Figs. 6 and 12, which show the highest and lowest efficiency lamps, the figures are 15.1 per cent., and 15.4 per cent. respectively.

The steepness of the curve showing the cost of lamps, and the difficulty of determining the exact minimum point of a curve which has been drawn by inaccurate methods, makes it difficult to get the cost of lamps accurately when total cost is a minimum. These curves and values are given just as they were determined, and no effort has been made to bring the results into closer agreement, as could readily have been done. I consider the variation shown by these curves to indicate closely enough that this ratio of cost of lamps to total cost at the minimum point is nearly, if not quite, constant, and that its value is between .145 and .15.

FIG. 13.

This establishes a very simple law for determining whether or not lamps are being operated at their maximum efficiency; for if they are, the lamp bills will be about 15 per cent. of the total operating expenses of the plant. If the lamp bills are more than 15 per cent. of the total operating expenses, the lamps are being burned above their maximum efficiency, and lower efficiency lamps should be obtained. If, on the other hand, the lamp bills are less than 15 per cent. of the total expenses of the plant, the lamps are being burned below their maximum efficiency, and higher efficiency lamps would reduce the cost of operating the plant. Where fuel is high priced, or where other causes operate to make the cost of generating current high, it is specially important to use lamps of the maximum efficiency; for we have seen from the above curves that where the cost of current is high, the use of lamps whose efficiency is a little above or below the maximum efficiency attainable under the conditions of operation makes a very marked increase in the operating expenses of the plant.

If in any plant the lamp bills are only 10 per cent. of the total expenses, then increasing the efficiency of the lamps by increasing their candle power does not diminish the total cost of operating the plant. In order to reduce the total cost, the lamps must be replaced by lamps of the same candle power, but of higher efficiency. If the efficiency of the lamps is increased by raising their candle power, the cost of operating the plant per unit of light produced is reduced, but the total cost is increased. A plant which is paying less than 15 per cent. of its total expenses for lamps, and which brings the lamp bills up to 15 per cent. by increasing the candle power of the lamps, does not decrease the cost per lamp of operating the plant, but does decrease the cost per candle of light furnished. If they are paid for the increased light given by the lamps, the efficiency of the plant is made a maximum for the existing conditions; but if they are not paid for the additional light furnished, the efficiency of the plant is reduced.

This law enables anyone operating an incandescent lamp plant to determine whether or not he is using the most suitable lamps for his plant. If the conditions of operation of a new plant are all known, and the quality of the lamps made by any lampmaker is known, we can determine before starting what is the most economical lamp to use.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS

An ordinary general meeting of this society was held on April 26, Mr. E. Graves, president, being in the chair.

In opening the proceedings Mr. Graves referred to the recent death of Mr. T. R. Crompton, who, he said, had been a member of the society for many years, and who was specially known for the service he had rendered to electricity in first introducing the type of submarine cable, that was used for the first successful cable between Dover and Calais laid in 1851, which had continued to be used up to the present day and existed all over the world.

Sir Douglas Galton moved: "That the members of the society have learned with deep regret the decease of their much esteemed member, Mr. T. R. Crompton, who was intimately connected with the establishment and laying of the first successful submarine cable, and they desire to offer the expression of their sympathy with his widow and with the other members of his family on the loss they have sustained," and said that Mr. Crompton was a born engineer, and besides introducing the type of submarine cable which had been so universally adopted, had introduced a form of locomotive which still held its place on several railways in France.

The motion was seconded by Prof. Forbes, and unanimously carried.

CENTRAL STATION LIGHTING—TRANSFORMERS v. ACCUMULATORS.

The adjourned discussion on Mr. R. E. Crompton's paper, on "Central Station Lighting—Transformers v. Accumulators," was resumed.

Mr. W. B. Eason said that Mr. Crompton's paper would have been much more valuable had he confined his attention solely to the experience obtained at Vienna, instead of adopting figures expected to be obtained from a hypothetical case. Accumulators, so far, had not given a return higher than 60 to 61 per cent., and seeing that they required a charging force of 2.5 volts, and only discharged 2 volts, it was highly improbable that in actual practice they ever gave more than 70 per cent., if, indeed, that figure was ever reached. He would not like to put down means to distribute from four centres, at an aggregate of 600 volts, at the price mentioned by Mr. Crompton, if he had the Bank of England at his back. He agreed with Mr. Crompton that the cost of alternating current dynamos would be more than the £5,000 or so that he had put down. Calculations that he had made brought out the total of £7,500, but the type might be improved and cost less in the future. In working expenses he thought there was little choice between transformers and secondary batteries. They had a figure yet of the actual cost of an alternating current transformer system, and he wished that those who were interested in its working would show their coal bills. As to reliability also, he thought there was very little to choose between the two systems. Dynamos might break down in either one, and the remedy for that was to have a spare reserve ready. So much had been made of the reliability of the accumulator. As to the matter, there were two systems of distribution before them—one maintained low potential, 100 volts, and the other at high potential, 2,000 volts. He would view with distrust any ramification of mains placed underground having the high potential of 2,000 volts, and that transformers were used which distributed the current at 100 volts. The cost of distribution would be about the same as Mr. Crompton put down for accumulators. The cost of the main for charging accumulators was much larger than the cost of alternating transformer main, some six or eight times as large, and that was the only material difference in the two systems. He had before referred to the use of continuous current transformers, and had pointed out how very easy they could be used in conjunction with accumulators, and he hoped someone would remark upon that later on.

Prof. G. Forbes, F.R.S.: I think that the paper which has given rise to this discussion is of a character which ought not generally to be read before the society. It is unfortunate that a paper should be read based merely upon a hypothetical case instead of upon actual facts. The discussion has taken the form of a general discussion upon the distribution of electricity. I am very sorry that Mr. Crompton was not here to night, as I particularly wish him to hear what I have to say. It is extremely unfortunate that he did not give us a paper upon the installation which he tells us has been successfully worked on which would bear out the results of the paper itself. He would have been able to give us some information about the action of the accumulators used at Vienna and Kensington, about the amount of current put into them, the amount taken out, and a great deal of other valuable information. He may say that we can judge for ourselves from the Howell accumulators at Kensington, and that we can judge for ourselves from the facility for doing so; but I have never been able to find the means of determining the value of an accumulator from simply looking at it while working at a central station. Instead of making the comparison of other methods alluded to at the beginning of his paper, he has made one, as it happens, the least advantageous—that of accumulators. But if he proved his case in this instance he has not proved the case of other methods, because he has merely taken the single case of

small station with 10,000 lights at a distance of 2,000 yards. It does not follow that transformers would not be the more useful in a larger station with a greater number of lights. If he had gone into the figures of the numerous other systems, there is not the slightest doubt, in my mind, that the system which is neither the accumulator nor the transformer system, found most economical, would be the Stanley system, mentioned in Mr. Mackenzie's excellent paper read a short time ago. As an example of the cost of these different systems of distribution, I may mention the work which I did two years ago after I had published the theoretical work. I took the special case, in London, of the late district of Pall mall, St. James's street, and St. James's square. I got information from all the secretaries of the different clubs as to the number of hours of lighting the different rooms, the number of lights in each room, and everything. I devoted a considerable length of time, with the assistance of Mr. W. H. Smith, to working out the cost of the different systems, and I will give the results arrived at. The cost per candle-power per annum was, with the simple parallel system, 2s.; the 2-wire system, 1s. 10½d.; the multiple-series system, 1s. 10d.; the multiple-series system complying with the Board of Trade regulations, about 200 volts difference of potential, 2s.; the simple-series system, like Mr. Brompton's, 1s. 10½d.; the secondary generator system, 1s. 10½d.; and with secondary batteries, 1s. 4d. The chief points in Mr. Crompton's paper are the two tables showing the cost of the installation and the cost of maintenance. There are distinct errors in them, and I will point out the errors which produce the fallacy of the results arrived at. In Table III. 600 kilowatts are given as the maximum. I cannot do better than illustrate my remarks on this paper by mentioning the practice in America which I have had opportunities of examining in all the details in the last few months. It is found most positively that the return of the Westinghouse transformer is more than 600 kilowatts in the lamps for the indicated horse power. Mr. Crompton, for a 600 kilowatt station, has demanded 1,450 h.p., instead of 1,000 h.p.—that is to say, he has added 50 per cent. to the actual power required as a maximum. That, he would say, was intended for reserve, it is enormously beyond what the reserve requires. Reducing those figures to their proper dimensions also reduces the cost of generating station, buildings, chimney shaft, water tanks, and general fittings, taken for the alternating transformer system at £11,000, and for the accumulator system at £8,000. The cost of dynamos and accessories is correct, in accordance with the American figures, including station switches, resistance boxes, voltmeters, ammeters, lighting a meter, compensators, synchroscopes, and speed armatures, ball bearings and brushes. The price of transformers is given as £7,500, instead of £4,000. The mains are the point on which Mr. Crompton has made the greatest error. He has not appreciated the value of the transformer system in economizing mains. In his proposed scheme he proposes 220,400 and 22,000 yards of underground mains for a wretched station of 10,000 lights. These charging mains which carry the current only 300 amperes at the maximum, and are going to dig up wooden paving and concrete, build a trough and put one conductor of 3½ inch diameter at the bottom of it. It is simply absurd that we should take a case like that as illustrating the way in which the transformer system should be applied. If we are to put down such a small station under these conditions it most undoubtedly ought to be by overhead wires; but then immediately the cost falls down enormously. But with the other systems which are at our disposal, the three-wire system and any other, the current is enormous, and is not anything like 300 amperes, and it would be impossible to put a single conductor carrying that current overhead. Even in Mr. Crompton's case, in which he is using a potential of 480 volts—a potential which he is not allowed to use in this country which he cannot use—the current which he is carrying is 1,500 amperes, and he is using conductors whose sectional area is 2.55 in. You cannot have wires like that along all the way overhead. Such massive conductors must be put underground, and still more would it be necessary if a system complying with the Board of Trade regulations were adopted. Consequently, I notice Mr. Crompton's calculations for the mains in the alternating system to £6,000. Thus, I find that the total cost of the alternating transformer system for the proposed case is £39,140 instead of £57,440, and thus we have the comparison between the alternating and accumulator systems, the cost for the latter being, if we accept Mr. Crompton's figures on all points as being correct, £59,762. Having pointed out the sources of error in dealing with the alternating current system I will now point out what are the sources of error in connection with the accumulator system which are sufficient to throw doubt upon the accuracy of these results as regards efficiency. For the combined efficiency of the conductors and accumulators Mr. Crompton says that "for the output of 2,100 units it will be sufficient to work the generating plant for about five hours at approximately its greatest rate of efficiency. I have had ample experience with this class of plant, and know that we can actually in practice produce the electrical h.p. at the terminals of the dynamo with the expenditure of 3½ lb. of coal." Good, gentlemen. "Taking the maximum loss in the accumulators, the efficiency of the system—that is, the electrical h.p. at the lamps divided by the electrical h.p. at the terminals of the dynamo—will be not less than 80 per cent. therefore we may say that each unit at the lamps can be produced for 5.75 lb. of coal"—a Board of Trade unit for 5.75 lb.—that is 4.3½ lb. of coal per h.p., which is simply 20 per cent. added on to the 3½ lb. of coal, 3½ lb. of coal for the work given out at the terminals of the dynamo, and only 20 per cent. loss over the whole of the conductors, and that is taking into account the working of the batteries as well. He has told us in the paper that he will admit a loss of 10 per cent. in his charging mains, and 4 per cent. in his distributing mains, making 14 per cent. As a matter of fact I have worked it out, and I find that his charging mains have a loss of 12 per cent. instead of 10 per cent., which will make 16 per cent. altogether. I do not know how his distributing mains are worked, and I must accept his 4 per cent. for them—that is, 16 per cent. out of

the 20 per cent. is due to the charging mains, and 4 per cent. loss in the efficiency of the accumulators, assuming that he employs accumulators giving an efficiency something like 96 per cent. Mr. Crompton also tells us that the average rate at which the accumulators are to be able to discharge is 416 amperes for five hours, giving a capacity of 2,080 ampere hours, and they are also to be capable of the very rapid discharge at an efficient rate—the enormous rate of 1,362 amperes. In his final table of the working of accumulators, he puts the depreciation down at 15 per cent. I know of no company who will furnish accumulators and work them at that rate of maintenance. Mr. Press has told us that with the cells used for lighting his house, which are carefully attended to, and which have 16½ active material, there is 1½ lb. of the active material lost in the first year. At what rate the loss goes on in subsequent years, or how many years it takes to destroy the cell, I cannot say; but I am perfectly certain that a 15 per cent. depreciation is not sufficient. I am perfectly certain that if Mr. Crompton had given in the actual facts gained at Vienna and Birmingham, the results would have been totally different from what he has claimed in the paper. He says "Up to the present date far too much attention has been paid to the capacity, and too little to the rate of possible maximum discharge." This state of things has lately been remedied, and I can tell there are several makers of accumulators, who can supply them to fill the above-mentioned conditions, and at the reasonable price, named by me in my report, of £240 per cell. That is simply ramour—he has been told it. Likewise, the facts stated for the alternating current system are stated to have been simply from hearsay information, because, he says, "For the purposes of my comparison, I take the system as generally described by Mr. Kapp in his paper on transformers, or by Mr. Mackenzie in his paper on transformers, and in an article in *Electrician* dated December 7th, 1887, for which, I believe Mr. Kapp is responsible, and which gives very complete data on the first cost of an installation for 10,000 60 watt lamps burnt simultaneously." Thus, undoubtedly, the want of practical experience with the alternating current system is the reason why he has fallen into the errors I have pointed out. I am sorry to see that in the early part of his paper Mr. Crompton made a statement to the effect that the experience which has been gained in America and in other places with the alternating current system "does not help us much in our investigation." I should say that it would help us infinitely more than the reading of any number of papers he may have laid hands on. I say that in the few months I have been studying the system in America I have gained much practical information, such as is applicable to either such a station as Mr. Crompton has taken, or to any other, than I could have obtained from reading the papers of all the authors who have written in this country on the subject. Before leaving the question of estimates I would refer to Mr. Crompton's remark that "a great deal of nonsense has been talked about the cost of conductors being proportional to the cost of copper." I dare say that may be so, I do not remember it, but do not let us talk any more nonsense on the subject. He says that his tables are sufficient to show that we must not consider the cost of laying the conductors as in any degree proportional to the cost of copper. I say that in overhead wires you must consider that it is so, and, while I would not wish to see overhead wires laid for a really large installation, still in a small installation of 10,000 lights, I think they ought to be laid. When I have previously dealt with the question of distribution I have dealt with an installation of 100,000 lamps, and that is the size which I hope we shall have to deal with in a town having a population of 4½ millions. Now, let us look at Mr. Crompton's table No. 2, showing the cable dimensions and the cost of laying them. There the cost of laying small cables is out of all proportion to the cost of the copper, but when you come to a cable of 3½ inch section the cost of laying becomes gradually very small compared with the cost of the copper, and the cost of the copper and its insulation when cables capable of carrying the high current required to supply 100,000 lights are required, is nearly equal to the cost of laying. It may be taken as absolutely assured that the cost of copper is roughly proportional to the cost of laying. As indisputable proof of the accuracy of his figures, Mr. Crompton says he is prepared to lay down an accumulator system, such as he supposes, at the cost put down for it. He may be, but he will not have the opportunity, as it is not allowed in this country. I know plenty of people who are perfectly willing to lay down an alternating current system to supply such a district for the figure he has given, £57,440. It is perfectly certain that that can be done. Here my criticism of Mr. Crompton's paper ends. I intend sometime to give somewhere a full account of the alternating current system as used in America, and I had thought some account of it might have been interesting here to-night. Perhaps I may take up a few minutes longer of your time for that purpose. One fact occurs to me as bearing upon Mr. Crompton's estimate for attendants at the central station. The cost of keeping up a central station in America struck me from a commercial point of view more than anything else there being few men, and a small amount of labour and supervision employed. Denver, with a capacity for 7,000 lamps, retains one manager at \$150 a month, a secretary at \$80 a month, and an office boy; it has two dynamo attendants, five firemen, two inspectors who go over the lines, and one repair man. That is a station where coal is used. At Pittsburgh, Alleghany, and East Liberty, coal is not used, but natural gas. At such stations one solitary man attends to the whole of the boilers for a 10,000-light plant. The natural gas and air to be consumed are let in through pipes controlled by a valve, which is regulated by the pressure of steam in the boilers. Westinghouse engines are chiefly used, and they are fairly, though not very, economical. They give but little trouble, and the governor, which runs in and out, is extremely sensitive. The dynamo machines are of quite a different form to those hitherto used in this country. I presume we have now given up the use of alternating dynamos that have iron in the armature. There is no doubt that the iron in the armature is the essential feature of a good alternating-current dynamo. The Westinghouse machine consists

of a large outside ring attached to the framework, with pole pieces projecting inwards. The armature is of the drum form, and consists of a large number of thin sheets of metal; it is wound in a special way. The machine is mechanically and electrically excellent. The heating is very little indeed, and the exciting power is 2 per cent. of the total power developed. Three types of machines only are made—650 light, 1,500 light, and 2,600 light. The number of revolutions per minute for the larger machine is 1,000 per minute, the resistance of the armature 15 ohm, and the weight 18,000 lb. Much progress is being made with the Parsons's generator, which is likely to become one of our economical machines. In testing the converters at Mr. Westinghouse's works at Pittsburgh, I adopted the calorimetric method described here some time ago by Prof. Ayrton, and which has been used by M. Roux with the Gaulard-Gibbs apparatus, and from a 30 light machine with a half load I got 95 per cent. My time is now up, but I would say a word about the manufacture of dynamos and converters at Mr. Westinghouse's establishment. Only three types of dynamos and five types of converter are made. To make a single converter ten different machines have to be employed, each of which is capable of turning out its parts at the rate of from 50 to 100 per day, and by using such machines, which are always ready to turn out exactly to scale, the apparatus can be supplied at an extremely low figure. The parts of such machines are all interchangeable, consequently, if a part fails, another can be telegraphed for immediately. Some of the smaller parts of the Westinghouse system of distribution are now on the table. The central station switch-board used in America is smaller and compact, compared with the gigantic things used in this country. I have also placed on the table a specimen of the MacIntyre form of joint which is used for joining wires.

(To be concluded.)

COMPANIES' MEETINGS.

EASTERN EXTENSION COMPANY.

The 29th ordinary general meeting of the Eastern Extension, Australasia, and China Telegraph Company, Limited, was held on Wednesday at Winchester House, Sir John Pender presiding.

The **Chairman** stated that the net revenue had been £117,889, or £26,819 more. For the whole year the gross receipts had been £451,861, being an increase over those of 1886 of £10,062, and the working expenses had been £145,812, or £16,029 less. An interim dividend of 1½ per cent. had been paid for the half year, and it was proposed to pay a similar dividend on the following day, making with previous distributions 5 per cent. for the year. They also proposed to distribute a bonus of 3s. a share, which would increase the total return for the last year to 6½ per cent., or ½ per cent. more than for 1886. The balance of £53,051 had been carried to the general reserve fund, which now stood at £620,096. The completion of the renewal of the Singapore-Saigon section with brass ribbed cable had been carried out since the close of the half year, the cost of which, amounting to about £17,000, would be dealt with in the accounts for the current half year. That gave them a new cable entirely brass ribbed between Singapore and Saigon, paid for out of revenue. During the current year they proposed affecting important alterations in the Malacca Penang cable at the Nicobar Islands, and in the Java-Australian cables off the Lombok Strait. These changes would probably cost £75,000; but it was anticipated that they would effect considerable improvement in the working, and a large saving in the cost of repairs. They had been unable to obtain a renewal of the cable lately from the New Zealand Government, and they had, therefore, been obliged to raise the tariff over the New Zealand cable. In that way they had nearly recouped themselves for the loss of the subsidy. Their negotiations with the Chinese Government had resulted in an agreement, and everything was complete in connection with that matter except the signature. They had since the last meeting completed an arrangement with the Netherlands Indian Government for a cable of 462 miles. That Government would pay for the cable, which would be a feeder to the Company's system. He concluded by moving the adoption of the report and the declaration of the dividend and bonus recommended.

The **Marquis of Tweeddale** seconded the motion, which was carried unanimously.

The retiring directors and auditors were afterwards re-elected, Mr. John D. Pender being appointed a member of the Board in the place of the late Sir W. M'Arthur.

WESTERN AND BRAZILIAN COMPANY.

The 15th ordinary general meeting of the Western and Brazilian Telegraph Company, Limited, was held on Thursday, at Winchester House, 111 Broad Street.

Mr. W. S. Andrews, who presided, stated that he had been elected chairman of the Company owing to the retirement of Sir H. D. Wolff, on the latter's appointment as British Minister to the Court of Persia; and to fill the seat at the Board thus vacated Lord Richard Browne had been appointed. He then congratulated them on the continued improvement in the position of the Company. As regarded the current year, too, a satisfactory increase had so far been shown in the receipts as compared with those for the corresponding period of 1887, and the increase would have been larger but for an interruption to one of the cables. The increase of £21,000 in last year's revenue compared with that for 1886 had been earned at an additional outlay of 8 per cent. After crediting the reserve fund with £15,000, and putting £10,000 to the debenture redemption fund, they were enabled to pay a dividend of 3 per cent., making 4½ per cent. for the year, leaving £3,464 to carry forward. For some time they had had before them the importance of doing something to certain sections in order

further to strengthen the system. Any new cable would be obtained by tender, and for part of the cost their reserve fund would probably be appealed to. He concluded by moving the adoption of the report and the payment of the dividend mentioned.

Mr. H. Weaver seconded the motion.

In reply to questions, the **Chairman** stated that the length of the cable was 3,700 miles, and the lines were working all right from end to end. There were no negotiations now pending with the Brazilian Government.

The motion was adopted, and the retiring directors and auditor were re-elected.

An extraordinary general meeting was afterwards held, when resolutions were submitted for altering clauses 6, 7, 26, and 50 of the articles of association (removing certain clauses which were acknowledged to be objectionable, and providing also for the holding of half yearly meetings of the Company; for approving an agreement between the Company and the London-Platina Brazilian Telegraph Company, and for that purpose, and other purposes of the Company, increasing the capital to £1,500,000 by creating 30,090 shares of £15 each, to rank *pari passu* with the existing ordinary shares of the Company).

Mr. Guesdon approved the proposed changes in the articles of association, but advocated further improvements in them, especially the abolition of the power of the Directors to issue stamped proxies.

The alterations in the articles having been agreed to, the **Chairman** read the proposed agreement between the Company and the Platino Company.

The **Chairman** then explained that by what was proposed the two companies would be brought under a common control, with a common proprietary, though an actual amalgamation would not be effected. Of the capital of £1,500,000, about £345,000 would go to the Platino Company if all their shares were exchanged for those of the company in the manner proposed, and 7,090 shares would remain unissued.

In the course of the discussion which followed, objection was taken to the proposal to give the Directors of the Platino Company £6,000, or shares in the Company of the nominal value of £9,000, as compensation for their loss of office.

The **Chairman** explained that it was part of the arrangement; and in the future the Directors of the Company would do the work for nothing which had hitherto been performed by the Directors of the other Company.

The resolution approving the agreement was eventually passed with 12 dissentients. The other resolutions for increasing the capital, &c., were afterwards agreed to.

INDO-EUROPEAN TELEGRAPH COMPANY.

The twenty-first ordinary general meeting of the Indo-European Telegraph Company, Limited, was held on Monday, at Winchester House, 111 Broad Street.

Colonel James Holland, who presided, stated that the revenue for 1887 had been £104,290, or about the same as for 1886. The Indian messages, however, had contributed between £6,000 and £7,000 less, and it was a discouraging fact that that traffic, the tariff of which they had reduced, still remained unelastic. Fortunately, their receipts had been made up by other sources of revenue. There had again been a decrease in their expenses, which had been altogether £2,152 less than those for 1886. They had added £10,000 to the reserve fund, which now stood at £102,463, but the securities representing that fund were, at the market prices of last week of the value of £110,775. They were carrying forward a larger balance. The cost of maintenance had been very low, but it should be remembered by the shareholders that a large outlay might have to be made at short notice. He concluded by moving the adoption of the report and the declaration of a dividend of 1s. 6d. a share, making, with the interim dividend 6 per cent. for the year, and a bonus of £1 a share, both free of income tax, making in all 10 per cent. for the year.

Mr. J. Herbert Tritton seconded the motion.

The **Chairman**, in reply to questions, said he quite agreed that a reserve fund of 25 per cent. on the capital was a very fair amount as an ordinary rule, but there were special difficulties connected with the Company which made them think that they had not yet quite reached the amount at which the reserve fund should stand. If a war broke out in any part of Europe they would be affected, because Germany and Russia—the latter undoubtedly—would be closed to them. They hoped, if peace were maintained and trade recovered, that they might be enabled to divide more of their profits, but at the same time he could not help saying that the return they were now proposing was a very good one, and it should be remembered that the increase of the reserve fund added considerably to the market value of their shares.

The resolution was carried unanimously, and the retiring directors and auditors were re-elected.

PROVISIONAL PATENTS, 1888.

APRIL 20.

- 5870. Improvements in electric batteries. Robert Ransohke, of the firm of Mayer Meltzer and Co., Commercial Street, Haidau.
- 5899. Improvements connected with ships' engine room telegraphs. William Chubburn, 15, Water Street, Liverpool.
- 5900. Improvements connected with mechanical telegraphs for use in navigable vessels. William Chubburn, 15, Water Street, Liverpool.
- 5911. Improvements in railway rolling stock and in the arrangement of switches, and of motors for electrically propelling same. Michael Holroyd Smith, 55 and 56, Chancery Lane, Middlesex.

13. **Improvements in electric telegraph, telephone, and electric-light insulators.** Arthur West Havers, 7, Grafton Road, Whiteley, near Ashton-Tyne. (Complete specification.)

12. **Improvements in connections especially suitable for joining electric conductors.** George Stuart, 24, Southampton-buildings, London, W.C.

APRIL 21

57. **Improved galvanic salt.** Augustus Collingridge, 97, Newgate-street, London, E.C.

APRIL 24.

16. **New and improved method of heating by means of electricity.** Ellis Ekan Ries, 11, Wellington-street, London, W.C. (Complete specification.)

5. **Electrical appliances for a mariner's compass to give alarm upon deviation from the ship's course.** Augustus Green, 45, Southampton-buildings, London, W.C. (Complete specification.)

23. **Improvements in "Morse linker" apparatus for telegraphic purposes.** Frank Jacob, 28, Southampton-buildings, Chancery-lane, London, W.C.

10. **An improved form of locking electrical indicator.** Joseph Torr Tedman, 21, Finsbury-pavement.

APRIL 25

53. **Improvements relating to electric arc lamps.** Frederick Richard Boardman and Francis Teague, 71, Onslow-road, East Dulwich, London, S.E.

17. **Improvements in lanterns for electric arc lamps, and in posts or columns for supporting the same.** Richard Edwin Keen, 45, Southampton-buildings, London, W.C. (Complete specification.)

APRIL 26.

34. **Improvements in telephones.** Mark Rudle, of the firm of Sanderson, Rudle, and Co., 4, Mansfield-chambers, 17, St. Ann-square, Manchester.

1. **Mode of preparing carbons for electric lighting.** Carl Anton Johannes Hugo Schroeder, 17, Althorpe-road, Upper Tooting, London, S.W. (Complete specification.)

4. **Improvements in laying underground electric conductors.** Charles William Farquhar, 24, Southampton-buildings, London, W.C.

SPECIFICATIONS PUBLISHED.

JANUARY 27, 1887.

53. **Improved means of oxydizing and decomposing by electrical action organic matter and inorganic salts in sewage, water, and other liquids.** William Webster, junr., 23, Southampton-buildings, Chancery-lane, London, W.C.

MAY 6, 1887.

13. **Improvements in and connected with electrical distribution by means of direct or alternating currents, chiefly for lighting purposes, and in electric measuring instruments which may be used therewith.** James Swinburne, Shaws, Chelmsford, Essex.

MAY 13, 1887.

38. **An improved apparatus for signalling by electricity.** Harold Humboldt Sater, 36, Wray-mews, Tollington-park, and Arthur Samuel Newman, 14, St. John's-square, both in Middlesex.

MAY 21, 1887.

16. **An improved process for the preparation of aluminium, aluminium bronze, and alloys of aluminium by electrolysis.** Arthur Charles Henderson, 46, Southampton-buildings, Holborn, Middlesex. (Paul Louis Toussaint Herault, France.)

MAY 25, 1887.

8. **Improvements in electric transformers, induction coils, or induction resistance coils.** William Morris Morley and Charles Edmund Webber, C.B., 47, Lincoln's-inn-fields, London, W.C.

MAY 31, 1887.

7. **Improvements in registering meters for electric currents.** Henry Tudor, 6, Lord-street, Liverpool.

JUNE 4, 1887.

3. **Improvements in holders for incandescent electric lamps.** Henry Bayley, 2, Bernard-street, Walsall, Staffordshire.

JUNE 9, 1887.

4. **Improvements in the electro-deposition of the heavy metals.** Silvanus Phillips Thompson, 52, Chancery-lane, London, W.C.

JUNE 11, 1887.

5. **A telephone apparatus without a diaphragm.** Frederick William Neale, 165, Fleet-street, London, E.C.

JUNE 24, 1887.

1. **Improvements in the construction of dynamo-electric generators and motors.** Edward Jones, 6, Bream's-buildings, Chancery-lane, London, E.C.

OCTOBER 27, 1887.

22. **An improved electric accumulator.** Ernest Edward Vaughton, 94, Trinity-road, Birchfield, Birmingham.

MARCH 9, 1888.

3678. **Improvements in and relating to electrical signalling on railways, and in apparatus therefor.** Wybants George Ophitts, Gray's Inn Chambers, 20, High Holborn, London, W.C.

MARCH 20, 1888.

4258. **Improvements in station indicators.** Thomas William Munroe, 519, Seventh-street, Washington, D.C., United States.

MARCH 21, 1888.

4561. **An improved battery jar.** Charles Alva Brown, Somerset Chambers, 151, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

4220. **Measuring electric currents.** W. J. King. 8d.

4447. **Measuring, &c., currents of electricity.** P. R. Elwell. 8d.

4832. **Carbon plates for primary batteries, &c.** H. Liepinann. 8d.

6028. **Miners' safety lamps.** A. S. Hanselaar. 8d.

1888

3097. **Secondary voltaic batteries.** R. M. Drake and J. M. Gorham. 6d.

NEW ELECTRICAL COMPANIES.

Bournemouth Electricity Company, Limited.—Registered by Hooper and Son, 69, Ludgate-hill, London, E.C. Capital £50,000, divided into 10,000 shares of £5 each. Object: to enter into and carry into effect an agreement with Messrs Phillips, Harrison, and Hart, of No. 2, Victoria-mansions, Westminster, electrical engineers, of the one part, and the Bournemouth Electricity Company, Limited, of the other part, to enter into and carry out contracts for lighting the town of Bournemouth with electricity, and maintenance of the same. The first subscribers are:

	Shares.
H. Joy, landowner, Seabrook-Poole road, Bournemouth	1
J. C. Harvey, Classy, Bournemouth	1
J. H. Moore, architect, Southbank, Bournemouth	1
E. Dyke, merchant, Southbank road, Bournemouth	1
J. Kilham, hotel-keeper, High-hill Hotel, Bournemouth	1
H. Patten, bank manager, Old Christchurch road, Bournemouth	1
W. H. Dore, house proprietor, Bournemouth	1

The number of directors shall not be less than three nor more than twelve, and the first shall be determined, together with the remuneration, by the subscribers to the memorandum of association.

The Telephone Companies.—The United Telephone Company has, says the *Financial News*, taken time by the forelock, and has registered two companies, which are to include the whole of the telephone companies in the kingdom. The first company registered was the Telephone Union, Limited, with a capital of £10,000,000. In order to escape the new tax, which would amount to £9,000, this huge company was registered rather hurriedly, so another has also been provisionally registered with the title of the United Kingdom Telephone Company, Limited, and when the arrangements for the federation of the telephone companies are completed it will be decided which of the two is to be abandoned and which carried through. The articles of association of the second company will be signed by the chairman of the whole of the subsidiary telephone companies and by the Board of the United. The following particulars have been obtained at Somerset House of the Telephone Union, Limited:—Registered by Ashurst Morris, Crisp, and Co., 6, Old Jewry, E.C., with a capital of £10,000,000, divided into 2,000,000 shares of £5 each, with power to increase and from time to time to issue any shares of the original, or of new capital, with any preference or priority in the payment of dividends or the distribution of assets, or otherwise over any other shares, whether ordinary or preference, and whether issued or not, and to vary the regulations of the Company so far as necessary to give effect to any such preference or priority, and upon the subdivision of a share to apportion the right to participate in profits in any manner as between the shares resulting from such subdivision. Object: to acquire upon any terms, and for any purpose the whole or any part of the property, business, goodwill, and undertaking of any association or person in the United Kingdom or elsewhere, carrying on, or in the case of a company or association formed, or empowered to carry on, any business and exercise any patent rights, privileges, licences or monopolies relating to telephones or any telephonic apparatus, or to any method, instrument or appliance employed, or to be employed, in connection with the use of electricity as a means of communication, or as a motive power or otherwise, or employed or to be employed in or for the generation, production, storing, application or distribution of electricity in any manner or for any purpose. The first subscribers are:

	Shares.
J. Morris, 6 Old Jewry, E.C.	1
J. Brand, 65, New Broad-street, E.C.	1
F. Crisp, 6, Old Jewry, E.C.	1
J. H. Brand, 65, New Broad-street, E.C.	1
J. B. Morgan Oxford-court, Cannon-street, E.C.	1
S. Edwards, 24, Fenchurch-street, E.C.	1
D. Parrish, 2, Copthall-buildings, E.C.	1

The Company is registered without articles of association, and consequently the regulations of Table A in the first schedule of the Companies Act, 1862, apply.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The estimated traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended April 27 amounted to £4,222.

Union Electrical Power and Light Company.—An order was made by Mr. Justice Chitty, on Saturday, for the compulsory winding up of the Union Electrical Power and Light Company.

Eastern Telegraph Company. The Eastern Telegraph Company announce the payment, by interest warrant, of interest for the half-year ended 30th April, 1888, on their Four per Cent. Mortgage Debenture Stock.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ended April 27, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,524.

London Platino Brazilian Company.—The Directors of the London Platino Brazilian Telegraph Company recommend the payment of a final dividend on and after the 15th inst. of 3s. per share, free of income tax, for the year ending March 31, making with the previous interim dividend a total of 21 per cent. The transfer books will be closed from the 11th to the 15th inst. inclusive.

New Firm. Mr. V. S. Allpress, late assistant to Mr. W. H. Massey, and Mr. T. O. Beshaw, late of the Edison-Swan Co., have joined hands and commenced business as electric light and power engineers and contractors. The firm has its offices at 3 and 14 St. Margaret's-terrace, Victoria-street, S.W. Both the gentlemen comprising this firm have had considerable experience in the best class of electric lighting work.

London Platino Brazilian Company.—A special general meeting of the London Platino Brazilian Telegraph Company, Limited, was held on Friday at Westminster House, Old Broad-street, to consider a proposed agreement with the Western and Brazilian Telegraph Company. Sir John Peaker, who presided, moved a resolution approving the agreement, which after some discussion, objection being taken to the compensation proposed to be given to the directors for the loss of their office, was agreed to.

West Coast of America Telegraph Company.—The report of the West Coast of America Telegraph Company, Limited, shows a

gross income of £57,893 for the year ended the 31st of December, against £43,026. After deducting debenture interest and all other charges, there remained a net profit of £23,115, as compared with £11,037. After adding the amount brought forward, and allowing for the £15,000 paid in dividends, the Directors recommended writing off £1,558 from the value of the reporting steamer "Retriever," then by reducing her valuation in their books to £17,500, and to add £7,000 to the reserve fund, making the latter £27,000, leaving £334 to be carried forward.

Brazilian Submarine Telegraph Company.—The report of the Directors of the Brazilian Submarine Telegraph Company, Limited, for the half-year ended December 31, 1887, shows a revenue of £102,594 the working expenses being £12,812. After providing for debenture interest, making fund, and income-tax, there is, including the balance brought forward, a total of £76,916. First and second interim dividends amounting to £39,000 have been paid, and £25,000 transferred to the reserve fund, leaving £12,916 to be carried forward. In accordance with the provisions for repayment of the first issue of debentures, dated the 31st July, 1884, 139 bonds, representing £13,900, were drawn on the 26th of April for payment at par on the 31st July next. This with the previous drawing, will make a total repayment of £51,000, leaving a balance of £99,000 on the first issue of debentures.

Submarine Cables Trust.—The report of the trustees of the Submarine Cables Trust for the financial year to April 15 states that the revenue, including the balance brought forward, amounted to £16,044. They regret that the Atlantic cables competition referred to at the last annual meeting of the certificate holders continues, and that, in consequence of the small return from their investment in Anglo-American Telegraph stock, they are unable to meet the coupons of the trust in full as they become due. The balance of £1,10s., which was left outstanding on the coupons due on April 15, 1887, was paid on October 15 last and the coupons which became due on October 15, 1887, were liquidated on April 16 last. The expenses of the trust since the payments on account of the coupons amounted together to £16,596 leaving £1,448 to be carried forward. The balance is equal to 8s. 6d. per cent., which the trustees propose to pay to the certificate holders, with a further amount to be taken from the current year's revenue, as soon as they have sufficient available funds to make a substantial payment on account of the overdue April coupons.

NOTES.

Electric Lighting Bill.—The Amendment Act to the 1882 Bill was read for the second time in the House of Commons on Tuesday evening, May 8th.

Incandescent Lamps. Incandescent lamps of 500 and 1,000 c.p. are said to be replacing the Lucigen light, hitherto used where extensive outdoor lighting is required.

Book Received. "Principles of Dynamo-Electric Machines, and Practical Directions for Designing and Constructing Dynamos," by Carl Hering (W. J. Johnston, New York.)

Society of Arts. A paper on Electric Lighting for Central Stations will be read by Mr. R. E. B. Crompton at the Wednesday evening meeting of the Society of Arts. The Attorney-General will preside.

Personal Honours. Among the personal honours with the distribution of which the Emperor Frederick of Germany has marked the opening of his reign, Dr. Werner Siemens has been ennobled and dignified with the prefix "Von" to his name.

The Largest Installation.—New Orleans, La., claims to have the largest electric light plant in the world. The power is furnished by two engines, with a capacity of 1,200 h.p. There are 1,500 arc lamps in use in that city operated by the plant.

Thermo Batteries.—A thermo-electric couple has been constructed by M. Heime, a French electrician, which has an E.M.F. of 0.18 volt, and a resistance of 0.009 ohm. This is a great advance over anything hitherto attained in thermo-electric couples.

Melbourne.—The Australasian Electric Power, Light, and Storage Company has obtained the principal contract for lighting the forthcoming Melbourne Exhibition. It is expected that Messrs. Ganz and Co., of Buda-Pesth, will obtain the contract for the annexes.

Smoke Consuming by Electricity.—A Vienna engineer has just taken out a patent for a new smoke-abating process. By means of electricity he proposes to condense the solid part of the smoke as it rises from the coal, the carbon thus formed falling back into the furnace.

Telegraphs and Railways.—According to a statement of the Postmaster General, there are nearly 1,600 railway stations open for telegraphic business. During hours fixed by the companies, and in cases of emergency, telegrams can be sent at other times and from other stations.

Electrical Homoeopathy. If your watch has been magnetised by a continuous current dynamo, then according to Mr. Lange—it may be cured by placing it within a helix in connection with an alternating current machine—to which process *Electrotheria* applies the above term. *Similia similibus curantur.*

Waterford.—The electric light is extending in Waterford, Ireland. It is intended to lay on a new service, supplied by meter, at ½d. per hour for 8 c.p. lamp, ¾d. for 16 c.p. lamps, making the cost equal to gas at 4s. per 1,000. The supply is to be on from sunset to sunrise, and to be laid on ready for next autumn.

A Trust Company.—Rumours come from Philadelphia that a syndicate with unlimited capital has been formed in New York and Boston to consolidate all the electric lighting companies in the great centres of the

United States in a trust, so as entirely to control the electric lighting industry.

Electric Railroads in the States.—An electric street railroad will be built at Bristol, Tennessee, and a short electric railroad will be built by the East Land Company, of Birmingham, Alabama; and the latter city is going in for a central lighting station. The new Bristolians and Brummagemites are ahead of the old.

Telephone Extension. The Hearn Local Board has decided to charge 5s. to the National Telephone Company, who asked permission to erect a line of telephone poles through the Hearn district, for the purpose of establishing telephonic communication between Nottingham, Sutton, Chesterfield, and Sheffield, *via* Alfreton.

Electric Tempering. Electricity has been found useful in tempering watchsprings, greater accuracy as well as ease of manipulation being by its means obtainable. The spring is attached to a holder communicating to a suitable source of electricity, plunged in oil and heated to any degree of temperature while under the surface, and cooled with any degree of slowness.

Exhibition in Glogau. At the suggestion of the Glogau (Lower Silesia) Industrial Association, in union with a large number of other industrial associations, an exhibition of small motors for hand work, industry, and agriculture will be held at Glogau from the 3rd to the 18th July. With this exhibition will be combined an exhibition of machine tools, electric lighting apparatus, &c.

Universal Electricity. *Fire and Water* says—"Of course, it is looking pretty far ahead to imagine a city with a system for distributing electric power, as complete as that of the present system of water works, in every street of which an engine could take power with the same readiness with which it now obtains water. Much more wonderful results than this have, however, been accomplished within the memory even of children.

Leamington. Mr. Crowther Davies has given notice that, at the next Council meeting, he will give notice that the Town Clerk give twelve months' notice to terminate the contract for electric lighting. The Leamington lighters should look to their laurels. We believe the agitation that has been so violent against the new illuminant is destined to fail; but at the same time every effort should be made to obtain a thoroughly satisfactory and steady light.

New Electrical Governor.—An electrical governor has been patented by Mr. Frank E. Prichard, of Cedar Falls, Iowa. It is designed to control the speed of water-wheels and other motors by means of an electric current, a ratchet-wheel being connected with the valve or gate, engaging an oscillating lever carrying pawls, in connection with electro-magnetic mechanism for controlling the pawls, and a centrifugal governor for connecting the current.

Electric Alarms.—The Denison Hall Manufacturing Company, of Chicago, are introducing a neat electric alarm clock. The alarm mechanism is a small electric bell, which can be set to ring for five minutes or until stopped. The clock and the battery are enclosed in one case. It is coming greatly into use for waking railway men, and the alarm not requiring winding, recommends it for use in many cases for which persons would not trouble to wind up a spring.

New Storage Plates.—Mr. Chas. D. P. Gibson, of New York, has designed a new method of placing the active material in plates of storage batteries. The material

is placed in capsules, which are then put into holes in the plates, and the plates are then passed between rollers which compress the capsules endwise, and fasten them in the plates. The ends of the capsules are perforated to allow the air to pass out when the paste is put in, and to allow the electrolyte to enter when they are in position.

The Telegraph of the Future.—Mr. Patey, permanent secretary of the telegraph department of the Post Office, in giving evidence before the Select Committee of the House of Commons, on Tuesday, on the Revenue Department's Estimates, stated that in the course of years the department must look to a great expenditure on underground wires, not in substitution of the overground system, but in addition to it. The present cost of annual extension of telegraphs was about £100,000 a year; but the laying down of the first underground wire would cost ten times as much, and each succeeding underground wire would *per se* cost more than one overground wire.

Accumulators.—Any information about the efficiency and lasting powers of accumulators is of interest, and especially so at the present time, when a good deal of discussion has been carried on between the advocates of transformers and accumulators for lighting purposes. We notice that the Metropolitan Telephone and Telegraph Company, of New York, installed a set of 600 accumulators in the spring of 1887. These accumulators have been used to supply the current for 500 incandescent lamps, and give an efficiency of 80 per cent. Mr. Seely, the electrician in charge, is so well satisfied with the accumulators that he intends using 300 of these cells for working the telegraph instruments.

Finance. I hear on the best authority that a few days ago one of the largest individual holders of shares in various gas companies disposed of the whole of his shares, and has re-invested the proceeds in certain electric lighting undertakings. Whether he is right or wrong remains to be seen; but judging by what has recently come under my notice, I would not care to invest much money in gas shares at present prices. Putting electricity on one side altogether, investors in gas companies should not overlook the fact that the petroleum industry is rapidly coming to the front. The race between electricity, gas, and oil will before long be an exciting one, and, if properly handled, electricity should win.—*The Lighthouse.*

Electric Light for Berlin.—According to the *Electrotechnische Zeitschrift*, the Anglo-American Brush Corporation are laying before the authorities in Berlin, through the Thüringer Bergbaugewerkschaft of Berlin, a contract for street lighting, according to which the aforesaid Company will undertake the lighting of some of the principal streets and squares of Berlin, by means of 150 Brush arc lamps, driven by four 40-light Brush machines. They will be arranged in four circuits, the cables to be laid underground in Callender's bitumen. Part of the lamps are to run all night, the remainder till midnight. The town pays a rental of 30 pfennig (3½d.) per lamp-hour, which, at 396,837 lamp-hours, gives a cost of 119,051 marks (about £5,800). The town pays for its own lamp-posts.

School of Electrical Engineering.—A very satisfactory report has just been received by the managers from the external examiner, H. R. Kempe, Esq., of the G.P.O., showing that out of 14 students of the advanced class who went in for the final examination held on April 18, in which 70 per cent. of the marks is required, 8 obtained the vellum certificate with the following percentages:—H. F. S. Crawford, 94·6; A. H. French, 88·6; T. W. Watts,

88; A. O. Jensen, 87·3; H. A. McCausland, 86; E. L. Simpson, 85·3; E. H. Greg, 80·6; A. E. Beddoe, 71·3. About two months ago, as the result of an examination in engineering, the following students also obtained the vellum certificate: L. M. Green, 97·3; H. E. Taylor, 97·3; P. T. Heath, 90·6; H. A. Irvine, 88·6; R. Cotton, 87·3.

Value of c .—The ratio c between the absolute electromagnetic and electrostatic units of quantity has been recently determined by M. Himstedt by means of Maxwell's condenser method. The mean value obtained in fourteen experiments, giving very concordant results, was—

$$c = 3.0074 \times 10^{10} \text{ centims. per sec.}$$

This value is lower than that obtained by Weber and Kohlrausch (3.1074×10^{10}), but higher than those obtained by Sir W. Thomson (2.825×10^{10}), Clerk-Maxwell (2.88×10^{10}), Ayrton and Perry (2.98×10^{10}), and Gordon (2.9857×10^{10}). It approximates closely to that obtained by Cornu viz.: (3.004×10^{10}). All these determinations differ but little from the velocity of light in vacuo, which, according to Foucault's determination, is 2.98×10^{10} .

New Electric Motor for Trams.—A motor of novel design has been made by the "Helios" Electrical Company, of Ehrenfeld and Cologne, to overcome the difficulty experienced in starting cars. The motor has field-magnets connected with the wheels of the car; the armature revolves loosely on the same shaft, but its revolution can be checked by a brake, when the field magnets begin to revolve, driving the car. The driving wheels have also a brake, which is connected with that previously mentioned, so that by taking the brake off the armature the brake on the driving-wheel is put on, and *vice versa*. The motor is started at full speed, allowing the armature to revolve; as its motion is gradually stopped by the brake, the motion of the brake handle releases that of the driving-wheels, which gradually revolve faster as the armature stops.

Technical Education in India.—Mr. Alfred Chatterton, B.Sc., has been appointed professor of engineering to the college at Madras. The selection was entrusted to a committee appointed by the Secretary of State for India, consisting of Sir Alexander Taylor, Prof. Unwin, and Sir Philip Magnus, who recommended two gentlemen, and of these Mr. Chatterton has been chosen. Mr. Chatterton was educated at St. Mary's College, Peckham, and subsequently studied at Finsbury Technical College, where he gained the Clothworkers' exhibition and numerous medals, and has since taken his London degree. Mr. Chatterton has gained his practical knowledge at the locomotive works of the London and South Western Railway Company at Nine Elms, where he has also been engaged in teaching the evening classes for apprentices. The Finsbury men are beginning to be appreciated.

The Writing Telegraph.—The promoters of the latest system of writing telegraphs are largely endowed with Yankee persistency, and members of Parliament, of course actuated by the purest designs, somehow or other generally seem willing to assist the promoters. It is quite clear that having purchased the telegraphs, the Government cannot from a business point of view, allow unlimited competition. The telephonic competition will have to be bought up, and one such purchase is enough even for England during each decade. The Postmaster-General, replying to Mr. M. Ewan, said if there is a substantial demand for the establishment of exchanges to be worked by the instruments of the Writing Telegraph Company, it would be preferable that

they should be in the hands of the Post Office, the instruments being supplied by the proprietors on terms to be arranged. We do not for one moment anticipate that any such demand is possible. A writing telegraph is not wanted for ordinary work, and the exceptional work is far too scarce to justify any expenditure in fitting up the system.

Brussels.—A prize of £10 is offered by the Belgian Society of Electricians for the best elementary essay on the principles of electricity, for use by persons of ordinary education engaged in electrical pursuits. Simplicity and clearness are the essential qualities: algebraic formulæ are only admitted in appendices. Demonstration of the laws need not be attempted as a rule. Magnetism need be treated only so far as necessary for comprehension of electro-magnetism. The offer is open to the world, but the essay must be written in French. The author preserves his copyright, but it is to be first published in the Bulletin of the Société. Manuscripts must be written on one side of the paper only, and must bear a motto or *nom-de-plume*, accompanied with a sealed letter bearing name and address of author, and must be addressed, before January 1st, 1889, to M. Bode, President de la Société Belge d'Electriciens, 37, rue Philippe le Bon, Brussels. Further particulars can be obtained of M. E. Lagrange, Secrétaire de la Société, 26, rue Vilain XIII., Brussels.

Electric Fire Alarm. A very simple apparatus for indicating a rise of temperature in any portion of a building has been devised by M. Pian. The essential part is a glass globe, the neck of which is closed by a membrane which, by the expansion of the contained air, is made to close the circuit of a battery and bell. The apparatus is regulated by means of a screw, carrying one of the platinum points brought into contact by the inflation of the membrane; the other platinum point being attached to a spring in close proximity to the membrane. In order to render the instrument independent of barometric and ordinary temperature variations, it has been found advisable to establish a communication, by means of a minute orifice, between the enclosed air and the surrounding atmosphere. By means of this device only sudden variations of pressure, such as would be due to a current of heated air arising from combustion, are indicated. The apparatus should be placed at a considerable altitude above the floor; and we think that the objection of fragility might require to be obviated by the use of a globe or other vessel of copper, in lieu of one of glass.

Miner's Lamps.—At a meeting of the members of the North Staffordshire Mining Institute at Stoke-on Trent last week, Mr. J. W. Swan read a paper on the "Edison-Swan's Electric Miners' Safety Lamp," which was described and illustrated in our issue of January 20. Numerous questions were put to Mr. Swan on the subject, and it was explained that the principal points aimed at in the lamp were safety and abundance of light, the size of the lamp not necessarily being a fixed one. An arrangement had been designed, and could be applied to a portion of the lamps, to indicate the presence of gas, and another arrangement, which might be used in conjunction with the electric lamp or independently, was shown for testing the percentage of gas in a mine.—At the Astley Institute, Dukinfield, Mr. Oswald R. Swete, electrician to the New Portable Electric Lamp and Power Syndicate, read a paper on "Lighting Mines by Electricity." Mr. A. C. Boyd, J.P., occupied the chair, and after the reading of the paper, which dealt in a popular manner with the history of the lighting of mines,

the construction and working of the portable lamp put forward by the syndicate, and the advantages of flameless illumination in the case more particularly of mines, questions were asked by several of the miners present, and were answered by Mr. Swete. The meeting concluded with a vote of thanks to Mr. Swete and to Mr. Nicholson, one of the directors of the syndicate.

Wire-covering Machinery.—The price-list of Messrs. Thomas Barraclough and Co., Manchester, contains a very comprehensive list of improved and new machinery for covering, stranding, and sheathing electric wires and cables. Types A to D are yarn-winding machines; E to J, vertical and horizontal machines for covering electric wires with silk, cotton, jute, &c., for sizes 5 to 32 B.W.G., and with tanks for compound if necessary; K and K₁ are for very fine wires, constructed to run at the highest speed the material will stand. The braiding machines are made in two patterns—for floor or for bench, and present two important advantages: (a) they can be run at a high speed; (b) they are furnished with large carriers, so as to run a considerable time before stopping to replace the bobbins. Several lately patented inventions are introduced: for instance, all the machines, except the smaller sizes, are furnished with adjustable feed or draw through apparatus, so as to regulate, by means of gearing, with the greatest nicety, the speed at which the braided wire is drawn out, thus causing the covering material to be applied to the wire with the exact degree of density required. They are also constructed with a weight to each carrier, so that in case of a strand breaking, the machine stops automatically, preventing imperfect work. Taping, tarring, wire-winding, and cabling machines are also included, and machines for sheathing shore ends of cables.

Accumulators for Tramways.—Before the *Société Electrochimique* of Vienna, Baron Roman Gostkowski discussed the advantage of the employment of accumulators for tramways, and pointed out the reasons which should lead to the substitution of other motive forces to that of traction of horses. For increase of profits it is necessary either to increase the receipts or reduce the cost. The first can be obtained by increasing the speed of travel, the second by use of cheaper motive power. If the speed is to be increased, the resistance to traction must be diminished, or greater power employed. The speaker gave some interesting information upon the best relation of tare to net weight in vehicles, and pointed out that the best result was obtained when they were as 1 to 1. With regard to augmentation of force, he showed it was impossible to expect this from horses, they already being worked beyond normal power. It is, therefore, necessary to employ other motors. In comparing steam engines (which are too heavy), compressed air (which take too much room), and other motors, he came to the conclusion that the best form was an electric motor, fed with accumulators. He showed by calculation, and by the result of experiments made with accumulators, that in using this power a much greater speed can be obtained than with horses, the cost being about the same. He ended by expressing the view that this mode of traction would soon be adopted in Vienna.

Trouve Motors for Pleasure Boats.—The *Revue Internationale* gives an abstract of a paper by M. Trouve read before the Association Française pour l'Avancement des Sciences, at Toulouse, in which he describes various apparatus he has perfected for the application of small electric motors to pleasure boats, which he thinks will be

adopted on a large scale. The inventions consist of a light and powerful motor, a new method of construction of the propeller, a commutator for forward, backward, or change of motion, signal of alarm, or electric siren, as well as a powerful signal light for avoiding collisions. The inventor points out that it is well known that a steam boat will not easily run a clear distance of 3,000 miles, whereas with electricity, even in its present development (while the steam engine is at its greatest development), double the distance is easily run. M. Trouve, before terminating, called particular attention to his latest inventions:

(1) A very small electric motor, extremely light (0.2lb.), which, furnished with an air-screw, and set in motion by a current, could raise itself into the air; (2) an interrupter, for currents of high tension, to suppress sparking; (3) an electric Auxanoscope, for projecting the images of opaque bodies under conditions of extreme simplicity. M. Trouve projected the portraits of MM. Chevreul and Pasteur. These most successful were of pieces of money, and, above all, of a watch in motion. M. Trouve also showed many applications of the electric light to the work of naturalists, chemists, and microscopists.

Simple Arc Regulator.—The *Comptes-rendus* has received a description of a new and simple regulator for arc lamps, designed by M. Charles Pollak, depending for its action upon the lengthening of a wire under the heating action of the electric current. The current is led to each carbon by a brass wire sufficiently thin (0.45 millims.) to be sensibly heated by the current, and kept tightly stretched by a spring. This spring, also of brass wire, is twisted in the form of a helix, and so disposed as to form at the same time a tension spring, a multiplying lever arm, and the carbon holder. The second carbon is fixed in like manner, the apparatus being symmetrical. The carbons, at first, are in contact until the circuit is closed, when the straight wires stretch and the carbons separate. The arc being formed, the resistance it introduces limits the heating of the straight wires, and therefore the length of the arc remains constant. As the carbons burn away, the increase of resistance which results causes a decrease in the lengthening by the heat, and therefore a corresponding adjustment of the carbons. The apparatus thus constructed regulates the electric arc for a period of three hours. It relights automatically; its action is regular and satisfactory. It is necessary to add, however, that by its construction, the strength of current, and therefore of luminosity, gradually increases somewhat during action. Such a regulator will be serviceable by reason of its extreme simplicity, no mechanism nor electro-magnets being necessary. All that is required to make it is a piece of board and four pieces of brass wire. This lamp seems to indicate a new departure in regulation, but it is doubtful whether the lamp described has much practical value.

Improved Electrical Speed Indicator. A simple device by which the increase or diminution of speed in machinery above or below its normal rate may be indicated electrically has been patented by Mr. Frederick W. Schlegel, of 20, Ashton-street, Charleston, South Carolina. The indicator shaft, arranged to receive motion conveniently from the machine whose speed is to be indicated, is formed of two parts connected together by an insulating sleeve, and is journaled in a frame whose upper and lower parts are connected by a threaded insulating sleeve, binding posts, connected with an electric bell or alarm, being secured to the lower and upper parts of the frame. In grooves on opposite sides of

the indicator shaft are secured flat springs, with a weight, preferably of spherical form, on the outer extremity of each spring, a nut being fitted to move up or down on the shaft to vary the length of the free ends of the spring arms. The weights are adjusted relative to the motion of the indicator shaft when driven by a machine, so that when the machine runs at its normal speed the weights will revolve in a position between the upper part of the shaft and the contact screws on either side. When the speed of the machine increases, so that the weights touch the contact screws, the circuit is completed and an alarm is given, a like effect being also produced when the machine runs slower than its normal speed, or when it stops, as the weights are then brought into contact with the upper part of the indicator shaft, thus completing the circuit. The indicator may be adjusted to adapt it to higher or lower speeds by turning the nut on the lower portion of the indicator shaft, thus shortening or lengthening the spring arms, and also by turning the contact screws in or out.

Scientific Industries. Lord Thurlow, F.R.S., presided on Tuesday night at a house dinner of the City Liberal Club, Walbrook. *The Times* reports among those present Dr. Silvanus P. Thompson, Mr. David Chadwick, Mr. J. W. Swan, Sir Douglas Galton, K.C.B., F.R.S., Admiral Bythsea, C.B., V.C.; the Rev. William Windle, Mr. E. Rider Cook, Mr. J. I. Courtenay, Mr. A. H. Renshaw, Mr. William Westgarth, Sir J. H. Johnson, Mr. John Pound, Sir John Bennet, and Mr. T. W. Deverell (the secretary). The speeches made related entirely to science as applied to industrial purposes. After the reception of the usual loyal and patriotic toasts, the Chairman proposed the toast of the evening, "Scientific Industries." It seemed to him, he said, that there was no place within Her Majesty's dominions where such a subject should find such ready acceptance as in the heart of London, when they considered what London was to-day, and the extraordinary conditions in which our daily life was continued. Referring to the electric light, one of the scientific industries with which he was personally acquainted, he expressed his conviction that it would infallibly, sooner or later, take its place as the universal lighting agency of this great city. He concluded by coupling with the toast the names of Mr. Swan and Dr. Silvanus Thompson. Mr. Swan reminded them that as an established industry the electric light was barely eight years old. In England it had two great difficulties to contend against—very good and cheap gas and the Act of 1882. Thanks to the persistence of Lord Thurlow, the obnoxious features of the Act appeared as if they were about to be swept away; and with regard to cheap gas they must fight it as best they could. The electric light had advantages over gas in purity and safety, and on the score of cheapness alone it could in some cases beat gas. He had every hope that before long the electric light would be brought within the reach of every one by the establishment of stations. Dr. Silvanus Thompson said he could not help thinking that, so soon as the Electric Lighting Act was amended, there would be a very great development of arc lighting. Though not behind the United States and the rest of Europe in regard to electric lighting, we are very far behind the United States in the development of the electric telephone. He proceeded to show that in other branches of science great progress had been made of recent years. When we had overhead railways, we should not be content to have the trains driven by means of ropes. Mr. David Chadwick

proposed the toast of "Railways and Commerce," to which Sir Douglas Galton replied.

Motor for Submarine Boat.—The *Revue Internationale* gives the result of some trials of a motor fed by accumulators for a submarine boat, commissioned by the *Ministre de la Marine* of France, now nearly completed. The tests were carried out on land. The principal motor, which is to actuate a screw of 5ft. diameter, has sixteen poles, disposed symmetrically round a movable ring, 3ft. diameter. It is furnished with four brushes, two for forward and two for backward running. The motor is to furnish 52 h.p., calculated at a normal current of 200 amperes, at 192 volts. The source of electricity is a battery of 564 accumulators, each weighing 38lb., with alkaline solution, constructed by Messrs. Commelin, Desmazures, et Bailliehauche. These are grouped in four different ways, so as to obtain, by means of a special switch, four different speeds by movement of a handle. The first group, slowest speed, consists of twelve groups of 47; the second, medium speed, six groups of 94; the third, ordinary speed, four groups of 141; the fourth, quickest speed, two groups of 282. The Commission appointed by the Minister went, on March 16 last, to Havre, to the works of the *Société des Forges et Chantiers*, who have built the machine. The motor being fixed, the screw was replaced with a water turbine to oppose an equal resistance to that of the screw. The accumulators had been charged, grouped in the third manner, with a current of 100 amperes, with a difference of pressure of 140 volts at the terminals. The length of charge was 23 hours; the pressure varied from 135 at the beginning to 144 volts at the end. The charging was prolonged beyond the time necessary, because many of the accumulators were charged for the first time. The total capacity of each accumulator resulting from the weight of zinc contained in it, is 520 ampere-hours. The quantity of electricity supplied in the charging current was 575 ampere-hours. The discharge was arranged with the fourth grouping, quickest speed. It lasted four hours and a half, giving 58 h.p. for the first three hours (206 amperes and 200 volts); 54 h.p. for the fourth hour (200 amperes and 200 volts). At the end of four and a half hours the power fell to 47 h.p. (190 amperes and 183 volts), but a part ($\frac{1}{10}$) of the accumulators discharged themselves by reason of insufficient insulation. In spite of these unfavourable conditions, the discharge of 4½ hours had utilised $450 \div 520 = 0.863$ of the total capacity of the accumulators. Taking into account the difference of potential between charge and discharge as 1 to 0.75, the return of energy was $0.863 \times 0.75 = 0.65$ of energy produced. Under these conditions the weight of accumulators, case, and liquid is 81lb. per h.p. returned. The next day, without recharge, the accumulators gave several hours' work, at different speeds, for testing the change of speed of the motor. The resistance of the motor is 0.16 ohm, greatest speed 280 revolutions per minute, with a current of 200 to 210 amperes. The field-magnets (mean field 3,000 C.G.S. units) attained a temperature of 40deg. centigrade, after 4½ hours running at greatest speed.

Royal Society Soiree.—The first annual soiree of the season was held on Wednesday evening at the rooms of the Royal Society, Burlington House, when the fellows and guests were received by the President, Prof. Stokes, M.P. The Royal Society holds two annual soirees, one in May and the second in June. From a scientific point of view the former is by far the more important of the two. At it the

leading workers in science produce, for public inspection, what we may call the *pièces justificatives* of the new discoveries and new theories which have been brought forward during the year. Among the most interesting exhibits were those of Mr. Norman Lockyer, to illustrate his theories relating to meteoric streams. Mr. Eric Stuart Bruce exhibited his electrical translucent balloon for flashing signals at night. The utility of such an arrangement in naval and military operations is obvious, and to judge from the experiments last night, Mr. Bruce's balloon ought to be efficient. The apparatus consists of a captive balloon made of perfectly translucent material, having several incandescent electric lamps ingeniously supported inside, a metallic circuit connecting the lamps with a source of electrical power on the ground. Mr. Shelford Bidwell showed his apparatus for measuring the changes produced by magnetisation in the dimensions of rods and rings of iron, cobalt, nickel, bismuth, and other metals, and this instrument is so delicate that it will measure changes of length to the 25,000,000th of an inch. The effects of magnetisation in the contraction and expansion of the rods, as shown by the apparatus, are very curious. Two sets of miners' electric safety lamps were shown in the library. One of them, exhibited by the Edison and Swan Company, is only 7in. by 4½in., and weighs about 7lb. The Schanschieff Electric Light and Power Company showed another lamp in various forms according to power and duration of light; and these seemed to be really of practical utility and as safe as could be expected. One of the most delicate pieces of apparatus shown was Mr. C. V. Boys's radiometer, probably the most delicate instrument for measuring heat yet made. It consists of a circuit made of antimony, bismuth and copper hung in a magnetic field by a fibre of quartz so fine, that if magnified to 20 times its size, it would still be finer than spun glass. Since last year Mr. Boys has introduced improvements which render the apparatus almost perfect. Equally delicate were Mr. Boys's experiments with soap bubbles. A good deal can be done to soap bubbles without injuring them. At the same time an extremely slight electric influence brought near a pair of bubbles made them run into each other. In the same room where these were shown the Meteorological Society had a fine exhibit, consisting of a series of many photographs of flashes of lightning, which were highly instructive when compared with a neighbouring exhibit of three diagrams of lightning made by James Nasmyth in 1858, showing (1) Nature's lightning; (2) painter's lightning; (3) forked lightning. One exhibit, not only of great beauty, but having important practical bearings with reference to the present inquiry as to the decay of water-colours, was the elaborate apparatus of Captain Abney and General Festing for measuring the light reflected from coloured pigments. The powerful electrical influence machine of Mr. James Wimshurst was also exhibited, which, with Leyden jars, gives a spark 13½in. long. A somewhat similar machine was used by Dr. Marret in the meeting room for illustrating on the screen flashes of lightning of various kinds. Robertson's writing telegraph naturally excited great astonishment, not only by its admirable performances, but by the simplicity with which it is worked, though some seemed to think it would add one more terror to life. The holophotometer exhibited by Woodhouse, Rawson and Co. is a marvellous apparatus, of great ingenuity, for measuring, by a careful adjustment of mirrors, the intensity of light all round. The rooms were brilliantly lit up by the electric light.

DOUBLE AND SINGLE EARTH WIRE SYSTEMS FOR ELECTRIC LIGHTING.

BY J. D. F. ANDREWS.

During the seven or eight years that the illumination of buildings has been possible by means of the glow lamp, the development of the system of wiring has made exceedingly slow progress towards that state of simplicity and universal sameness that gas now holds. We can attribute this backwardness to many causes. The difficulty of having to deal with two conductors instead of only one is greatly in the way, and the influence of some insurance companies, who insist upon a compliance with certain rules, may have had a retarding effect, but most conspicuous amongst the influences is the fact of many contractors taking advantage of a flimsy nature of construction that electric light fittings and appurtenances are so easily adapted to, with a view to reduction of cost, regardless of durability and system.

One of the objects of the following article is to explain the results of some experience in the system now generally known as the single wire system, which would be more correctly called the earth system. The earth system has now been applied to a large number of installations, mainly at sea, but also to some on land. The main points of difference with the double wire systems are shown diagrammatically in Figs. 1 and 2. The current, Fig. 1 (which represents the double wire system), is supposed to leave the dynamo by the black wire, pass through the fuses, F, to the lamp, back by the red wire (shown dotted), through the fuses to the dynamo. It is essential in the double wire system that there should be fuses on both wires, so as to prevent as far as possible the danger from a short circuit, which can be brought

Fig. 1.

about through the medium of such outside conductors as the hull of a ship, or the gas and water pipes of a building, in the following manner. After the installation has been running some time, a connection might get made between one of the wires and, say, a gas pipe. It is not a fault that will make any difference to the light, and it may, and would, most likely, not be discovered until something else happens. Supposing the connection above referred to, to be at A, Fig. 1, and that later on another connection is made at B, on the opposite wire, it is evident that now the iron pipe short-circuits the two wires, and if there were not fuses on both wires, the single light wire, A, would doubtless get very hot before the main fuse melted. But the fault might be worse still. Supposing fuses only to be on the lead, none on the dotted wire, the second earth-connection might be in the dynamo at C; in this case all the fuses would be beyond the short circuit, and the consequence very serious. Of course, with fuses on both wires, as shown in the figure, such accidents are provided against.

It is, however, possible to provide against such accidents without double pole fuses, and thus greatly reduce the danger of fire from this source. This alternative is to connect one of the wires to earth on a main water or gas pipe, as shown in Fig. 2, which illustrates the earth system. It is obvious that fuses would be unnecessary on the earth or return wire, and with fuses properly distributed and adjusted over the leading wire no short-circuit could exist, and if an earth connection took place in the dynamo, the danger would be confined to the machine.

It might be said that the insulation of the machine is more liable to break down through the earth connection. This, however, has not been found to be the case in practice, and the explanation is that while there is full pressure between the body of the machine and the wire at one terminal, there is no pressure at the other. Whereas when

the body of the dynamo is insulated from both terminals, the pressure between the body and either terminal is half the total pressure, but the whole dynamo is exposed to this pressure. The strength of this argument lies in the fact that the quantity of electricity in electric lighting is out of all proportion to the pressure.

For reasons very similar to the above, it is not necessary to increase the insulation of the leading wires, but there are also other points to consider. In the double system two faults can happen—a connection to earth, and a direct short circuit to the opposite wire; the pressure to earth from either mains being half the total, if both wires are equally insulated. In the earth system there is only one fault that can happen, namely, the connection of the lead to the earth wire or earth; and although there is the total pressure between the wire and earth, there is only half the length of wire. At all points where the insulation of the wire is critically exposed, the conditions with the earth system are much more favourable for preserving it. For instance, in the fittings the leading wire has the whole space at its disposal; that in the double system would be for two wires in passing down the centre of the tube. Usually with the earth system this central wire is heavier insulated, and is much larger in section than is required for the current, so as to be rigid within the fitting, to prevent continued vibration and contracting and expanding, destroying the insulation, as has often occurred in both systems; and by using a wire of large practical size the parts of the fittings can be wired separately and screwed together with butt contacts. The fittings are, of course, all connected to the earth return wire. In the event of a building lighted electrically being struck by lightning, an

Fig. 2.

earth connection to one of the leads would be a great preservative, whereas the double system would be like a bad lightning conductor, worse than none. In view of the rapidly extending overhead wire mains for electric light, the earth system should find great encouragement as a protection against the effects of lightning.

With the reserve due to want of experience we may say that also with transformers the earth system is a safe protection from lightning, even supposing the primary circuit to be double wired to guard against induction in other wires. The transformers can be protected by a lightning protector, or it may be the lightning protector itself. The protection would be definite and known, whereas the only lightning protection under the present arrangement is the dynamo producing the current, which has already, on some occasions, been known to play its part in this function. Although induction in telephone wires is a reason that might prevent an earth connection being adopted with transformers in both primary and secondary circuits, yet the many advantages of the earth connection may bring about its adoption notwithstanding. In the event of concentric wires, such as previously described, being employed, and these buried in the earth, it will doubtless be necessary to connect the outer sheathing to earth plates at intervals to prevent electrolytic action between one section and another destroying the sheathing. The action would be transferred to the earth plates, which might consequently require to be renewed at long intervals. Of course other means could be employed to preserve the sheathing or outer conductor, although none would have the special advantage of reducing the resistance of the return circuit that the earth plates introduce.

Another point where the insulation of wires is exposed is at the fuses. In the double wire system the fuses of each wire, to be practical, must be near each other, and conse-

the opposite sides of the circuit are exposed in close contact. In the earth system, however, only the lead to the fuse box, and there is consequently no such risk.

In reference to the fuses themselves, there are several reasons why it is advantageous to reduce their size as is effected by the earth system. It is well known that arcs from metal joints can be stretched to a considerable length—two or three inches with 100 volts under certain circumstances—and the arc often continues an appreciable time after the fuse has melted. If a fuse is made of lead or copper wire, it is often red hot long after it melts.

Fig. 3

The chief danger of producing fire through electric light is not a dead short circuit, but a partial short circuit, or an opening circuit. A partial short circuit is an arc between the two wires or some other cross connection that increases the current sufficiently to melt the fuses, and therefore a provision for safety, but may or may not be effective.

Against opening circuits, through corroding wires getting stretched and broken, there is no protection in the ordinary system of wiring; this fault is therefore the most dangerous, and not the least frequent. The single-plate system stands to advantage in this respect, on board ship, there being only about half the length of such faults to appear in.

Curious instances have come under the writer's eye of opening circuit faults. One case, in a ship, water leaked into a groove with one of the wires, which was covered with pure rubber, cotton serving and braided. Water penetrated this insulation, and the electric current passed through the water to a more distant part of the wire, carrying with it electrolytically some of the insulation of the wire, depositing it on the outside of the insulation three or four yards distant. In another instance an opening circuit on board ship was observed to be caused by an electric light wire casing, and on removing

Fig. 4

a dull red glow about 6 in. long was observed in the insulation occupied by one of the wires. The wire had apparently broken, and an arc formed, which gradually spread the ends wider apart, and the current found passage through the charred wood.

Though it is impossible to entirely prevent opening circuits, their danger can be minimised by causing them to be short circuits, and thus come under the protection of fuses or cut outs. This means running the wires so close together that any heat in one would act upon the other and produce a short circuit. Such is the theory, but the practical carrying out of such an arrangement, and must be made against the possibility of

only a partial short circuit. The different points of this case are well met in a system of sheathed wiring designed by the writer some years ago, and now in extensive use on shipboard. The illustrations (Figs. 3 and 4) show the system as now constructed by Messrs. Muir, Mason, and Coulson, Glasgow; it is essentially earth wiring, the leading wire, which is insulated with vulcanised rubber, being surrounded with a sheathing of iron wires which form the return. An open or opening circuit is an almost unheard-of thing with this wiring, but should it take place a short circuit and the melting of a fuse are the immediate result. A partial short circuit is also a circumstance almost inconceivable with such a system. And notwithstanding that every fault results in a short circuit, experience has proven that short circuits are less numerous than with the ordinary wiring, which is attributable to the great protection of the sheathing. The switches and fuses are arranged in cast-iron boxes resembling the joint boxes, and are placed invariably together, and only at the junction of a sub-main with a main. Usually a sub-main is arranged to supply only 12 lamps 100 volts, in which case the smallest branch wire is No. 15 S.W.G.; it being calculated that this size will carry without danger of fire the current that will melt the fuse. If the sub mains, and consequently one switch and fuse, have to carry more than eight amperes, the smallest wire must be chosen larger in correspondence to the current. For 30 100-volt lamps the smallest wire is No. 12 S.W.G.

THE LATE SIR CHARLES T. BRIGHT.

We regret to announce the death of Sir Charles Bright, immediate Past-President of the Society of Telegraph-Engineers, who may be considered as one of the founders of the first Atlantic telegraph, in connection with which enterprise his name is chiefly familiar to the public, and who is known also as having been engaged in the development of telegraphic communication from its early stages up to the present time. We cannot do better than follow the *Times* in its notice, although, perhaps, the completest record of the late Sir Charles Bright's work will be found in a biographical notice which appeared in our own columns in the issue of July, 1883. Charles Tilston Bright was born in 1832, the youngest son of the late Mr. Brailsford Bright, the head of an old Yorkshire family long settled in Hallamshire. Charles Bright was educated at the Merchant Taylors' School, and from his schoolboy days he turned his attention to electricity and chemistry. He was, from the age of fifteen, engaged with the Electric Telegraph Company, and worked for some years under Sir William Fothergill Cooke in introducing and developing telegraphs for the public service. Among his services in this regard, it may be mentioned that he was occupied in the establishment of telegraph stations on several lines in the North of England and in Scotland. On one occasion this was before he came to the age of 21 he was called upon to lay underground wires in Manchester. It was essential that the traffic of so busy a city should be interrupted as little as possible. Charles Bright did not interrupt the traffic at all. In one night he had the streets up, laid the wires, and had the pavement down before the inhabitants were out of their beds in the morning. In 1852, at an age when many professional men have hardly begun their life's work, he was appointed engineer-in-chief to the Board of the Magnetic Telegraph Company, in whose service his older brother Edward had been acting as manager for some years. The two brothers worked together and patented a series of inventions in connection with telegraphic apparatus. Among these inventions were the system of testing insulated conductors to localise faults; various inventions relating to coils; the employment of a movable coil on an axis actuated by a fixed coil; the double roof shackle, the vacuum lightning protector; the translator or repeater for re-laying and re-transmitting electric currents in both directions on a single wire; the employment of a metallic riband for the protection of the insulated conductors of submarine or underground cables; the production of a varying contact with mercury proportionate to the pressure exerted upon it; a new type-

printing instrument; and a method of laying underground wires in troughs. Several other telegraphic improvements were carried out by him in the course of his life. While he was working out these inventions, he was also engaged in practical work in laying down lines in many parts of the United Kingdom, and he was the engineer who laid down the first cable which united Great Britain with Ireland. This was in 1853, and there is reason to believe that while he was prolonging the lines through Ireland he was already planning the continuation of the wire across the Atlantic. He had been experimenting for some time on the system of insulating wires in gutta percha tubes; and his experiments on a wire 2,600 miles long led him and others to the conviction that telegraphic communication with America was easy. The capital necessary for the purpose was raised, and in 1858, as engineer in chief, he successfully laid the first Atlantic cable of over 2,000 miles in length, and the work was completed in August, 1858, after eight days of work, during which the four ships engaged, which were lent by the British and United States Governments, had to bear the brunt of a violent storm in the middle of the Atlantic. After this signal service Mr. Bright was knighted by the Lord-Lieutenant of Ireland. After carrying out a few operations in submarine telegraphs in the Mediterranean and in the Baltic, he was summoned, in 1861, by the Government of India to complete the communication with Europe, which work he personally superintended and accomplished by joining Kurrachee with the northern end of the Persian Gulf. Within the next few years he superintended the laying of cables between the United States and Cuba, and united various parts of North and South America, the West Indies, and other places. In a paper read by him at the Institution of Civil Engineers in 1865, he advocated submarine telegraphs to China and Australia, and this paper, together, no doubt, with the excellence of his previous services, gained him the Telford gold medal of the institution. He was elected member of Parliament for Greenwich in 1865, and continued to represent that place for several years in the Liberal interest. In 1881 he was appointed by the Foreign Office as Commissioner, with the Earl of Crawford and others, to represent this country at the French International Exhibition, and he was in consequence nominated by the French Government an officer of the Legion of Honour. Last year, at the meeting of the Society of Telegraph Engineers and Electricians, Sir Charles Bright delivered the inaugural address, in which he dealt exhaustively with the whole subject and history of the telegraph during the past 30 years. He married, in 1853, Hannah, daughter of the late Mr. John Taylor, of Kingston upon Hull. Sir Charles Bright died on Thursday, May 3, at the residence of Mr. Edward Bright, at Abbey Wood, in Kent. The funeral took place on Monday, the first part of the service being held at St. Cuthbert's Church (opposite Sir Charles' residence), at 11 o'clock in the forenoon. A large number of friends gathered together at St. Cuthbert's, many of whom followed the remains of their late friend to Chiswick. Among those able to pay this last tribute of esteem and respect we may mention: Prince Victor Hohenlohe Schillinghurst, Sir Robert Jardine, Sir David Salomons, Sir Frederick Goldsmid, Prof. Sir William Thomson, Sir Samuel Canning, Mr. E. Graves, president of the Society of Telegraph-Engineers, Mr. Latimer Clark, Prof. Hughes, F.R.S., and Mr. W. H. Preece, F.R.S., past presidents of the society; Mr. Benest, Mr. R. Collert, Mr. Clifford, Mr. H. C. Forde, Mr. R. K. Gray, Mr. John Muirhead, Mr. E. Stallibrass, Mr. E. March Webb, Mr. F. C. Webb, Mr. F. H. Webb, and Mr. J. Stoddart. This brief notice may well end with the concluding paragraph of the biography previously referred to: "There are some men whose talents impress us more than any other of their merits, and stand out gaunt and bare like some projecting cliff, with nothing gentle to relieve the eye or mask the height. There are others in whom a keen intellect is sometimes veiled by geniality of manner, just as a rocky hillside may be overhung with verdure. It is to this category that Sir Charles Bright belonged, and though his past services may well command our admiration, the better part of our praise is, that those who have had the pleasure of his acquaintance, love rather to remember the

kind and sociable qualities of the man than the success of the engineer."

THE ITALIAN EXHIBITION.

Solomon, if he were alive now, would, no doubt, "Of the making of exhibitions there is no end," for seem to abound on every hand. The Italian Exhibition (Macaronaries) occupies the position this year the Yankeries held last year, but with this difference, whereas the American show depended for its attraction principally upon the "Wild West," the Italian Exhibition will really contain a finer display so far as exhibition concerned, and will depend less upon adventitious attraction.

It might almost be assumed that the advent of electric lighting made these exhibitions possible; at any rate a system of lighting is a necessity under the conditions obtain. The lighting of the Italian Exhibition is carried out entirely by Messrs. Laing, Wharton, and Co., who use the Thomson-Houston system throughout.

FIG. 3.—High Speed Compound Vertical Engine.

installation there will be 300 arc lamps of 2,000 c.p. and 100 incandescent lamps in the Welcome Club. The plan of the machine room given herewith shows an arrangement of 10 arc light dynamos of the well-known Thomson-Houston type, Fig. 1, each generating current for 35 arcs. Thus one machine will be constant reserve. The dynamos run from 820 to 850 revolutions per minute. The pulleys are 11 in. diameter, driving from 4 ft. 6 in. pulleys on the shaft. The plan, Fig. 2, almost explains itself. B is a battery of three Paxman's boilers; C E, compound girder type engine; Windsor type engines; S P, semi-portable engines of the same firm.

DAVEY PAXMAN ENGINES.

The following is the description of these engines, which will have to drive the whole of the machinery in the Exhibition, which are supplied by Messrs. Davey, Paxman and Co., who were so successful in the Fisheries, Inverness, and Colindale.

The plant, in this respect, includes two of Messrs. Paxman and Co.'s patent quick speed self contained compound engines, each of their "Windsor" type, of the following dimensions: High pressure cylinder, 11 in. diameter; low pressure cylinder, 17 in. diameter; both having 12 in. stroke. The fly wheel, 5 ft. 6 in. diameter by 11 in. thick on the face to receive driving-belt. The engine

led with Paxman's automatic expansion gear and adjustable governors. The crank pins, crosshead pins, piston rods, and slide rods are all of steel. Everything is of the very

engine, with high-pressure cylinder, 12½ in. diameter; low-pressure cylinder, 20 in. diameter by 24 in. stroke. The crank shaft is steel, with cranks at right angles and accu-

Elevation of Engines and Dynamos.

materials and workmanship. The engines are illustrated by the accompanying engraving, Fig. 3. The third engine, by Messrs. Davey, Paxman and Co., is illustrated in Fig. 4 (p. 444). One improved semi fixed compound

engine, with high-pressure cylinder, 12½ in. diameter by 17 in. stroke, and low-pressure cylinder, 20 in. diameter by 24 in. stroke. It is fitted with Paxman's patent automatic cut-off gear, worked direct from the governors, which ensure very steady and even

running by using only just sufficient steam for the work at the instant being performed. This is one of the very few automatic arrangements which work with regularity and certainty, and its high efficiency was proved by the remarkable results obtained at the trials of the Royal Agricultural Society last year. It may be mentioned that one of the large driving-bands on one of Messrs. Davey, Paxman, and Company's engines at the Health Exhibition suddenly broke when the engine was transmitting about 350 h.p.; but this automatic gear even in this extreme case—prevented the engine from overrunning.

The engine is provided with a steel locomotive boiler, for a working pressure of 120 lb. per square inch, all being mounted on a strong cast iron bed-plate, as shown in the engraving.

The same firm has also in this exhibition a high-pressure coupled compound girder engine, Fig. 5 (see p. 444). In this engine the high-pressure cylinder is 12½ in. diameter; low-pressure cylinder, 20 in. diameter × 24 in. stroke. The fly wheel is 8 ft. 6 in. diameter × 14 in. wide, turned on face to receive driving-belt. Like the other engines, this double engine is fitted with Paxman's patent automatic cut-off gear, worked direct from the governors. Our engraving shows this engine as fitted with a condenser, but this will not be used at the exhibition.

All these engines are of neat design, and all parts are easily accessible. The special requirements for electric lighting have been well considered. For instance, all the wearing parts are very large to allow the engine to be worked for long periods without stopping, and special means for lubricating are provided for this purpose.

The boilers are Messrs. Davey, Paxman and Co.'s locomotive type, each made to work at a steam pressure of 120 lb. per square inch. The shell of each boiler is made of mild steel plates, and the firebox is made of Davey, Paxman and Co.'s special improved mild steel, which is remarkably ductile, and which has given excellent results. The total heating surface of each boiler is 610 square feet.

ELECTROLYTIC BLEACHING.

The introduction of the ammonia-soda process has within the last few years considerably affected the price of production of bleaching powder, and rendered it possible to introduce, with chances of commercial success, other forms of bleaching compounds. Among the new rivals to bleaching-powder, the process of electrolytic bleaching, devised and patented by M. Hermite, has now passed from the experimental stage, and seems to be likely to be one which may be found applicable to many industries. The electrolysis of magnesium and calcium chlorides gives, as is well known, products which have bleaching properties, and in all probability hypochlorites resembling ordinary bleaching-powder are thus produced.

During the early part of last year, Messrs. Cross and Bevan carefully examined the method of bleaching based on this electrolytic decomposition, and concluded from their investigation that an electrolysed solution of magnesium chloride possessed a bleaching efficiency of considerable excess of that of a solution of calcium hypochlorite; so that the oxidising power—i.e., free in active oxygen, measured in terms of the current employed to effect the decomposition—was in excess of that calculated on Faraday's electrolytic law. They further found that such an electrolysed solution was very rapid in its bleaching action, and that there was a smaller quantity of bleaching oxygen consumed in effecting a given amount of bleaching than when bleaching powder was employed. The solution which is found to answer best in practice contained 2.5 per cent. of anhydrous magnesium chloride, and from a long series of experiments they conclude that 100 kilos of chlorine per hour can be produced by 344,000 watts, or 578 h.p., and to obtain the same amount of bleaching from bleaching-powder, 300 kilos = 6 cwt. per hour of that material must be used. Prof. Pictet has confirmed these results, and Messrs. Paterson and Cooper, the joint proprietors of the process and patents, consider that these figures are sufficient to demon-

strate the economy of the process. On the laboratory scale the mean number obtained for the yield of available chlorine is 1.25 grammes per ampere hour. Calcium chloride solutions do not give such satisfactory results, but since the greater proportion of the liquid is recoverable and capable of being re-electrolysed, the cost of the material is not such an important factor in the commercial success of the process. The bleaching liquid in the plant erected at the experimental station, and also at Belfast, where the process is being applied to the bleaching of Irish linen yarns, circulates from the bleaching tank, through the bleaching tank and back, so that by means of the current a continuous supply of the bleaching compounds is kept up, and a minimum of bleaching strength is entirely under control. In addition to the bleaching of flax yarn, the process has been used with success for the bleaching of paper pulp.

M. Hermite was awarded a gold medal by the technical jury at the Antwerp Exhibition, when the process was an untried one, and the results which have since been obtained have fully borne out the promise which these earlier experiments indicated.

The electrolytic tank, patented by the inventors, is of special construction, and is divided into two parts by a perforated partition, the circulation of the electrolysed liquid being maintained by the revolutions of a screw propeller. The electrodes are made of zinc and platinum, and are so situated to the openings in the dividing partition, that the solution must necessarily come in contact with them as it circulates. The positive platinum electrode consists of thin plates of that metal cast into a suitable support at the top, and the negative electrode is kept clean by means of a series of knives, which, by a mechanical action, keep continually exposing fresh surfaces of the plate to the liquid and prevent any deposit from accumulating. The anode may consist of any platinised material, or of glass or vulcanite, faced with specially pure plumbago, in the place of the plates of platinum we have alluded to. The circulation and uniform flow of the liquid is produced by a suitably arranged rotary pump. The rotary pump and the dynamo are both driven by belt-gearing from one motive shaft. In a later specification the inventors describe an improved apparatus, in which the zinc plates are made in the form of discs, and these are fixed to shafts, which are caused to revolve by worm gearing on a shaft which is connected with the motive shaft. Between each pair of zinc discs a platinum plate is held in a frame, and each is connected by an arm carrying a bolt to one pole of the dynamo. This modification dispenses with the movement of the scrapers used in keeping the surface of the zinc plates clean, which in this case are fixed on the partition in such a manner as to incline against the revolving zinc discs.

After the publication of the first series of experiments on this process, a somewhat severe criticism by Dr. Hurter (who cited experiments of his own on the same subject) threw doubt on the economic value of the method; and, more recently, Dr. Jurisch, in a communication to the *Chemische Industrie*, has obtained unsatisfactory results when endeavouring to use solutions of electrolysed calcium chloride for bleaching purposes. Messrs. Cross and Bevan have, however, in a recent paper delivered before the London section of the Society of Chemical Industry brought forward fresh evidence in support of their views, which leaves no doubt on the commercial success of the process. Their critics have, they contend, failed to satisfy the conditions of satisfactory working, as it is only when the electrolysed liquid is removed at once from the electrolysing cell to the bleaching vat, that the good results which they record can be obtained. In Dr. Hurter's experiments this precaution was not observed, and it is probable that the heating of the electrolyte may have caused the conversion of a considerable quantity of the hypochlorate first formed into chlorate and perchlorate, which have no bleaching value. Dr. Konrad Jurisch has based his calculation that one kilo of hypochlorate-bleaching-powder requires the energy of 18.3 kilos of coal for its preparation by an electrolytic method, as compared with only 1 kilo of coal in the Weldon process, and .5 kilo per kilo of bleach by the Hurter-Deacon method, on his laboratory experiments, in which large Bunsen cells were the source

of energy employed. No precautions, likewise, in his investigation were taken to ensure the continuous removal of the bleaching liquid as it was formed. The authors and M. Hermite are therefore satisfied with the results which they themselves have obtained, and, moreover, during the early part of this year a complete installation of their process has been erected in America, which has more than fulfilled the expectations of the preliminary trials. The formation of perchlorate in the electrolysis of magnesium chloride solutions appears to be a question of current density, since, by regulating the size of the electrodes to the current passing, it is possible to throw the electrolysis on to the water above or on to the chlorate, as desired, and precisely similar results may be obtained with potassium chlorate. We quote from their recent paper a comparative table as to the cost of the new process compared with the cost of bleaching by bleaching powder. The experiments were a continuation of those already alluded to, and were conducted at Belfast; and in the calculations for power expended, the estimate of $\frac{1}{2}$ d. per h.p. per hour is used. The mean current employed was 770 amperes at five volts.

	I.	II.	III.
Time	1h. 40m.	5 hrs.	3h. 50m.
Current	840 amp.	777 amp.	728 amp.
Indicated h.p.	7.112	6.509	6.098
	s. d.	s. d.	s. d.
Costs			
Power	0 6	1 4	0 11
Interest & depreciation	0 2	0 6	0 4
Magnesium Chloride	0 14	0 4	0 4
	0 9	2 2	1 8

That is, a total of 4s. 8d. as against 14s. 4d. for bleaching-powder.

The comparison with bleaching-powder was made on the same quality of yarn, and the bleaching was continued to the same extent in the two processes.

The best results have been obtained when the size of the electrodes is such that there is a current of about .02 amperes per square cent. We may add that Ledebor has independently arrived at similar results while investigating M. Hermite's process as those which Messrs. Cross and Bevan have brought forward.

A totally different method of electrolytic bleaching has recently been patented by MM. Brun Freres, which, it is hoped, may be found advantageous in bleaching fibrous substances used for making paper. The patentees electrify a mixture of chlorine and oxygen, the former being generated in the usual way by the action of hydrochloric acid on manganese dioxide in a retort, and the latter is stored in a receiver. After the gases have mixed, they are washed and led into an ozone generator, in which the mixture is converted into "chlor-ozone" by the passage of a silent electric discharge. The electrified gases then pass into another vessel, in which the bleaching operation is conducted. The material to be bleached is kept thoroughly agitated throughout the process, and any excess of gas not absorbed in the material is collected in a separate receiver, and used in a subsequent operation.

ON THE PRODUCTION OF INTENSE MAGNETIC FIELDS.*

BY PROF. STEFAN.

The maximum magnetic force exerted by the cylindrical iron cores of an electro-magnet between their plane polar surfaces placed opposite to each other is $4\pi\mu$, an expression in which μ represents the greatest magnetic moment that can be taken by unit volume of iron. If we assume that $\mu = 1,700$ absolute units, we have $4\pi\mu = 21,360$. The smaller the distance between the polar surfaces, the nearer is this maximum value approached.

The action exerted by cores of iron at the middle of the field may be augmented without limiting the length of the latter when another form is given to the end surfaces of the cores. This augmentation attains its highest value when they have the form of truncated cones such that the generating lines of the two conical surfaces pass through

the centre of the field, and make with its axis an angle, of which the tangent = $\sqrt{2}$, that is to say, an angle of $54^\circ 44'$.

The magnitude of the force is then determined by the formula:—

$$H = 4\pi\mu \left(0.289 + 0.886 \log. \frac{d}{a} \right),$$

in which d is the diameter of the iron cores, a the length of the field, and $\log.$ the common logarithm. This formula allows of H being raised to any required value. This fact, however, is not of great practical importance, because the value of the logarithm increases very slowly relatively to the numbers, so that conditions of construction which cannot be realised are soon arrived at.

If $H = 8\pi\mu$, we must take $d = 85a$.

In some optical experiments, it is necessary to perforate the iron cores. In this case, it is no longer correct to say that the nearer the polar surfaces the more intense is the magnetic field. The magnetic force at the centre of the field attains its highest value when the distance a of the polar surfaces satisfies the equation—

$$a^2 = d^2 \frac{n+1}{n-1},$$

in which d represents the diameter of the opening, and n , the number indicating the ratio of the diameter of the iron cores to that of the opening.

The perforation of iron cores is always attended with great deformation of the magnetic field. The intensity diminishes sensibly from the centre to the extremity of the field. At this latter point the force between the plane polar surfaces is less than half that in the middle of the field. The iron cores with conical extremities above described offer also the advantage of giving, when they are perforated, a greater intensity in the middle, and a smaller diminution of force near the extremities of the field.

PORTABLE ASTATIC GALVANOMETER.

The portable form of astatic galvanometer, illustrated herewith, and constructed by Messrs. Woodhouse and Rawson, is made either with a pivoted or suspended needle, and is very sensitive. It has two pairs of coils, one of high and the other of low resistance, either of which may be

fixed and put in contact by simply removing the glass cover and dial and pushing the coils into place, when they make contact automatically. The case is of brass, mounted on ebonite, with three levelling screws. A megohm resistance is included in the base of the instrument. When desired, a separate terminal is provided for that purpose, so that the instrument can be used for insulation tests. The outside dimensions are only 3in. by 2½in. deep.

The Commercial Phonograph.—The contract for making the woodwork of the Edison phonograph and the Edison mimeograph was closed a few days since with the Gilliland Electric Company, Adrian, Mich. It is a very large one, and necessitated for its rapid execution the very latest improved machinery, which was found in the shops of the Egan Company of Cincinnati, whose woodworking tools have a wide recognition. The long-looked-for and much-talked-of "Talking Machine" will soon be placed before the public.

* Read before the Vienna Academy of Sciences, February 9, 1888.

FIG. 4.—Semi-Fixed Compound Engine.

FIG. 5.—Compound Horizontal Girder Engine.

losers, will rather be gainers. There is no reason at all, except woeful mismanagement, why the principal cable companies should not pay a ten per cent. dividend with a much lower tariff. Our remarks hitherto have been general, but it may be as well to make one special reference. The chairman of one of the trust companies the other day condoled with the shareholders as to the state of their finances, pointing out that this state was wholly due to the position of some of the Atlantic companies. Now that chairman was one of the directors who put the Atlantic companies in the position they occupy, and none know better than he that the position need never have arisen and need not continue. Arbitrary and self-seeking to a degree far beyond the merits of the case, these directors have so acted that the shareholders have lost hundreds of thousands of pounds, which can never be regained. Weeks, months, nay, possibly years ago, their competitors were willing to agree to a moderate and remunerative tariff, though they consistently and persistently refused to put their necks under a yoke held by avowedly hostile hands. The Commercial Cable Company says that a shilling tariff is fair and that it pays, and we believe this statement to be unanswerable, those who contend it is not, dealing in what may be euphemistically termed uncertainty in veracity. The men who have caused the loss of these thousands are kept in their office simply and solely because of the control they exercise over the trust companies. And we warn America that if such companies are permitted to take root, they will be detrimental to the industry. Control means playing into the hands of those who control. Those who hold the reins do not pretend to drive through purely philanthropic motives. With them "the jingling guinea helps the hurt that honour feels"; in other words, nothing is done unless it is, directly or indirectly, going to put money into the pockets of those who control the machine. Let us see how the thing works. Suppose the Trust Company started. A, B, and C subscribe largely to the funds of the company, and are elected, or elect themselves, directors. They hold the proxies of the trust. A is made a director of an electric lighting company, and takes just enough shares to legalise his position. He is also a director in a carbon manufacturing company, in an ironworks, in a paint mill, and a dozen other concerns, because being all-powerful in a lighting company, he influences those from whom carbon, paint, iron, &c., shall be bought, and so the game continues. The shareholders at every transaction put a little money into the pockets of A in some way or other, and thus he grows rich. Verily, my masters, this game is well worth the candle. It is what will go on in America. It is what does go on in England. A deeper game is to so manipulate affairs that a five or six per cent. dividend is paid by a concern that would as easily pay ten, so that too close a scrutiny is not made into

ways and means of management. A man who gets five per cent. is fairly satisfied, and does not enquire too closely whether the five ought not to have been six. Trust companies are a power in the hands of those who know how to work them with skill. It is a pity some of the masters in the art who flourish among us do not emigrate to the newer hunting ground in America. Their country would not regret their absence nor yearn for their return.

PARIS.

The municipal authorities of Paris have promulgated a series of rules to be followed in laying electric light mains and networks of service wires. The authorities are farsighted enough to see the possibility of their undertaking the supply of electric current for lighting and power purposes. It may be in addition to or in competition with the companies presently to be formed for similar purposes. Hence various important reservations are made, whereby the authorities, if they ever do proceed with the work, will obtain exceptional advantages over the companies. However, we do not find fault with those who have an eye constantly directed to the main chance—our intention being not to criticise so much as to direct attention to these rules. Our municipal authorities, or rather the engineers and surveyors to borough and other authorities, will be requested to advise as to the rules to be followed in the various localities where electric light installations for general lighting are projected. The Paris authorities deserve all our thanks for having taken the initiative in this matter, and although the rules proposed may be very imperfect, it is far easier to amend than to construct. Doubtless these rules will be attentively considered, and such alterations made as will render them suitable for places other than Paris. It will be seen that the draughtsmen of these rules assumed that the work would be underground. There is an Association of Municipal and Borough Engineers, which meets periodically and discusses questions relating to their work. Might we suggest these "rules," or a paper upon this question, as a most suitable subject for discussion. The electric light engineers would be only too pleased to contribute of their experience towards the enlightenment of the men with whom they hope to be brought into closer contact. In all that concerns electric lighting Paris has stood in the front rank. Early in the forties, experiments were carried on in the Place de la Concorde by M. Archereau with an arc light, but, of course, the cost of the current obtained by means of a voltaic combination of two hundred pairs made such lighting economically out of the question. It was Paris that gave the electric lighting of the past ten years the filip that made it popular and possible. It seems that Paris is to pave the way in defining the connection between con-

tractors and municipalities when electric lighting becomes general.

CORRESPONDENCE.

REMINISCENCES OF THE LATE SIR CHARLES BRIGHT.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—The very lamentable and sudden death of our much esteemed and congenial member of the electrical world, Sir Charles Bright, may have so taken your biographical writers by surprise that perhaps a few words embodying some of my reminiscences of Sir Charles may prove of interest to your readers. I was twice his principal assistant—once in 1863, until the Persian Gulf cable was laid in 1864, and again for a few months at a later period.

I can recollect many little traits of character that struck me suddenly at the time, and that showed me he had a kindly heart. I recollect once when I, in my zeal for pushing on the work of fitting out the five ships for the Persian Gulf cable, pressed Sir Charles to take some violent steps against the late Mr. W. T. Henley. "No," said Sir Charles, "I won't do that. Because we have the power of giants, that is no reason why we should use it!" I was silent for some time. I accepted the rebuke, and I hope I have ever since recollected and acted on the moral of the words, which showed a kindly and considerate heart.

Then, again, I recollect how Sir Charles used to whisper to me when we were paying out cable from the "Marion Moore" at night. "Come down below," he said, "my servant is opening a tin of Bath chaps"; and down we went, and I never enjoyed anything in the Persian Gulf so much as these little impromptu suppers which Sir Charles suddenly invited me to. Once, I recollect, when we arrived on board the P. and O. steamer, off Suez, we were absolutely starving, but so *Medes and Persians-like* were the laws of the P. and O. Company then, that, as dinner was over, we could not get a scrap to eat. Sir Charles was always a model of discipline, and would not even raise his voice on the subject, but determined to suffer hunger in silence so as to show an example to his impatient and excitable assistant. We paced the deck in silent hunger for some time, then Sir Charles began to suggest that we should discuss quietly what we should like to have for dinner. I immediately fell into the idea (I always was imaginative, if nothing else). "Julien soup," I exclaimed. "No," said Sir Charles in a grave tone, "half a dozen oysters and a glass of Chablis." "Good," I said, "I see you understand the matter better than I do, Sir Charles. But still," I said in a pensive way, "Julien soup would not be bad on empty stomachs like ours; however, I waive the point and accept the oysters, such as they are." "Let us get on to the fish," said Sir Charles, as we paced the deck faster and faster in the deepening twilight. "*Filet de soles au gratin* is a favourite dish of mine, Sir Charles; would you mind me having that?" "Certainly, my dear fellow, by all means; but I must have some cod and oyster sauce to follow." "*Tête de veau en tortue* is not bad when you are nearly starving, and the stomach is in a weak state." "That is true," said Sir Charles, "but '*petits pâtés à la Victoria*' are not bad," and so we went on pacing the deck until we were obliged to turn in awfully hungry. I dreamt about that dinner, of course, all night, and then I awoke to a ship's boy bringing me a cup of P. and O. ship's coffee, and I suppose that every telegraph-engineer or electrician knows, to his own cost, what P. and O. morning coffee is. If they don't know, I advise them not to try to know, don't you know.

I believe the P. and O. have reformed since then, so enough of that story, but I shall never forget it.

Let me try to think again.

Once, when we were turning some cable over into a gunboat, about two miles off Boshire, a mistake, between myself and a young clerk, had been made as to the number of revolutions of the machine that was measuring the cable that was being transhipped to the gunboat. The mistake was discovered, and I was in consternation. We were shipping into the gunboat enough to land five shore ends. Sir Charles grasped the situation in a second, and instead of

blowing me up (which "blowing up" I should probably have passed on to the real culprit, a poor harmless clerk), simply said in the coolest manner, "I will go ashore, Webb, and carry all the critics with me."

I could find in my memory, if I had time, many another small anecdote which would show the kindly feeling that existed in the heart of Sir Charles Bright. —Yours, &c.

F. C. WEBB.

THE EQUITABLE TELEPHONE ASSOCIATION.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—It having come to the knowledge of the Equitable Telephone Association that the agents of the United Telephone Company are circulating reports to the effect that the Association have not the intention or the means of defending the action for infringement of patent that the United Telephone Company have thought fit to commence against them, the Association ask the favour of your space to give these most unwarranted reports an unqualified contradiction. They also take the opportunity of stating that not only have they the fullest intention of contesting the action to the utmost, but have also every confidence that they will be successful in upholding the freedom of their telephones.—Yours, &c.,

A. A. C. SWINTON, Director.

The Equitable Telephone Association, Limited, London, E.C., May 4th, 1888.

PRACTICAL USES OF THE ELECTRO-MAGNET.

The following description of the practical employment of the electro-magnet is taken from the *Pittsburg Press*:—"S. T. Wellman, the superintendent of the big steel works at Cleveland, conceived the notion some time ago that a large electro-magnet, suspended by a chain from a crane, could be employed very profitably for lifting masses of iron. Not being an electrician, he did not see his way to carrying the thing out practically. Mr. Berry, an electrical engineer of Pittsburg, being on the spot, volunteered his advice and superintendence. Together they brought the thing to completion, and it is now working with great perfection. For the construction of the electro-magnet to be experimented with, two bars of soft iron were taken, each being 15 in. long and 3 in. in diameter. They were wrapped with a multitude of strands of No. 14 B. and S. gauge covered wire. To combine the two separate magnets thus formed into one, they were linked together on top by a third soft iron bar, square in the cross section. For trial of the magnet at portable work, it was suspended by a rope from a pneumatic crane. Rope was used, as it was found that a chain became magnetised and did not act very well. The current power sent through the wire to induce the magnetism was that of 5½ to 6 amperes. It was found that a weight of 800 lb. could be lifted up handily, and, by shutting off the current and lowering the magnet, deposited anywhere very easily. . . . At one part of the factory where this electro-magnet has been put up, fourteen or fifteen Polacks have been wont to be kept employed at this work. They are now in the position of Othello in the matter of occupation, the magnet picking up two or three billets at a time and depositing them in a car. If the thing works permanently, as it appeared to be working when Mr. Berry left Cleveland, it looks as if one boy would be able to do the work of a gang of men. His duties will be those of lowering the magnet from the crane on to some billets, turning on the current, swinging the magnet around to the top of a car, cutting off the current, and bringing the crane back to its first position. The crane used is one of a very superior class, being adapted to turning in any possible direction almost at a slight movement from a pneumatic valve. The turning off and on the electric switch, of course, would require no expenditure of energy that would be worth speaking of at all. It is intended to construct an electro-magnet of softer and more appropriate iron than that of which the first experimental one was made. The amount of current, also, will be arranged so that only a portable capacity of 150 lb. or so at the poles of the combined magnet will be produced."—*Scientific American*.

THE STOCKER BOX TELEPHONE.

We illustrate this week the Stocker Box Telephone, a form much in use in Germany, manufactured by the firm of Stocker and Co., Leipzig. The transmitter consists of a desk-shaped case, the lid of which is formed by the iron

vulcanite mouthpiece screws upon this, keeping the iron membrane tightly stretched. In the centre of the box stands the coil with its iron core. So far the Stocker Box Telephone does not differ from other known forms, but it has its own special arrangement of magnets and pole-pieces. These are made of square steel, bent in an arc of

FIG. 1.

vibrating membrane. The case itself contains the microphone and the self-acting switch, and, in type 2, also the works of an electric bell. The microphone is the usual form, with two sets of five carbon rods and three connecting pieces. Fig. 1 shows this transmitter with the ordinary

FIG. 2.

Bell receiver. The alarm in this case is fixed in a suitable place, and connected by a wire to the binding screws shown.

Their own type of box telephone has several new features. It consists, as shown in Figs. 3 and 4, of a small round flat brass box; the upper edge is threaded, and the

FIG. 3.

nearly 300deg. One pole of this circular magnet carries a connecting piece of iron in connection with the under end of the bobbin core. To the other pole a similar connecting piece is screwed, which carries a ring of soft iron bent round the outside of the coil (Fig. 3). One end of the magnet

FIG. 4.

FIG. 5.

therefore forms the central core, and the concentric ring-shaped pole, which goes round the bobbin, forms the other end. The centre of the iron membrane is by this means actuated by both poles of the magnet, obtaining thus both the strongest and the most equally distributed magnetic

effect, a condition which gives the best speaking qualities. The combination of central core poles, with ring-poles surrounding the hobbins, has, indeed, been attempted in other

netic effect with the smallest space, in connection with which point it should be observed that Figs. 3 and 4 are full size, the weight of the telephone being less than $\frac{1}{2}$ lb.

FIG. 6.

FIG. 7.

FIG. 9.

FIG. 10.

FIG. 8.

FIG. 11.

ways, but not in connection with circular magnets, as in the Stöcker telephones. This construction is admirably suitable to its purpose and very effective, giving the strongest mag-

For writing desks, a movable form of telephone is supplied, shown in Figs. 6 and 7, consisting of a square box mounted on a pillar, containing microphone, induction coils,

switch, and electric bell. The microphone used here is the ordinary vertical arrangement.

These telephones have been greatly used in private installations, but are coming, by degrees, more and more into use for central exchanges. Of the apparatus for exchange use, we illustrate the fall plate indicators and the contacts. Fig. 8 shows the indicator. The fall-plate is kept in position by a catch at the end of an iron arm, which forms the armature to the magnet. The further short end of this bar is pulled downwards by a short spiral spring, the tension of which can be regulated by the screw. When the armature is attracted it frees the fall-plate, which is pushed outwards by a small flat brass spring, and falls forward.

The connection between two wires is worked by push contacts, in the manner shown in Fig. 9. The wire from the fall plate is led to the contact spring; this, as long as the push is not inserted, rests upon the underneath contact point, which is connected with earth. When the push is inserted, it raises this spring and disconnects it from earth, at the same time making communication with the required wire.

Fig. 10 shows the alternate current bell of the same firm. Two permanent horse-shoe magnets, placed side by side, are furnished with small electro-magnets on their upper poles, which are disposed in such a manner that, by the flow of the current in one direction, one of the poles is strengthened, and the other opposed; by the opposite direction of the

FIG. 12.

current, the first is opposed and the latter strengthened. Between the four poles, mounted on a axis, is a soft iron bar, on which the bell hammer is fixed. The action of these four poles is as follows. 1, 2, 3, and 4 being the four

poles, and *a* *b* the mounted armature, 1 and 3 will pull the armature in one direction, and 2 and 4 in the opposite. If now 1 is strengthened, and 2 weakened, the effect of 1 and 3 will overcome that of 2 and 4, and the armature will go to 1 and 3. The opposite will occur when 2 and 4 are stronger, and the armature with each change of current will move backward and forward.

Figs. 11 and 12 illustrate an electric bell indicator which differs somewhat from the ordinary construction. A single spool electro-magnet is fastened upon an iron base plate, which is screwed to the back of the indicator case. Under the magnet, springing out of the base plate, are two projections; on these are two pointed screws, which act as axis to the armature. This is bent at right angles, and carries on its upper end a catch, which holds the arm of the fall piece. This arm, to which the number is fastened, is mounted on an axle, turning horizontally on a pin in the base-plate. On the other end of this is the second arm, by which the indicator is raised in the ordinary way. When the armature is attracted, the catch releases the arm, which therefore falls.

The motion of the armature is controlled by the screw seen below.

ELECTRIC LIGHTING.

Proposed conditions of contract under which electric light wires may be laid in the streets of Paris:—

(Continued from page 416.)

CHAP. II.

NATURE, DURATION, AND CONDITIONS OF AUTHORISATION.—
WITHDRAWAL OF AUTHORISATION.—REDEMPTION.

Duration of the Authorisation granted without Monopoly.

ART. 11. The present authorisation is granted for a period of 18 years from the date of the notice of approval, without any monopoly or privilege. The town of Paris reserves to itself the absolute right of granting other authorisations of the same kind, even within the extent of the system of ways to which the present authorisation applies.

Nature and Limitation of the Guarantee granted relative to Sites.

ART. 12. The town of Paris undertakes to reserve to the licensee, to the exclusion of all others, during the period of the authorisation, the sites reserved for his system of conductors.

It reserves to itself the right to order, and even, in case of urgency, to effect the removal or withdrawal, at the cost of the licensee, of any portion of his system of conductors whenever the interest of the public or of the municipal service renders this course expedient. The licensee will be requested at least five days beforehand, except where this may be impossible, to carry out these removals or withdrawals, and, in case he should fail in this, the town of Paris can take the necessary steps to do so at the expense of the licensee and without his being entitled to any indemnity.

Tariffs.

ART. 13. The licensee must have a uniform tariff for all subscribers to his system, provided always that this shall not exceed 0.06f. for one candle hour, or 0.60f. for a quantity of electrical energy supplied to subscribers equal to one horse-power per hour. The drafts of his subscription policies, in which the luminous intensities are to be referred to the candle,* taken as unity, should be approved by the Administration after the approbation of the Municipal Council.

The town of Paris reserves the right of lowering the above given minima of prices every five years from the date of the notice that authorisation has been granted.

This revision of prices, which will be based upon the progress made in any direction by electrical industry, whether from the point of view of manufacture or of cost, will be brought forward six months before the expiration of each period of five years by the Municipal Council on the report of a consulting committee formed of four members, two of whom will be appointed by the council in conjunction with the Administration, and two by the licensee.

In case the licensee should not nominate experts, the nomination will be made by legal authority at the request of the town of Paris.

The decision of the Municipal Council will take effect from the commencement of the new period.

The policies, supplements, articles, or agreements taking effect between the licensee and his subscribers are to be in threefold copy, one copy of which, signed by the society and the subscribers, shall be forwarded to the town of Paris.

Any reduction in the tariff granted by the licensee to his subscribers will be considered as permanent until the expiration of the authorisation, and the tariffs may not again be raised.

Obligation to Accept any Demand for Subscription within the District worked.

ART. 14. The licensee shall be obliged to supply, under

* The candle is to be determined as in the deed between the town of Paris and the Gas Company.

the conditions of his policies, electricity to any person demanding it within the extent of the system worked, except within the three last years of the authorisation granted.

He absolutely disclaims the right to insist upon the carrying out of the interior installations of subscribers.

Supervision.

ART. 15. The licensee shall be found at all times to arrange, at his expense, the installations necessary for all photometric trials and all verifications which the Municipal Council or the Administration may think fit to carry out.

Dues.

ART. 16. The licensee shall pay quarterly to the town, during the whole duration of the authorisation—

1. A sum of 100 francs per year for each kilometre or fraction of a kilometre of conduits laid down;
2. A rate of—

5%	during the 3 first years of the authorisation
6%	" 3 following years
7%	" " "
8%	" " "
9%	" " "
10%	" last 3 years.

on the verified receipts—verified either by the amount of the subscription policies, by the indications of counters, or by other means which the Municipal Council may elect. The above applies both to lighting and to motive power. With a view to the above, the licensee shall every quarter draw up accounts of receipts and expenditure in the course of the month following the expiration of the quarterly period. No deduction shall be made by reason of non-payments; but every cessation of subscription duly indicated by the licensee will be taken into account.

The licensee will assign to the town of Paris 15 per cent. of the profits which he may realize upon electrical installations made by him in the town of Paris without the use of the public roads.

Supplementary Dues in Compensation for Town Dues when Electricity is generated outside of Paris.

ART. 17. In cases where electricity is generated in works outside of Paris, the previous deduction on the gross receipts is to be increased by one per cent.

If the town dues in relation to coal should undergo any variation, the supplementary dues are to vary in the same proportion.

Period allowed for Payment and Obligation of the Licensee to Produce all Documentary Evidence.

ART. 18. The licensee shall pay every quarter the above-mentioned dues, within a period of eight days from the date of application for payment made by the municipal receiver. He will supply every necessary information to the functionaries or agents of the town whose duty it is to verify the accounts in relation to these dues. More especially is he to place at their disposal the books and documents which they may require.

Supervision to be at the Cost of the Licensee.

ART. 19. The expenses of the supervision exercised by the town are to be paid by the licensee, and they may be applied for within the first fortnight in January, and shall be considered due to the town from that period.

Conditions of the Withdrawal Authorisation.

ART. 20. The authorisation shall be withdrawn after notice from the Municipal Council—

1. If the licensee should transfer to third parties the whole or a portion of the rights and obligations ascribed to him in the present condition of contract, without the express authority in writing of the Prefect of the Seine after notice given to the Municipal Council.
2. If he has not commenced the working within the period of six months from the date of the authorisation, and if within a period of two years he is not in a position to satisfy any demand for electricity within his system of conductors.
3. If during the period of the authorisation he suspends the distribution of electricity, over the whole or a

portion of his network, without authority from the Municipal Council.

4. If the licensee should not conform to the obligations imposed upon him in the present conditions of contract.

Any portions of the conductive system authorised to be carried out, and that shall not have been utilised within a period of two years, or which have ceased to be utilised, shall be withdrawn from the licensee.

In case of bankruptcy or failure of the licensee the present authorisation shall become null and void.

Conditions of Redemption.

ART. 21. The town of Paris reserves to itself the right of redemption at any period, after the expiration of the 10 first years of the duration. The terms of redemption shall be determined in the following manner:—

1. The mean annual nett returns obtained by the licensee during the five years preceding that in which the redemption is to be carried out shall be calculated.

These mean nett returns shall constitute the amount of an annuity, which shall be due and paid to the licensee during each of the remaining years of the duration of the present authorisation.

It shall be open to the town to redeem the remaining annuities by the payment of a capital sum representing the actual value of these annuities at a rate of interest of five per cent.

2. In regard to the system of conductors, the machines and apparatus of every description, the tools in the work-shops, the furniture of the offices, the lands, buildings, &c., and generally to all things employed by the licensee in his working, the town of Paris will take them over in entirety according to their value at the period of purchase as determined by experts.

This value shall be paid to the licensee within six months following the period of purchase. In consideration of the payment of this purchase price, the licensee shall assign to the town all his rights and privileges, leases, locations, contracts for sale, &c., provided always that this assignment shall in no case have the effect of implicating the town in any actions at law or legal difficulties which may exist between the licensee and any of the third parties at the period of sale. In view of the obligations of this clause, the licensee is forbidden to alienate, or to mortgage to any person whatever, the premises constituting the property of the company or any of the installations, either beneath the public roads or any private property. The premises belonging to the licensee, but which are not yet utilised in the working to which the present authorisation applies, are excepted from this clause.

Surrender of Localities in Proper Condition at the end of the Period of Authorisation.

ART. 22. At the period assigned for the expiration of the present authorisation, the system of conductors will be the property of the town unless the latter should prefer that it should be removed, and in this case the localities shall be restored to their original condition at the expense of the licensee, under his directions or otherwise, without his having claim to any indemnity.

The above applies also in case of the withdrawal of the authorisation either for the whole or for a portion of the system of conductors.

(To be continued.)

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

CENTRAL STATION LIGHTING—TRANSFORMERS v. ACCUMULATORS.—DISCUSSION.

(Continued from page 430.)

Mr. Gordon considered that enough had been said to almost persuade Mr. Crompton, but, probably, that gentlemen would have taken a different view had he been present. The lead diagrams which Mr. Crompton had produced showed clearly that in America, as in England, the period of heaviest load was about the dinner hour. The stars in their courses seemed to fight against the transformer system, which, besides possessing inherent defects required for its success that overhead wires should be allowed to be run, that an E.M.F. of 2,000 volts

should be permitted, and that all spare gear should be omitted, so as to cut down the capital outlay to make a good comparison with the accumulator system. His experience of the absence of spare gear showed that it had a depressing effect upon the engineer's attendants. Mr. Crompton was at a disadvantage, as he could not quote actual facts without appearing to advertise his own system, which was contrary to the spirit in which papers, and the discussions upon them, should be brought before the society. He himself had no interest in any particular apparatus, and could speak with less reserve. He had entered into a contract with Mr. Crompton, dated 22nd December, 1887, which provided that eight batteries of 60 cells, and 12 spare cells, making 492 in all, should be supplied for £3 320, or 26. 16s. per cell, but, as four of such cells would equal one of the cells taken in Mr. Crompton's estimate, £27 should be taken to be compared against his quotation of £40 per cell. The normal discharge of the quarter-cell was to be 105 amperes with a capacity of 525 amperes, the cells were to be capable of discharging at 200 amperes with a capacity of 375 amperes, the efficiency at 105 amperes to be not less than 75 per cent., at 75 amperes not less than 85 per cent., and at 45 amperes not less than 90 per cent. Any inefficiency was to be met by the contractors at their own expense. The contract was for five years, the cells to be kept in all respects equal to new for 12½ per cent upon the contract price. Those were actual facts which Mr. Crompton could not state for himself.

Mr. Sellen congratulated Mr. Gordon for having entered the breach as an advocate of secondary batteries. He had never heard such a one-sided discussion before at a meeting of the society. Prof. Forbes had criticised the figures given by Mr. Crompton so unfavourably as to make transformers appear, relatively, far more economical than accumulators. Overhead wires would not be tolerated in this country, and having been in the United States not many months ago, he knew that the alternating current systems there were carried out only because the Americans accommodated themselves to circumstances which were simply not admissible in England. No sane engineer would attempt to lay down overhead mains to supply an installation of 100,000 lights, and there was no experience to show what would be the condition of such a system when riddled right and left underground. Mr. Hammond's experience with alternating currents on an underground system, supplying a few hundred lights with mains a few miles long, did not enable a conclusion to be drawn as to what would occur when 100,000 lights were fed. The fact that even the most ardent advocates of alternating currents, of whom Mr. Kapp was, he thought, an instance, were prepared to adopt batteries when they were sufficiently reliable, was an absolute acknowledgment that a system based upon the employment of batteries was the ideal system, and an admission that the alternating transformer was only a stop-gap system. Secondary batteries had been subjected to much odium, and had got into disrepute on account of insufficient attention because they did not change colour, or do anything remarkable before going wrong, and, therefore, the workmen treated them as being all right. In the hands of competent men the difficulties disappeared. He would ask Mr. Crompton what he would do in the case of an installation of 100,000 lights, as against that of 10,000 lights which he had calculated for. Would he increase the number of local centres placed in series from a single source of supply, or have a separate generating station for every set of four sub-centres? In the former case the difference of potential would rise to something considerable, and the danger of leakage would be so great that the charging and discharging must be done at the same time; or there must be two sets of batteries as in the B.T.E. system, which did not allow of charging and discharging at the same time. If, however, a system of continuous current transformers and batteries were used, then during the period of medium demand, about one-half of the time, the whole plant would be in operation, but there would be a surplus current which would go to charge the batteries and during the period of minimum demand the batteries would supply the necessary current. Such a system had the advantages of being able to charge storage batteries and supply motive power, and avoided the necessity of having a bulk of batteries to supply the whole of the current. Some people might regard one as a harmless imbecile for suggesting such a system, because the continuous current transformer was a revolving piece of mechanism, difficult of insulation, and all the rest of it. That was true, but such transformers would not be placed on consumers' premises, and in local centres, which were a necessity, whatever the system of distribution, it did not matter whether the mechanism was revolving or stationary. A little more attention was required by revolving apparatus, but there were compensating advantages. He was quite convinced that a battery system would be the system of the future.

Mr. Robert Hammond pointed out that the systems at Brighton and Eastbourne were not the small matter of a few hundred lights and a few miles of wire, but should more properly be referred to as consisting of a few thousand lights and 22 miles of wire, which had been in work for seven years.

Mr. Bernard Drake: I quite agree with Mr. Crompton that those of us who are connected with the manufacture of secondary batteries are much indebted to him for the way in which he has pleaded our case, but I do not think we have much to thank him for in having alluded to Mr. Hammond's work as "temporary lighting." This has brought upon the offending battery a perfect storm of abuse, which I cannot help thinking it would have escaped if Mr. Hammond had been left alone, especially as this gentleman has only lately put down some of this maligned apparatus for the lighting of his own house. The first question which we have to consider, in comparing the systems, is, supposing that both are working over the same area, which is to be preferred by the public? My own opinion is that the battery system would carry the day, even though 1s. per unit were charged, instead of 7d. In the first place, they are afraid of the high-tension system, and also are prejudiced in favour of the idea of pumping into a reservoir from which you draw as required, and it appears to them, from a common sense point of view, that this is more reliable than

depending on moving machinery. Battery systems must be divided into two distinct classes, those in which the battery is charged in the day time and afterwards separated from the dynamo and discharged on to the lamps, in this case the depreciation will amount to 15 per cent, and the efficiency to 70. The second system is where dynamo and cells are run together during the heaviest part of the lighting, when the depreciation will be about 7 per cent, and the efficiency 85 or 90 per cent. There seems to be a prevailing notion that the very presence of batteries in the installation involves the loss of 40 per cent of all the current used in the lamps. This is not the case. It is only the current which goes into the batteries and is reconverted back again that suffers any loss. If a charging current of 500 volts is employed, there will be no danger to life; no loss in conversion of the current used by the lamps to the full extent of the dynamo output, there can be no sudden breakdown, the station can be worked with one shift of men, and the engine constantly kept going at the point of greatest economy. Under these circumstances, I cannot but think that batteries will compare very favourably with secondary generators. The main question is the depreciation of the batteries, and I quite agree with Mr. Sellen that the past is no criterion, for they have been placed in isolated installations in the hands of people who have no idea how to use them. Batteries properly looked after will last twice or three times as long as those which are not under proper supervision. I was glad to hear from Mr. Crompton that the cells which Mr. Gorham and I made for the Vienna work, for which he made the dynamo, are doing so well, as also those which we made for Mr. Freese. There is another case to which I would refer, probably the oldest battery in London, namely, those at the P and O offices, the plates for which were made even before we became connected with the Storage Company. These cells have lasted four years, and are now in perfect order, a result entirely due to the way in which Mr. Hall, the engineer, has looked after them. That batteries can be seen which have worked in this way clearly shows that they can be relied upon under certain conditions, but for the present I do not agree with Mr. Crompton that in first cost and maintenance they can be made to compare with the secondary generator system. Where expense is the main object, the district is spread, and large halls have to be lit more than private houses, the alternating system will undoubtedly be most used, but I do not attach much importance to the fact that in America the transformer system is the only one which has made any way, for the Americans have practically only one company who are devoting themselves to making secondary batteries, and they came over to England only a year or so back to learn how to make them. If the same amount of brain and time had been expended on batteries in America as on transformers, we should no doubt have heard from Prof. Forbes of the hundreds of tons of batteries he saw, as well as the large quantities of transformers. Automatic contrivances will, no doubt, be useful; but I see no reason why the system should not be started without them, provided the cells are put in central distributing depots, for the man in charge can easily switch the batteries in and out by hand, as required. In America one sees five or six large engines and dynamos side by side, but it has never been stated that the station could not succeed because the engines do not start and stop automatically according to the work in the lamp-current. Finally, I am of opinion that both systems can be made to work quite satisfactorily, and to pay their way, but I am convinced that the question as to which system is most largely adapted for the next few years in England will depend very much more upon the engineers than upon the system itself. Whichever gets the best men in the early days will become fashionable, and more time will be devoted to its development. If the battery system only receive the same attention as the secondary generator system, and good practical engineers are interested in its development, I cannot but think that the battery system will hold its own both now and in the future.

Mr. Frank King, as the first man in England who put a system of secondary battery distribution into practice, at Colchester, had read Mr. Crompton's paper and listened to the arguments with much interest. Mr. Crompton might have utilised a higher tension for his charging arrangements. He had himself used at Colchester an E.M.F. of 1,250 volts for two and a half years without hitch or difficulty, and the cables when taken up were as perfect as when laid down. At the residence of Baron Rothschild, 535 volts were supplied through a mile of charging cable, underground, without trouble as regards insulation. Mr. Crompton's provision of only four subsidiary stations was too little. At least 10 battery stations were required, though for an area like Kensington probably six would do, but certainly not four. He was a strong advocate of the storage system, and his experience was that reliance could not be placed on the continuous running of any dynamo machine. The system must be such that the consumer should always have his maximum light available, and there should be no risk that the dynamo might fail at the moment of maximum load. A statement in regard to the durability of storage batteries were based upon batteries which possessed inherent defects, but there was not the smallest reason why a battery should not be made in which it would be absolutely impossible for any wasteful internal action to take place. The deposit of life out of 16lb. active material mentioned by Prof. Forbes was beside the matter altogether. They did not put just enough active material into the cells to give the durability wanted, sometimes it was four or five times as much. Engineers who proposed using storage batteries would come to grief if they attempted to charge a number of them in parallel. Storage cells must be charged in series so that they should all receive an identical charge. He agreed with Mr. Crompton's proposal to be bricked from here, for he had used them at Colchester, and they remained as good as when first laid.

Mr. Stuart Russell pointed to successful instances of underground cables having been laid. Early failures were due to insufficient insulation, and the cables were often defective before a current had been sent through them. Underground cables were used for the A.T. system in Philadelphia, which had not been referred to by Prof. Forbes, and it was stated in a recent discussion at Pittsburg that some fifteen miles of

underground conductors were working with very satisfactory results with the alternating current system. At Milan, cables were used for 1,500 volts continuous, and 2,000 volts alternating current circuits. In the tunnels in Brussels some few miles of cables worked satisfactorily with 1,400 volts continuous current. The Colchester and Eastbourne cables had been already referred to. At Silvertown, their experience of underground circuits extended for five years, the positive and negative conductors for arc light circuits lay together in the same trench and no repair had been necessary at all to the cables. If a high-tension system of any sort were used, no doubt present knowledge would enable it to be put underground in such a manner as to give satisfactory results. He considered that Mr. Crompton had been too liberal in his allowance for support for his mains.

Mr. C. T. Fleetwood said that brick subways 18 inches square were not possible in London streets. It was frequently difficult, from the presence of supply pipes of various kinds, and owing to coal ducts and cellars, to put down 3in. pipes. His experience convinced him that iron pipes containing well-insulated conductors was the best system practicable for the vast City of London.

The discussion was then closed, and the President announced that Mr. Crompton would reply on May 17th.

Correction. In the report of the speech of Mr. W. B. Eason in last week's issue, he asks us to correct as follows. For "distribute from four centres at an aggregate of 600 volts," read "distribute from four centres an aggregate current of 6,000 amperes," and for "two systems of distribution before them, one by means at low potential, 100 volts, and the other at high potential, 2,000 volts," read "two systems of A.T. distribution before them, one from a few transformers by distributing mains at 100 volts, the other by transformers in each house with a high potential charging network at 2,000 volts."

PARLIAMENTARY INTELLIGENCE.

COAST TELEGRAPHS.

In the House of Lords, on Friday, April 27th,

The **Earl of Morley** rose to call attention to the report of the committee appointed by the Board of Trade to inquire into the desirability of electrical communication between light vessels and sailing lightships and the shore. He said that an interesting discussion on this important question had been recently held at a meeting of the Associated Chambers of Commerce, and at a meeting of the Plymouth Chamber, of which he was a member, a debate had been held on the question, which was well worth attention. The committee has dealt exclusively with lightships and lighthouses on the Thames, though the recommendations of some Chambers of Commerce went so far as to urge that cables all round the coast should connect all the lighthouses with the General Post Office system. That, however, would probably involve too great expense. He hoped that the Bill which he believed was shortly to be introduced would enable Lloyd's to purchase sites for their signal stations. Where there were communications by rockets or guns, the rockets might not be seen and the guns might not be heard, particularly in the case of fogs. He need not dwell on the enormous importance of time in these cases. A few hours, often a few minutes, made all the difference between absolute disaster and the saving of life. He quoted from the experience of the coxswain of the life-boat at Ramsgate to show the inestimable value of telegraphic communication, and that under the present system of rockets a wreck might lie for many hours in great peril, without those on land, 20 miles away, knowing anything about it. He particularly mentioned the case of the "Indian Chief," which got aground early in the morning. In this instance, telegraphic communication would have been of the greatest importance. He thought it would be sufficient to read one paragraph from the evidence of Captain Flover, who mentioned that telegraphic communication would have been the means of saving hundreds of lives. The superintendent of the telegraph department of Lloyd's gave a number of instances in which telegraphic communication would have saved lives. In the case of the "Schiller," lost about 15 years ago, 331 lives were sacrificed, and the coroner's jury gave it as their opinion that if there had been electric communication the vessel would have been saved. He also mentioned a case off the coast of his own county where a vessel which was wrecked might have been saved if her state had been known in time. This system had been adopted in Canada, where telegraphic communication was used for commercial purposes, as well as in North Germany, where the lighthouses were connected with the shore, in Denmark, and, he thought, in Sweden and Norway. He was not anxious now to urge on the Government a great expenditure, but he wished to insist that the question should not be lost sight of. He hoped that they would hear that there would be a gradual extension of the system. The country at large was interested to an extraordinary extent a year or two ago in the subject of the saving of life at sea, and he ventured to think that, without incurring very large expense, communications might be established between certain prominent lightships and also outlying lighthouses and the shore by means of the appliances of modern science. He hoped the subject would be seriously considered by the Board of Trade, and that gradually and continuously the system would be extended.

The **Earl of Onslow** remarked that the subject to which the noble earl had called attention was one which interested a very large and important body in this country—namely, the mercantile marine. At the outset it was important to call attention to the terms of reference of the committee. It was appointed with the special object of facilitating the saving of life at sea, and the reason for that reference was that the funds which the Government were enabled to devote to that purpose could only be derived from one source, and that source was the Mercantile Marine Fund. Now by the Merchant Shipping Act of 1854 it was provided that the Mercantile Marine Fund

should be applied to the Local Marine Board and purposes connected with it, the expenses of surveys of steamships, expenses of lightship authorities, lighthouse and bullage of the Thames, expenses of wreck receivers, the preservation of life and property from and in case of shipwreck, any expenses specially charged by Act of Parliament, and "for no other purpose whatever." Therefore it was quite impossible to apply any portion of the Mercantile Marine Fund for the purpose of establishing electrical communication around our shores. If it was desired to do anything in that way in the interests of commerce, the fund must be provided by shipowners themselves or by the Post Office, who were bound by Treasury regulations to incur no expenditure which would not either prove remunerative or be guaranteed by those deriving benefit from it. Apart, however, from the question of cost there was a question of danger to the lightships themselves, because if masters were able to make communications with the shore through the lightships the number of vessels which would approach to the lightships would increase from an average of six to probably 20 a day, with the consequent risk that the lightships might be run down and a dangerous shoal or sandbank left absolutely unprotected. It was the duty of the Board of Trade and the lighthouse authorities to see that expenditure for this purpose was devoted in the first place to the prevention of wrecks, and not to offering temptations for lightships being approached for signalling purposes. A few years ago the lighthouse dues were very largely reduced, and the bad trade had caused a further falling off. The consequence was that in 1896 it was found necessary to borrow for the purposes of the Mercantile Marine Fund the sum of £250,000 from the funds of Greenwich Hospital. In 1896-7, £100,000 of that sum had to be expended in order to make up a deficiency between receipts and expenditure. Taking the accounts for 1896-7, the last completed, as representing the annual expenditure and as a basis of comparison, the deficiency might be taken at £160,000, being £69,000 in excess of dues for maintenance of lighthouses and new works, and £92,000 in excess of income upon other branches of the service—namely, mercantile marine offices, surveys of ships, expenses of saving life on the coast, and relief of distressed seamen abroad. The receipts from light dues had increased by £12,000, but as the accounts of the lighthouse boards for only six months for the current year, 1897-8, had been as yet received, he had obtained from those boards an estimate of their expenditure for the succeeding three months to December 31, 1897. This information led to the conclusion that the deficiency for the whole year 1897-8 might possibly not exceed £110,000. During the last ten years there had been an average of about £50,000 expended on new works. In the unfortunate state of the Mercantile Marine Fund the Board of Trade had none at all they could to reduce the expenditure on new works but they had not been able to reduce it below £85,800. The reason of this was that in these days shipowners, and perhaps shipmasters, were tempted to drive their ships by lights instead of, as in times past, navigating them by the lead. Consequently demands would continue to be made for illuminants of higher powers, for fog signals emitting increased volumes of sound, and other appliances which inventors were not slow to urge the Board of Trade to adopt. As things were, the means of signalling ships coming to our ports were very considerable, and shipowners had no great difficulty in obtaining early information regarding the approach of their vessels. It was a difficult and expensive task to establish communication between isolated rocks and the mainland, but experiments were now being carried out by Lloyd's in this direction, and if those experiments were successful, there was reason to hope that the system of communication between outlying rocks and the land might be very largely made use of. For vessels coming up the east end of the Channel there were ample means of communication, as there were stations at Dungeness, Beachy Head, two at Dover, and one at Deal while it was under consideration whether there should not be another at the North Foreland. Vessels approaching the Thames from the north were reported at Southern Pier, and it was contemplated to establish a station at Orfordness, where vessels approaching the Thames could hardly miss. For the east coast north of the Thames there were Flamborough, Yarmouth, Grimsby, and Aldborough. With regard to the experiments which had been made at the Sunk Lightship, they had been, very costly. The ship cost £7,000, without the fog signals; but for the purposes proposed this vessel would be too small, and it would be necessary to build another costing £8,000, while the cost of maintenance would amount to £2,420 a year, exclusive of £4,000 for the cable. What had been the practical results of the Sunk experiments? Since its establishment the ship had only called the lifeboat out seven times by telegraph, and on every one of these occasions the lifeboat had been apprised earlier by the rocket signals. It must be remembered that it was not possible always to have a man watching the shore end of the cable, he might be in bed, and only be called up by the ringing of the bell, and then he would have to go out to give the message. It was true that there was one advantage of communication by cable—namely, that it might prevent the lifeboat from going out on a futile errand after the wreck had been got off, but he must point out that the lifeboat men were paid for every time they went out, 10s. in the day, and £1 at night. It had been argued that by having cable communication, those on shore were able to know the exact locality of the wreck, but it must be remembered that rockets were fired in the direction of the wreck, and consequently the lifeboat men were able to form an accurate idea as to where the wreck was lying. It might be the case that cable communication would have been of advantage in the case of the "Deutschland" and the "Indian Chief," but there the want had been not so much of communication between lightship and shore, as that there was no ship at all at the most important point. Since that time a ship had been placed there, and only one casualty had occurred since. To establish cable communication was a very expensive matter. A light cable chafed, while with a heavy one there was the risk of the ship's anchor fouling it, and the ship sheering on to the lightship and causing it considerable damage. The experiments, there-

fore, at the Bank hardly justified further expenditure in the same direction. The Mercantile Marine Fund was in a state approaching bankruptcy, and could not be saddled with further burdens, while shipowners were not ready to come forward themselves. Lloyd's and the *Shipping Gazette* had done much to prevent loss of life at sea by supplying early information, and he trusted that the Bill shortly to be introduced by Lloyd's might pass through Parliament that Session, at all events, it would meet with no opposition on the part of the Government. He held that it was the duty of the Government with respect to this question rather to prevent wrecks than to give information after they had taken place, to spend their funds upon maintaining the efficiency of our existing lightships, and then, if anything further was possible, to increase the number of these ships. He could not, therefore, hold out to the noble earl that there was any chance of the Government taking up this question at present.

The **Earl of Crawford** said that he had been disappointed in the report which had been sent to the Board of Trade by the committee appointed to consider the question of saving life at sea, and he had himself desired to send a fuller report, recommending that further experiments should be carried on, but in a different manner. He was, however, bound to be guided by the opinion of the remainder of the committee, and he had therefore been unable to give effect to his views. He was all the more pleased, therefore, that their lordships' attention should be called to this subject. He agreed with the noble earl opposite that the committee had been rather too guarded in the expression of their views. There had been several matters which they had wished to recommend, but they had been informed that the present state of the funds at the disposal of the Board of Trade prevented any possibility of carrying out such suggestions. He believed that much would be done by the Bill which Lloyd's had promoted last session, in which they engaged to transmit information of wrecks to the nearest lifeboat station. He was happy to say that the experiments which had been tried showed that it had been found possible to maintain electric communication between the shore and the lightships. These experiments had been continued throughout the winter with the most satisfactory results. The noble earl had said that the cost of maintaining that communication was very great; but, on the other hand, the value of service rendered by means of that communication ought not to be overlooked. He thought that it would be in the interests of the lightships themselves that they should be of a larger type. It had been found that, while the men on board the lightships off the coast of Ireland could see for miles around them, at night the coast was hidden by fog, and no signals made on the ships could be seen from the shore. In these circumstances telephonic communication between the ships and the shore would be of the utmost value. He did not advise that lightships should be made the medium of communication between passing vessels and the shore, because that might lead a vessel into too close proximity to the lightship, and thus cause danger to both. Lightships were placed in their positions for the purpose of warning vessels to keep away, and not for the purpose of attracting them into positions of danger.

Earl Granville said that there had been too many objections—good, bad, and indifferent—offered by the noble earl in his reply to the observations of his noble friend. He was aware that the Government were exercising the strongest possible supervision over the expenditure of the country, but at the same time, in the matter of saving life at sea, he thought, even if the Mercantile Marine Fund was, as had been alleged, almost insolvent, the difficulty of want of funds for that purpose might be overcome by making an application to Parliament. It was stated on behalf of the Government that experiments had been tried with regard to electric communication between the shore and lightships, and that it had been found impossible to keep the cables in continuous good working condition. He understood, however, that the noble earl who had last spoken took exactly the opposite view of the matter, and that the experiments had proved successful. However that might be, the experiments ought not to be dropped, and he hoped that the Government would give the House an assurance that they would consider the subject further instead of finally putting it on one side.

TELEGRAPHISTS.

Mr. O. V. Morgan asked the Postmaster-General, on Tuesday, whether there were at present in the metropolitan districts twenty-five first-class telegraphists, whose length of service ranged from eighteen to twenty-four years who had been waiting at the maximum of their class since April, 1886, whether it was his intention to increase the senior class so as to relieve the congestion which at present existed, and which must necessarily increase yearly as others arrived at the maximum; whether, in the Central Office, the number of senior telegraphists was 161, as compared with 354 first-class, while in the metropolitan districts the numbers were sixteen and sixty-one respectively, and whether he would take the necessary steps to remedy the inequality?

In reply, **Mr. Ratkos** stated that the number of the first-class telegraphists in the metropolitan district who have attained to the maximum of their scale of pay is 24, and they reached their maximum in 1886. Of these 24 officers, 15 have completed 18 years of service and nine have not. The numbers of the respective classes are as stated by Mr. Morgan. The difference is due to the comparatively much larger number of superior duties performed in the Central Telegraph Office. The numbers of the classes both in the Central Telegraph Office and in the metropolitan district are fixed strictly in accordance with the numbers of superior duties to be performed, and as there are at present no additional duties of the kind to be provided for in the metropolitan district, he did not feel justified in making an addition to the senior class.

Mr. Tuite asked the Postmaster-General whether he could now state if the estimate of £40,435 for the first class at the Central Telegraph

Office for the past financial year was not realised by over £7,000, whether there were over 100 vacancies in that class, and whether he would consider the desirability of utilising the whole of the estimate of £41,252 for the current financial year by at once filling up those vacancies.

In reply, the answer given a few days ago was repeated, that the charge for the salaries of telegraphists of the first class at the Central Telegraph Office in the past financial year will not fall short of the estimate to the extent of £7,000. There are at present 70 vacancies in the class. As regards the current financial year, promotions will be made in due course, and that the expenditure for salaries of telegraphists at the Central Telegraph Office will approximate very closely to the estimate.

COMPANIES' MEETINGS.

SUBMARINE CABLES TRUST.

The seventeenth annual general meeting of the certificate holders of the Submarine Cables Trust was held, on Tuesday last, at the Winchester House, Old Broad Street.

Sir James Anderson presided, and in moving the adoption of the report stated that the revenue for the financial year ended the 15th ult. has been £17,948 as against £14,528 for the previous year, but in 1887 they brought into the accounts £2,140, whereas they began the year under review with only £96. In both years they had paid their coupons at the rate of 4½ per cent., but they carried forward to the current year a balance of £1,448, which was equal to an additional 8s. 6d. per cent. The interest payable on their certificates was cumulative, but their revenue had not enabled them to pay the coupons beyond those due on October 15, 1887, leaving the last coupon in arrears. If they distributed at once the balance of 8s. 6d. per cent. which they had in hand, the April coupon would have to be paid in three instalments, because in October next they would not have sufficient funds to pay the whole outstanding £2. 11s. 6d. To avoid the inconvenience of paying one coupon by three instalments, the trustees proposed, with the approval of the certificate holders, to hold the money in hand until October 15, when they would pay £2. 10s., and the balance of 10s. would be met on January 15, 1889. On April 15 next year they would pay as much as possible on the October coupon. The falling off in their receipts in the past year had been mainly owing to their investment in Anglo-American Company's stock. The Eastern and Eastern Extension Companies, however, in which they held a large amount of stock, were paying very fair dividends, and by that fact their revenue was maintained better than might be expected. Eventually, if all the Atlantic cable companies came to some agreement, the Company would be in an improved position.

Vincent Monck seconded the motion, which was carried unanimously; and the auditors were afterwards re-elected.

MAXIM-WESTON ELECTRIC COMPANY.

An extraordinary general meeting of the Maxim Weston Electric Company, Limited, was held last Thursday at the City Terminus Hotel, having been convened by the Chairman of the Company, Mr. Hugh Watt, M.P., "to elect two additional Directors and to fix the remuneration of the Board."

Mr. Watt took the chair, when the question of the validity of the meeting was at once raised and was warmly contested, the Chairman referring to a legal opinion which he had obtained on the question, and **Mr. J. M. Klenck**, **Mr. John Newton**, and other shareholders disputing the point.

The Chairman, after considerable discussion, stated that though he held an overwhelming majority of proxies which would carry any resolution he might put, he was quite willing not to use them if the shareholders thought that the meeting was irregularly constituted. He was, he said, most anxious to promote the interests of the Company, in which he stood to lose between £4,000 and £5,000.

Eventually, further discussion arising as to the legality of the meeting, and the proceedings becoming uproarious, the Chairman declared it dissolved.

A meeting of the shareholders was afterwards held, Mr. Klenck in the chair, but the reporters were asked to withdraw.

From a letter by Mr. W. Klenck, sent to the *Financial News*, we gather that, after Mr. Watt had vacated the chair, it was resolved to lodge a requisition with the Company to call an extraordinary general meeting of the shareholders. The requisition was opened, and a numerous shareholders representing a large part of the capital of the Company.

PROVISIONAL PATENTS, 1888.

APRIL 27.

6237. Improvements in jars or cells for primary or secondary electric batteries. Adam Miller, 62, St. Vincent street, Glasgow. (Complete specification.)

6270. Improvements in clips for attaching or fixing insulators to telegraph poles. Howard Graham Johnson, 7, St. James's, Manchester.

APRIL 28.

6314. Improvements in or relating to dynamo-electric machines. Joseph Platt Hall, 17, St. Ann's square, Manchester.

6322. Improvements in galvanic batteries. Paul Ravi & Fauchaux d'Humy, 23, Southampton-buildings, Manchester.

6344. An improved means of conveying telegraph, telephone, and similar wires. Walter Davies, 54, Fleet street, London, E.C.

APRIL 30.

6373. Improvements in electric batteries. Louis Dill, Berlin, Germany, 38, Alexander Str.
6382. An improved electric automatic delivery box. William Miller, 13, Camera square, Chelsea.
6390. Improvements in electrical switches. William Mackie and Sidney Sharp, Connaught Mansions, Victoria-street, London, S.W.

MAY 1.

6416. Improvements in galvanic batteries. Louis Hoppe and Guntner Hoppe, 6, Annette road, Lorraine-road, Holloway, London, N.
6481. Improvements relating to the electrical transmission of power, and to apparatus therefor. Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.) (Complete specification.)
6502. Improvements relating to the generation and distribution of electric currents and to apparatus therefor. Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.) (Complete specification.)

MAY 2.

6578. Improvements in incandescent electric lamps. James Yate Johnson, 47, Lincoln's inn fields, Middlesex. (Charles Philippart, France.)

MAY 3.

6609. Improvements connected with mechanical telegraphs for use in navigable vessels. William Chadburn, 15, Water-street, Liverpool.
6610. Improvements in and connected with pneumatic telegraphs for communicating between one position or station and another or others on navigable vessels and other structures. William Chadburn, 15, Water-street, Liverpool.
6613. Automatic resistance for electric-light circuits. Samuel Meier, 1, Langton Cottages, Melbourne square, Brixton-road, S.W.
6614. Improvements in the electrical illumination of clock dials and apparatus in connection therewith. Ernest George Craven, 4, Little Moorfields, E.C.
6617. An improved method of printing from strips of electrotype or stereotype, and of adjusting and fixing the same upon printing blocks. John Bell Allen, 2, Gresham-buildings, Guildhall, London.
6627. A combined generator of electricity and electric lamps. George Antoine Tabourin, 4, South street, Finsbury, London, E.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MAY 18, 1887.

7235. Improvements in the safety mechanism or cut out of electric arc lamps or other electrical apparatus. Frederick Carrington Phillips and Hugh Erat Harrison, 2, Victoria Mansions, Westminster.

MAY 28, 1887.

7834. Improved means for controlling, transforming, regulating, synchronizing, and registering electric currents. Henry Edmunds, 47, Lincoln's-inn fields, London, W.C.

JUNE 8, 1887.

8214. Improvements in telephone systems. William Phillips Thompson, 6, Lord-street, Liverpool. (Emil Mauritius, Germany.)

JUNE 29, 1887.

9256. Improvements in and apparatus for regulating the speed of dynamos employed on railway trains for lighting the same. Judah Levy Yuly and Herbert Walter Andrews, 9 and 10, Southampton-buildings, W.C.

JULY 2, 1887.

9396. An apparatus for preventing or detecting the use of pieces of lead, iron, or other similar or extraneous substances instead of coin in operating automatic weighing, measuring, strength-testing, electric, or other automatic supply machines. William Ernest Richardson, 19, High-street, Sheffield.

SEPTEMBER 27, 1887.

- 13,069. Improvements in or relating to harmonic telegraphy. Francois Van Lysberghe, 433, Strand, London, W.C.

OCTOBER 17, 1887.

- 14,062. Improvements in automatic medical electrical apparatus. Edgar Pullar, Gray's Inn Chambers, 20, High Holborn, London, W.C.

NOVEMBER 14, 1887.

- 16,537. Improvements in electric switches. Robert William Paul, 10, Ravensdale-road, Stamford Hill, London.

DECEMBER 10, 1887.

- 17,047. Improvements in secondary batteries. Frank King, 47, Lincoln's-inn-fields, London.

JANUARY 4, 1888.

137. Improvements in apparatus for producing induced electric currents. John Charles Parthner, 12, Mariahilfer Strasse, Vienna, Austria.

FEBRUARY 29, 1888.

3076. An improved clutch for regulating feeding rods in electric arc lamps. Alfred William Southey, 1, Cullum street, City.

MARCH 2, 1888.

3215. Improvements in electric incandescent lamps. John Wm. Oldroyd, 8, Quality court, London, W.C.

MARCH 2, 1888.

3235. Improvements in multipolar dynamo-electric machines. George Miot, 46, Lincoln's inn-fields, London, W.C.

MARCH 20, 1888.

4277. Improvements in electro-mechanical movements. Alfred Julius Boult, 323, High Holborn, London, W.C. (James Francis McLaughlin, United States.)

APRIL 3, 1888.

4929. Improvements in magneto-electric generators. Webster Gillett and George Haseltine, 52, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1886.

- *2956. Electric motors and dynamo machines. M. Immiach. 8d. Amended specification.

1887.

6104. Electrical measuring instruments. A. Le N. Foster and Andersen. 8d.
6219. Induction apparatus. J. Swinburne. 6d.
7184. Electric arc lamps. W. Mackie. 8d.
7950. Telephones. D. J. Smith and H. F. Jackson. 8d.
7892. Telephonic instruments. C. L. W. Fitzgerald. 11d.
8159. Electric telegraphic communication. W. Smith. 8d.

1888.

2179. Incandescent electric lamps. M. Wheeler. 6d.
2246. Dynamo-electric machines. H. H. Lake. (Eickemeyer.) 1s. 11d.
2250. Printing telegraphs. J. H. Lanville. 3s.
2308. Dynamo-electric machines. C. Coenper. 4d.

NEW ELECTRICAL COMPANIES.

United Kingdom Telephone Union, Limited.—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, London, E.C., without articles of association, and, therefore, the clauses of the first schedule of the Companies Act, 1862, will apply. Capital, £10,000,000, divided into 2,000,000 shares of £5 each. Object: To acquire upon any terms and for any purpose the whole or any part of the property, business, goodwill and undertaking of any company, association, or person in the United Kingdom, or elsewhere, carrying on, or in the case of a company or association formed or empowered to carry on, any business comprised within the objects hereinafter mentioned, and to undertake all or any of the liabilities or obligations, and to compensate any office, officer, or employee of any such company, association, or person, to acquire and hold or dispose of the whole or any part of the shares, stocks or obligations of any company, any property of which shall be acquired by the Company, or which may be carrying on any business, or formed or empowered to carry on any business, comprised in the objects of the Company; to acquire and exercise any patent rights, privileges, licenses or monopolies relating to telephones or any telephonic apparatus, to take and work any license for the use of any invention which may be capable of being used in connection with any business of the Company. The first subscribers are:—

	Shares.
J. Brand, chairman of the United Telephone Company, Limited, New Broad-street, E.C.	1
J. S. Forbes, deputy-chairman, Garden Lawn House, Chelsea Embankment, S.W.	1
J. Thompson, chairman of the Lancashire and Cheshire Telephone Exchange Company, Limited, Riversdale, Wilmslow	1
R. N. Jackson, chairman of the National Telephone Company, Limited, Ashurst, West-Ind, Sydenham	1
J. Winstanley, chairman of the Telephone Company of Ireland, Dondrum, co. Dublin	1
D. Bateson, chairman of the South of England Telephone Company, Limited, 77, West Cornwall-road, S.W.	1
C. Nash, chairman of the Western Counties and South Wales Telephone Company, Limited, Down-square, Bath	1
R. T. Wilkinson, chairman of the Northern District Telephone Company, Rose Dene, Sunderland	1
J. B. Morgan, A.I.C.C., managing director of the United Telephone Company, Limited	1

CITY NOTES.

Personal.—Mr. Basil Gee has taken charge of the London sales department for wire and cable of Walter T. Glover & Co., 10, Hatton-garden, E.C., and Salford.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended May 4 amounted to £4,387.

Eastern Telegraph Company.—The Eastern Telegraph Company's traffic receipts for the month of April, 1888, amounted to £51,582, and to £43,136 in the corresponding period of 1887.

South of England Telephone Company.—The Directors of the South of England Telephone Company, Limited, have declared a dividend of 6 per cent. per annum on the preference shares for the half-year ending April 30.

West Coast of America Telegraph Company.—The traffic receipts of the West Coast of America Telegraph Company for the month of April amounted to £4,325, and those of the Direct Spanish Telegraph Company to £1,800.

Direct Spanish Telegraph Company.—The estimated traffic receipts for the month of April of the Direct Spanish Telegraph Company, Limited, were £1,800, against £1,681 in the corresponding period of last year, showing an increase of £119.

Great Northern Telegraph Company.—The traffic receipts of the Great Northern Telegraph Company for April were £21,400, making a total from January 1 to April 30 of £85,200 against £81,520 and £78,480 for the corresponding months of 1887 and 1886 respectively.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ended May 4, after deducting the fifth of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, were £3,649.

Eastern Extension, Australasia, and China Telegraph Company.—The traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company, Limited, for the month of April, 1888, amounted to £37,331, and to £35,955 in the corresponding period of 1887, an increase of £1,376.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company, for the half month ending April 30 were £3,268, against £3,027 for the corresponding period of 1887, the January receipts estimated at £3,718, realised £5,955.

Consolidated Telephone Construction and Maintenance Company.—The Directors of the Consolidated Telephone Construction and Maintenance Company, Limited, recommended a dividend at the rate of 25. 7s. per cent. per annum for the year ending March 31, inclusive of the interim dividend paid in November last.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Company during April was 4,684, estimated to produce £3,700, against 3,823 messages producing £2,964 in the corresponding month of last year. The traffic receipts for January, estimated at £3,300, realised £3,366.

Oriental Telephone Company.—At the adjourned meeting of the shareholders of the Oriental Telephone Company, Limited, to be held on Friday, the 25th inst., the proposed dividend of 2½ per cent. free of income-tax, for the past year on the paid up capital of the Company other than the vendors' shares will be again recommended by the Directors.

Newton's Syndicate.—It is reported that Mr. Newton's New Electric Light Syndicate have entered into arrangements with Colonel J. T. North, to dispose of Mr. Newton's patents to a joint stock company with a capital somewhere in the hundred thousands. Electric lighting is about the only branch of industry in which the indefatigable Colonel has not yet embarked.

West India and Panama Telegraph Company.—The report of the Directors of the West India and Panama Telegraph Company, Limited, for the half year ended December 31, shows an available revenue balance of £21,857, of which £5,000 has been carried to reserve. They propose to pay 10s. per share on account of arrears of dividend on the first preference shares, £1,606 being carried over.

London Platino-Brazilian Telegraph Company.—The report of the Directors for the past financial year states that the net revenue of the year, after providing for debenture interest and income-tax, is £10,925. 12s. 5d., and £1,543. 8s. 8d. is brought in from the preceding year's account, making a total of £12,469. 1s. 1d. to the credit of revenue account. The interim dividend of 2s. 6d. per share, paid on November 22, 1887 absorbed £4,793. 10s., leaving, therefore, to be dealt with £7,675. 11s. 1d., from which the Directors propose to appropriate £150 in further reduction of the item of expenses of issue of the six per cent. debentures, to add £1,000 to the reserve fund, and to apply £5,752. 4s. in payment of a final dividend of 3s. per share, making, with the interim dividend already paid, a distribution at the rate of 2½ per cent. per annum, as against 3 per cent. paid last year, leaving a balance of £773. 7s. 1d. to be carried forward.

NOTES.

Barcelona.—The illumination of the fountains at the Barcelona Exhibition has been placed in the hands of the Anglo-American Brush Company.

Brussels. The palace of the Comte de Flandre is now lighted by electricity by means of a Lahmeyer dynamo and a set of Julien accumulators.

Erratum.—In the article on "Double and Single or Earth-wire Systems," published last week, the dotted and solid lines in Fig. 1 should be reversed.

Olmutz.—The municipality of this town have resolved to establish an installation of electric lighting in the theatre there prior to the opening for the new season.

Death by Electricity.—The New York Assembly passed the Bill substituting electricity for the halter in the case of criminals sentenced to death, by a majority of eighty-six to eight.

Glasgow Exhibition.—This exhibition was a model of punctuality—not only the machinery and all the electric light being quite ready, but also practically the whole of the private exhibits.

Electrical Watches.—A company has been formed in Berlin to manufacture electrical watches. Two small cells and a small electric motor take the place of the ordinary movement.

Railway Lighting on the Continent.—The electric light is being used for trains on the Wurtemberg railroads, on the Novara-Seregno road in Italy, and on the Russian South Western line.

Owens' College.—Prof. A. Shuster, Ph.D., F.R.S., has been appointed to the Langworthy Professorship of Physics and directorship of the Physical Laboratory at Owens' College, in succession to the late Prof. Balfour Stewart.

Verona.—The local company formed to establish a central station of electric lighting being unable to carry the project into effect, the shareholders in the gas company have authorised the latter to execute the work in question.

Paris. It is stated that the Paris Municipal Council intends to request the companies at present distributing electrical power by means of overhead wires to conform to the terms of the conditions of contract now being published in our columns.

Brixton. We understand that the new road at Brixton, Palmerston-avenue, is to be lighted up by the electric light on the Fyfe main system. These are the sort of items we have to report, as against the continued items of whole towns being lighted in America.

Honolulu.—The town of Honolulu, Hawaii, has been lighted with electric light, supplied by the Thomson-Houston Electric Company, of New York. There are 62 arc lights, and the dynamos are driven by water-power with 300ft. head, $2\frac{1}{2}$ miles from the city.

Society of Telegraph-Engineers.—An extraordinary general meeting of the society will be held on Thursday, 24th inst., when Sir W. Thomson, L.L.D., F.R.S., Past President, will read a paper on his "new Standard and Inspectional Electric Measuring Instruments."

Electric Firearms.—The latest novelty is the employment of electricity instead of percussion caps for firearms.

The spark is produced in the same manner as the now well-known gas lighters, and it is claimed that by this means a more powerful explosive than gunpowder can be used.

Brussels Exhibition.—The Brush Company have taken the contract for lighting the British section at the Brussels Exhibition with supply of current for incandescent lamps for exhibitors and restaurateurs. They are also lighting the hippodrome arena with arc lights, and have a 6 light mast at the entrance.

Motor Cars.—After much experimenting with various motors, St. Louis, U.S., has finally adopted electricity as the motive power for their roads, with Julien storage batteries and Brush motors. The contract for the Fourth Avenue, New York, has been taken by the Julien Company, and the price is 40 per cent. below that of horses.

New Technical Schools.—Blackburn is going to spend £25,000 on building a technical school of most approved construction. Mr. E. G. Robins, F.S.A., the well-known expert in technical colleges, had the selection of the design, which was won by Messrs. Smith, Woodhouse, and Wolloughby, 100, King-street, Manchester.

Eastbourne. A memorial was received last Monday by the Eastbourne Town Council from the inhabitants of the Royal Parade, calling attention "to the great existing want of the electric light on the Royal Arcade." At present the gas lamps are not in keeping with the electric lights on the Grand Parade. The matter was referred to the Lighting Committee.

True Burglar Alarm. Instead of a small bell placed near the bed to wake the occupier, by far the better way, it is suggested, will be to connect the doors and windows with a good 18in. gong in the hall; then, instead of the master of the house having to come down to persuade the burglar to go, the burglar departs of his own free will—for what burglar would stay to burgle with an 18in. gong going?

Electrical Tramway for Leamington.—An experiment is about to be made at Leamington in electrical tram-cars. The Milverton Local Board have given their sanction to the project, and its introduction is looked forward to with exceptional interest. It is believed that the intention of the promoters is to utilise the electricity generated during the day in connection with the Midland Electric Lighting Company.

Royal Society.—The following papers were read at the Royal Society on Thursday, May 17:—Prof. J. Burdon Sanderson, F.R.S., "On the Electromotive Properties of the Leaf of *Dionaea* in the Excited and Unexcited States, No. II."; Prof. Ewing, F.R.S., and G. O. Cowan, "Magnetic Qualities of Nickel"; Prof. J. O. Ewart, "On the Structure of the Electric Organ of *Rana* circularis."

New Siemens and Halske Dynamo.—In a new type of dynamo machine constructed by this firm, the field-magnet, of four branches, is placed within the circumference of a Paccinotti ring, the magnet being stationary, and the ring revolving about it. One of the experimental machines on this type, weighing less than 13cwt., and running at 350 revolutions per minute, gave a power of 16,000 useful watts, whilst at 480 revolutions the power rose to 25,000 watts.

A New Lamp Factory. A new manufactory for incandescent lamps has been started at Stockholm, Mr.

R. W. Strehlenert having removed to this town from Sodertelge, where for a couple of years he has been engaged in connection with this manufacture. Mr. Strehlenert has succeeded in securing an able staff of men, and is at present turning out some 600 or 700 lamps a week, which number, however, can be raised to 2,000 a week if required.

Hastings.—We are glad to note that the Hastings Electric Light Company's report, just issued, shows that the directors will be able, at the sixth annual meeting of shareholders on the 22nd inst., to recommend a dividend of 3 per cent. The tide at last has apparently turned with this pioneer company. Most of the principal hotels are now using the light, and many further applications are being made, and we may evidently look for continued progress and success.

Bicycle Papers Please Copy. The bicycle manufacturers in America are introducing the process of electric welding by the Thomson Houston process into their works. A delegation of makers recently made a visit to the Thomson-Houston factory and witnessed trials of the process, which were very successful. We believe that the whole process of Thomson Houston welding is in the hands of the well known electrical engineers, Laing, Wharton and Down, in this country.

Relative Cost of Electric Light.—The following significant figures are taken from a report sent to the Corporation of Chicago by Prof. Barret. They compare the annual price of maintenance of the electric light with that of gas, taking into consideration all expenses, fuel, interest, depreciation, and repairs, &c. Gas: 3,273 burners, 52,368 candle power, £13,053. Incandescent lamps: 3,273 lamps, 98,190 candle power, £8,900. Arc lamps: 750 lamps, 1,500,000 candle-power, £7,475.

Tempering Magnets. A combined process for tempering and magnetising steel bars for magnets is employed by M. Ducretet. He employs a water tight vessel, at the bottom of which are two soft iron pole pieces; the poles of a powerful electro-magnet are placed underneath these. The vessel is partly filled with water, and a layer of oil is above this. The red-hot bar is passed through these; its passage first through the oil is found to soften the steel without depriving it of its power of being magnetised.

Testing Water. It has long been known that if a voltmeter is filled with perfectly pure distilled water it is impossible to pass an electric current through it. If, however, a few drops of acid, or a small quantity of soluble salt, is dissolved in the water, the current passes and electrolysis takes place. Dr. Carpené has proposed to make use of this fact to determine the quantity of a given impurity contained in water, as experiment shows that at a given temperature a definite quantity of any substance must be dissolved in the water before the current will pass.

The Advantage of Electric Trams.—Colonel Henry Flad, one of the foremost engineers of America, at present head of the St. Louis Board of Public Improvements, recommends the use of electric rather than cable tram-roads, except for very steep gradients. The chief advantage in his eyes is that each storage car is an independent unit. "The importance of this, particularly in large cities and with long lines, cannot be over-estimated; and I would recommend the electric motor, with storage batteries, even if a cable road could be constructed and operated at less expense."

The Paris Exhibition. We have much pleasure in stating that Mr. John Aylmer, of Paris, has been appointed by the Executive Council of the Lord Mayor's Committee for carrying out the English Section of the Paris Universal Exhibition of 1889 as their hon. secretary in Paris. The success which attended Mr. Aylmer's management of the Paris Electrical Exhibition of 1881 (where he acted as secretary to the English Commission) will no doubt be repeated next year in the larger undertaking, and we can congratulate the executive in having secured the services of such an able and zealous official.

A New Insulating Compound. A very valuable insulating material, described in the *Chronique Industrielle*, has just been produced. It is composed of one part Greek pitch and two parts burnt plaster, by weight, the latter being pure gypsum, raised to a high temperature, and plunged in water. This mixture, when hot, is a homogeneous, viscous paste, and can be applied with a brush, or cast in moulds. It is amber-coloured, and possesses the insulating properties of ebouite, and can be turned and polished. Its advantage is its endurance of great heat and moisture without injuring its insulating properties.

Bradford.—The Corporation at Bradford have unexpectedly encountered an obstacle in their lighting scheme. They thought only to ask and have the necessary sanction from the Local Government Board for borrowing the money; but it is found that a local inquiry must be held, and the whole affair is to be fully considered at Whitehall. Moreover, the tenders are so numerous and various as to give rise to the suggestion that the specification was too vague, and it has been alleged that economy was not kept in view among other things, that an odd gauge of wire for the cables was specified, which is not kept in stock by manufacturers, and would have to be drawn specially. Meanwhile the whole thing hangs fire.

Herr Hempel's Micro-Telephone Station.—Herr Alwin Hempel, of Dresden, has invented a micro-telephone station, in which the microphone is so extremely sensitive that it reproduces the most softly whispered tones. The reproduction of the spoken voice is so exceptionally loud that even deaf people can avail themselves of Herr Hempel's apparatus, which can, moreover, be employed for the transmission of music. More than 100 telephones can be connected with a single one of these microphones. Herr Alwin Hempel is in possession of a testimonial from Prof. Dr. Kohlrausch, one of the first authorities upon electro-technical matters in Europe, who states that he knows of no microphone station which works better than that patented by Herr Hempel.

Licenses to Electric Light Men. In Boston, U.S., an electrical exchange has been established to issue licenses to men engaged in electric light work. It is expected that the institution, properly conducted, will prove of great advantage to both men and companies. The licenses are divided into five classes. First class, to instal and operate any electric light and power plant; second class, to instal and operate any two of the following—viz., incandescent, arc lights, or power; third class, to instal and operate any one of the above; fourth class, to operate electric machinery, but not to instal; fifth class, to do electric wiring, but not to operate electric machinery. The New England underwriters have expressed their willingness to co-operate with the electric light men in licensing employees.

Lightning Express.—"Electric Expressage," invented by David G. Weems, of Baltimore, is one of the latest developments in rapid transit schemes, and by means of which newspapers, mail matter, and express packages will reach Chicago from New York in about two hours, and in seven hours more the "matter" would reach San Francisco, Cal. This car will travel at the rate of nearly four hundred miles an hour on a light elevated railway, and will run automatically, just the same as some of the cash-carriage contrivances used in large stores; and the system is in some respects similar to the Adams' elevated railway, only on a much smaller scale. The Electric Automatic Transit Company has been organized to build a test line in Washington at once, and a line is to be constructed in Maryland in a few months. —*Chicago Street Railway Gazette.*

Voltmeters and Ammeters by Repulsion.—The volt- and ammeters made by the Waterhouse Electric and Manufacturing Company are constructed on the principle of electro-magnetic repulsion, which is a constant with equal current. Heretofore such instruments have been made to act by means of a permanent magnet, or in their construction a coil spring has been used, so that the magnetism of the magnet, or the resilience of the spring has been a varying quantity, and frequent calibration has been necessary to correct these variations. The Waterhouse instruments are calibrated by the Cornell University standard, and once adjusted remain in adjustment. An ammeter may be left in the circuit with the current continually passing through it, but its adjustment is unchanged. The instruments are very sensitive to variations of the current transmitted through them, and are not only adapted to electric light stations, but also for the finest laboratory tests. The company also make a very fine galvanometer and other delicate instruments.

Extension of Motors.—"The day is not far distant," says Mr. Franklin Leonard Pope, in an interesting and valuable paper in a recent number of *Scribner's Magazine*, "when rapid transit between the principal cities of America will be effected to an extent which to persons unfamiliar with the developments of electricity must seem utterly visionary and chimerical. Once admit, as we must do, the possibility of applying almost limitless electric power to each axle of a train, with the possibility of laying a track almost as straight as the crow flies from city to city, rising and falling as the topography of the country may require, and the complete solution of the problem becomes little more than a matter of detail. Not that such detail is unimportant, nor that the innumerable minor difficulties can be overcome without much experiment and study; but it may, nevertheless, safely be affirmed that the ultimate result is already distinctly foreshadowed, and that we may expect within a few years to be transported between New York and Boston in less than two hours, not by the enchanted carpet of the 'Arabian Nights,' but by the potent agency of the modern electric motor."

Cloud Telegraphy A remarkable experiment in signalling with electric lights was recently made by the officers of two vessels of the British Navy, the *Orion* and the *Espoir*, off the port of Singapore. The *Espoir* had sailed from that port for Hong Kong, leaving the *Orion* in the harbour of Singapore. When the *Espoir* was sixty miles distant, the *Orion* sent her a message by throwing a brilliant light upon the clouds, and the reflection of this was seen distinctly by those on board the

Espoir, and by this means a regular message of alternate long and short flashes was read and understood by the *Espoir*. The practical use of cloud telegraphy as a recognised means of communication would probably be confined to special circumstances, and would, of course, depend upon the state of the weather, but the possibility of communicating a distance of 60 miles at night without wire is very important. The first application of such a means of telegraphing which suggests itself is that of lighthouses, whose lights could be rendered visible to a much greater distance on cloudy nights if provided with an apparatus for flashing on the clouds. The reflections often seen at night from the blast furnaces in some of the large manufacturing towns are visible to a great distance, and give some idea of the effect of the electric light upon the clouds.

Incandescence Lamps v. Fire Risks. The results obtained in the experiments with incandescence lamps recently made by M. Mascart point to the necessity in certain cases of increasing the size of the glass containing vessels, so as to increase the area through which heat may be dissipated by conduction. Lamps of 12 or 16 c.p. would no doubt be perfectly safe; but two of M. Mascart's 32-c.p. lamps carbonised the wadding with which they were surrounded, and, ultimately bursting, set fire to the charred material. A third lamp of the same c.p. destroyed the double thickness of cotton fabric in which it was enveloped, but without setting fire to it. Silk was destroyed in the same way, and commenced slowly to burn. A similar lamp produced no effect in 30 minutes when placed in a fold of old scene-canvas; but with a lamp of 300 c.p. the material was charred, and commenced to burn, without flame, in one and a half minutes. We should be interested to know the size of the last-mentioned lamp. We have seen a 100-c.p. incandescence lamp within a glass vessel but little larger than that surrounding an ordinary 16 c.p. filament. One of these has been known to completely char the wood of its holder, and actually melt the glass of its own bulb; and it is probable that M. Mascart's 300-c.p. lamp was constructed without any precaution to provide for the dissipation of the comparatively large quantity of heat generated in a given time.

The "Telegraphist." After a struggle of four years the *Telegraphist* has ceased to exist. It is as characteristic of the Englishman not to support his professional paper as it is with the Americans to do the opposite. We presume that although the editor in his "farewell" speaks of a support of 50 per cent., if he had received the support of half that number it would have satisfied him, and carried him and his paper on to success. The great branch of applied electricity—hand telegraphy—is now unrepresented, unless, indeed, our contemporary the *Telegraph Journal* sees fit to devote more attention to the subject indicated under its older title; but we doubt if such will be the case, as its proprietors long since found—and as Mr. Lynd has more recently found—support will not be forthcoming from those who are most directly connected with telegraphy. We admire the pluck with which Mr. Lynd has stuck to his task, and regret such determination has had no better ending. Of course, one great deterrent to the success of such a paper exists in the fact that telegraphy being under Government control, there is no great incentive for advertisers to advertise—at least, that is how they look at it. On the other hand, those more or less behind the scenes know that the conclusion is absolutely incorrect; besides, it should be noted that every railway deals largely

with telegraphic apparatus. But this business runs somewhat in a groove; a firm gets the orders of a particular railway and looks upon that success as sufficient, troubling no further, so year after year the orders go in the same directions, and all men connected therewith are pleased.

Wimshurst Machines. At the Royal Institution, London, lately, Mr. James Wimshurst delivered a lecture on electrical machines. The audience was large, because Mr. Wimshurst's name is known wherever electrical machines are used, and it was known that there would be something magnificent to see. The lecturer passed briefly over the history of the subject, but showed a working model of the parent of all the modern machines, which was invented by Nicholson one hundred years ago. He said but little about the theory of machines; indeed, he seemed rather sceptical when he spoke of theory at all, an attitude which he may be excused for taking, for he quoted at length a statement made by Sir William Thomson when the Holtz machine was invented, according to which that machine was successful beyond all expectation, because Holtz had discarded metallic carriers and contact brushes. Now, the lecturer, not knowing the views of this distinguished physicist, did those very things which, according to this authority, he should not have done, with the result that he produced a machine far in advance of the Holtz in every way. He said that had he known what Sir William had written he would never have ventured in the direction he did, and the Wimshurst machine might never have been made. At the conclusion of the lecture he justified his eulogy of the machine which bears his name by treating the audience to a display of artificial thunder and lighting such as few, if any, of the audience had seen before. Indeed, had such machines existed before the time of Franklin, there would have been but little occasion to send up that historic kite, which proved that the puny sparks at that time obtainable were truly the same in kind as the lightning-flash.

Electrical Bullet Probe.—At a recent meeting of the New York Academy of Medicine, Dr. Gardner, of New York, exhibited his telephonic bullet probe. The following account of this apparatus, which we must confess is in great measure unintelligible to us, appears in some of the New York papers:—"The interesting feature of this probe is that it is operated by a current of electricity extracted from the body of the patient himself in whom it is desired to locate a metallic missile." (We suppose this means that the body of the patient constitutes the electrolyte of a voltaic couple, constituted by the probe and the "hollow bulbous piece of steel" mentioned below; although no intimation is given that one of these is electro-positive to the other.) "The construction of this probe is as follows: To each of the two terminals of a telephone receiver an insulated flexible wire about 4ft. long is connected. At the free end of one of these wires a hollow bulbous piece of steel is attached. At the free end of the other wire is a suitable handle, in which a probe may be placed, and held by a clamp screw. The internal arrangement of the handle is such that a perfect electrical contact exists between the end of the probe and that of the wire which terminates in the handle; the same is true for the end of the other wire and the steel bulb." (This, one would think, "goes without saying.") "When a current of electricity is passed through the coil in the receiver by means of the bulb and the probe, each time that the current is made and broken a clicking or rasping sound is heard in the receiver held to

the ear. All sounds are shut out except that heard when the bullet is touched [how about the clicking or rasping sound just mentioned?]; and the apparatus is so constructed that both hands are left free."

Gas v. Electricity. The *Bulletin International de l'Electricité* gives a possibly useful word of warning to those who might be inclined to understate the cost of lighting by electricity as compared with that of gas lighting. When extensive works, hotels, or shops have to be lighted, and it is practicable to install gas or steam engines and a dynamo machine on the premises, electricity, as in many cases has been proved, offers a real economy over gas. But it must be borne in mind that in these cases it is the *cost* price of the electrical power which is compared with the *selling* price of gas, which includes the profit of the gas company, besides the general expenses of production. This accounts for the fact that the economical advantage of electricity disappears, or at least is no longer so appreciable, when the supply takes place from a central station. We have, then, the selling price of electrical power compared with the selling price of gas. On the other hand, it is to be considered that improvement is naturally and continuously being effected in the production and in the supply of electrical power, and that theory, which is altogether on the side of electric lighting, is gradually being approximated to in practice. Theory clearly indicates that more light is to be obtained from a ton of coal by utilising it for the production of electrical energy than by employing it for the production of gas, due allowance being made for the value of the residual coke. Thus, a ton of coal utilised in good steam engines corresponds to 600 h.p. hours, and, consequently, to 5,000 lamp hours, of 16 candles, or 8,500 carcels. A ton of gas coal gives 300 cubic metres of gas, and 600 kilos of available coke; the former can produce 2,857 carcels, and the latter, consumed in the steam engine, 2,600 lamp hours of 16 candles, or 4,420 carcels. Thus, *a priori*, electricity has a luminous efficiency superior to that of gas of 1,200 carcels per ton of coal, or superior by 16 per cent. on a liberal theoretical estimate.

Telephoning to Trains in Motion.—M. Germain read a paper on April 23, before the Sociétés Savantes, Paris, describing a new system of telephonic communication between trains in motion and neighbouring signal boxes. In considering the application of electricity to the lines of railroads, M. Germain pointed out that, by reason of their *resistance* and *insulation*, the two lines of the same railway, connected together, constitute an excellent conductor when they are *part of a circuit not communicating to earth*, and when the battery is also well insulated from earth. He states that a new line has less resistance than an old line because of the oxidation of the fish plates, and of the alteration of the molecules of steel due to vibrations. Suppose a circuit constituted between two stations, 1st, by a wire suspended on posts, 2nd, by the rails coupled electrically. If a battery is inserted at one of the stations, and if a telephone is inserted on the train at a point in the circuit formed by the two last wheels of the guard's van, the guard plate, and the draw bars of all the carriages, the telephone will reproduce telegraphic signals given at the fixed station. The train may be running at its greatest speed, the signals are equally distinct. The telephone thus connected is in a secondary circuit, moving along the rails. The potential in both circuits is the same. The production of spoken words by two receiving telephones, one on the train and one at the station, is very feasible, but if the current of the battery is trans-

formed by means of an induction coil into a high-tension current, and a microphone of twelve carbons is inserted in the inducing circuit, words are then reproduced with remarkable clearness. By the simple device of a moving secondary circuit formed by the metal connections of the train, with the aid of a single wire placed below the ordinary telegraph wires, telephonic communication can be obtained with trains in motion. For trains in motion to communicate with the stations, two currents of equal intensity are set in opposition, one in the primary, the other in the secondary circuit. When the currents are equal, the telephone is silent; by interrupting the current in the moving secondary circuit, signals can be heard in the telephone. With similar apparatus to that at the station, in each guard's van, ordinary telephone communication can be established both ways. The telephone will not produce words clearly until a potential of 450 volts are attained—the quantity is about two to three milli-amperes. A battery of twenty cells, weighing altogether 132lb., giving normally 1.5 volts and six amperes per cell, is required for each station and for each train.

Long Distance Telegraphy.—The recently announced claim, says the *Scientific American*, of a telegraphic circuit of over 6,000 miles, surpassing all previous experiments, is somewhat misleading. Many efforts at long circuit work have occurred during the past few years, the distance varying from 4,600 to 8,100 miles. It is a matter of considerable pride to the old operators of the Western Union Telegraph Company in San Francisco, says the *San Francisco Alta*, that the feat of transmitting clock signals through 7,200 miles of line and communicating directly through that same line has never been equalled. The occasion of this feat was the telegraphic determination of the difference of longitude in time between the United States coast survey station in San Francisco and the observatory of the Harvard University at Cambridge, in the year 1869. In order to determine the time of transmission of a signal either from the clock or from the operator's key over the given length of the line of 3,600 miles, three different methods were devised. One of these was original with Prof. George Davidson, who had charge of the observations. Through the liberality of the management of the Western Union Telegraph Company, a double circuit of line was looped at Cambridge, so that there extended from the San Francisco observatory 3,600 miles to Cambridge, and the return from Cambridge by a somewhat different route of nearly equal length. The two "earths" were under the San Francisco observatory, distant from each other not more than 10ft. The line was first opened by an operator in the observatory, and when the fast connection was made at Cambridge, the San Francisco operator was considerably astonished to get his own message back within one second of time. Then the astronomical break circuit clock was thrown into line, and made its first break on a pen recording upon a revolving cylinder of paper in the San Francisco observatory, and after this break had traversed the line to Cambridge, it returned and made a break upon a second pen moving parallel with the former, in about eight-tenths of a second of time. This was continued every second for several minutes, and was repeated upon several nights, and when one of the twelve batteries in this long circuit was removed the wave length time was reduced to only sixty five hundredths of a second. Communication was, of course, carried on at the same rate of speed. This feat over a line 7,200 miles in length has

been unrivalled up to the present time, both as a practical working exhibit and a scientific success.

Windmills v. Electricity.—The question is one of almost universal interest, why windmills are not more often employed for generating electricity in conjunction with accumulators for storing the energy thus produced. Windmills are not used to such an extent in England as they are in America, but even there windmill generators do not seem to make much progress. Mr. A. R. Woolf, M.E., author of "The Windmill as a Prime Mover," New York, has written a valuable note upon the question of windmills in the *Stevens's Indicator*, in which he says that first credit was due to Sir W. Thomson for suggesting the use of windmills at the meeting of the B.A., 1881, though he expressed doubts as to its utility on account of the comparative cost. Mr. Woolf holds that Sir W. Thomson's reasoning was not quite correct, and that when the only correct basis of comparison of the economy of different prime movers is instituted viz., the cost of obtaining the horse-power developed per unit of time, such cost consisting of the sum of interest, repairs, and depreciation of plant, cost of fuel, oil, and attendance, and similar items of expense entering the power account—the windmill is the most economical motor for the development of power in moderate and small quantities. The non-employment of windmills is not owing to the often alleged fact that the rate of revolution of the windmill, according to the varying force of wind, is too irregular to run a dynamo for the purpose of charging a storage battery, or that the wind cannot be depended on for a sufficient length of time per day. The real facts of the case are that in the leading American windmills as is attested by hundred thousands in daily use in pumping practice—governing appliances of various kinds, of approved design and experience, automatically so vary the extent of surface presented to the wind, that a practically uniform rate of revolution is obtained, irrespective of direction and varying velocities of wind, for all winds exceeding a velocity of six miles per hour. This latter velocity must be reached before windmills of good design, as ordinarily constructed, operate at the rate of revolution for which they are set. It has been found by experience that, on an average, for at least eight hours out of the twenty-four hours of each day, the wind exceeds this velocity of six miles per hour, the average velocity of wind, during the eight hours of run, being 16 miles per hour. Total calms in excess of two days' duration are practically unknown in the United States. The fact that the windmill is at rest, often at short intervals, aggregating not quite sixteen hours out of the twenty-four, is no objection to the use of this motor for the purposes of driving dynamo machines to charge electrical accumulators, for one of the very features and acknowledged requisites of such accumulators should be that they can be charged spasmodically, at will, and at odd times. The result of study of this question must be that the reason windmills are not used in this way, is not that the windmills are not sufficiently economical or reliable, but that the electrical accumulators are not yet a satisfactory and assured success. When they are, windmills will come into extended use as prime movers for the generation of electricity, and electricians will be glad to avail themselves of the most economical motor, utilising the force of wind, otherwise going to waste, for this purpose. The windmill at the present day is in a developed state, a practical success, ready and available for this new use at once. It awaits the electrical accumulator that is a success.

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, D.S.C., F.R.S.E.

[All rights reserved.]

(Continued from page 415.)

TESTS OF LOW RESISTANCE.

Thomson's Secondary Conductor Method.—An excellent method of testing low resistances was proposed about thirty years ago by Sir William Thomson. The arrangement is illustrated diagrammatically in Fig. 20, and a convenient apparatus for carrying out the test practically is illustrated in Fig. 21. From Fig. 20, it will be seen that the arrangement is similar to the ordinary Wheatstone's bridge. The rod, w , to be tested is placed in series with a standard rod, w_1 , and a current is sent through them from the battery, B . The ends of two shunt circuits, containing known resistances, are placed in contact with the rods at the points 1 and 4 and the points 2 and 3, and a galvanometer is joined from 5 to 6. The resistances of these shunt circuits must be so large that the resistance of the contacts at the rods will not produce a sensible percentage change in their value—that is to say, they should be at least a few ohms each. The theory of the method may be stated as follows. Let the difference of potential between the joints 1 and 2, 2 and 5, 5 and 3, &c., be a , b , c , &c. Then we have, when no current flows through the galvanometer, G , the sum of the differences a and b equal to the difference between 1 and 6, or f , and similarly the sum of the differences c and d equal to e . Hence we have

$$a + b = f,$$

and

$$c + d = e.$$

∴

$$a + b = \frac{f}{e} \cdot (c + d)$$

∴

$$c + d = \frac{e}{f} \cdot (a + b)$$

Suppose, now, that $\frac{b}{c}$ is made equal to $\frac{f}{e}$, and we will have

$$\frac{a + b}{c + d} = \frac{b}{c} = \frac{f}{e},$$

and ∴

$$\frac{a}{d} = \frac{b}{c} = \frac{f}{e} \quad \dots \dots \dots (1).$$

Since no current flows through G it is clear that the same current flows from 1 to 6 as flows from 6 to 4, and for the same reason the same current flows through w and w_1 . Hence, if r and r_1 be the resistance from 1 to 2 and from 3 to 4 respectively, and R and R_1 the resistance from 1 to 6 and from 6 to 4 respectively, we have by Ohm's law and equation (1) —

$$\frac{a}{d} = \frac{r}{r_1} \text{ and } \frac{f}{e} = \frac{R}{R_1},$$

and therefore

$$\frac{r}{r_1} = \frac{R}{R_1} \quad \dots \dots \dots (2).$$

Equation (2) shows that the resistance between the points 2 and 3 does not enter into the result explicitly; but it must be remembered that one of the conditions of the solution was that b/c should be equal to f/e , and hence, for absolute accuracy, this condition must be fulfilled. If, however, the sum of the resistances of the parts of the main conductor and the contact at C is small compared with r or r_1 , the difference of potential between 2 and 3 will be small compared with the difference between 1 and 2 or between 3 and 4, and hence a considerable deviation from the proper value of b/c would not introduce much error. It is clear, therefore, that if care be taken to keep the resistance of the primary conductor between 2 and 3 small, the resistance of the secondary conductor between these two points may be made moderately small also, without introducing any serious error due to the resistance of the contacts at 2 and 3. The resistance of the secondary circuit between 1 and 4, however, must always be great compared with the resistance of the contacts at these points. This method possesses considerable advantages in point of sensibility and simplicity. It requires only one galvanometer, and since the method is a zero one any sensitive galvanoscope

will do. The resistances of the secondary conductors may be fixed and unvariable if the points of contact, 1 and 4, can be varied, and therefore the chances of accidental error are small. A convenient form of apparatus for making tests by this method is illustrated in Fig. 21. Referring to this figure, P is a heavy sole plate, on which a vertical board is mounted which supports a double scale rod, D , and two metallic slide rods, A . On the sole plate, and in front of the vertical board, there is fixed a copper block containing two mercury cups, m, m , one at each side of the scale rod. This block serves to connect the standard rod, C , and the rod to be tested, C_1 , and corresponds to the connecting

FIG. 20.

piece, C , in Fig. 20. The tops of the rods, C and C_1 , are fixed in binding screws, t, t , corresponding to the blocks, A and D , in Fig. 20. To the blocks, t, t , the terminals of the battery circuit are to be connected through a reversing key arrangement, as shown. The battery, B , should be capable of producing a considerable current without much polarisation, and the strength of the current should be regulated by resistance placed

FIG. 21.

in its circuit. The reversing key, K , and the galvanometer key, G , may be arranged side by side, and an ordinary lever reversing key used for K , so that the battery and galvanometer circuits may be easily and quickly made and broken during the tests. On the sole plate, P , two resistances, r, r_1 , are fixed, and one end of each of these is attached to a metal strap which carries the terminal, T . These resistances give, when connected to the bottom sliders, S_2, S_3 , the secondary circuit, 2, 5, 3, in Fig. 20. A similar pair of resistances, R, R_1 , are fixed at the top of the vertical board, and when one end of each is attached to a metal strap carrying the terminal T , and the other ends to the upper sliders, S_1, S_4 , they give the secondary circuit, 1, 6, 4, of Fig. 20. The sliders S_1, S_4 consist of a contact piece, c , bevelled

so as to touch the rods, C or C₁, at one edge only, and held against the rod by two springs, s s, which carry insulating pieces on their ends to prevent them touching the rods. The lower sliders are insulated from the slide rods, and the contact tongues, c, are connected directly to the resistances r. The upper sliders are in metallic contact with the slide rods, and the resistances R are connected to them through the slide rods, which are provided with terminals at their upper ends. The slide rods are, of course, so thick that any difference of position of the slider makes no sensible difference in the value of R. The resistances R R and r r are here shown on separate bobbins, but there is some advantage both in cheapness and in efficiency when each pair of them are wound on the same bobbin. The chief advantage in efficiency lies in the fact that the coils, being close together on the same bobbin, their temperatures are always very nearly the same, while the terminals are so close together that there is little chance of much thermo electric disturbance due to difference of temperature at the connections.

To put the test rods in this apparatus, the sliders are turned round in the slide rods as axis, and the test rod placed between the springs, s, and the contact piece, c. The upper end of the rod is then passed through the terminal t until the rod can be turned into position and inserted into the mercury cup, m. The lower contact piece, c, is then set so that its upper edge is in line with the lowest division of the scale, D. The upper slider on the rod, C or C₁, which has the lowest resistance, is then placed so that the lower edge of c is in line with the highest line on the scale, D, and the slider on the other rod moved until no deflection is produced on the galvanometer G when the battery and galvanometer circuits are closed. The proper position for both directions of the current is found and the mean reading taken. When the two resistances R are equal to each other, and also the two resistances r equal to each other, the resistance per unit length of the rod under test, C₁, is to the resistance per unit length of the standard rod, C, in the same ratio as the reading of the top slider on C₁ is to the reading of the top slider on C.

This apparatus is, in the form here shown, most suitable for the measurement of the resistance of a straight rod, and hence its chief use is for the determination of the specific resistance of specimens of thick conductors. It may be readily used, however, for measurement of the resistance of any wire or coil, provided suitable standard rods, C, are available. The wire or coil is substituted for the rod C₁, and, if it consists of flexible wire, it should be provided with stiff terminal pieces for insertion into the sliders S₁ and S₂, the lower terminal piece making contact also with the mercury, cup m. The resistance is then determined by finding the length of the standard rod to which it is equivalent. It is, of course, possible, by using boxes of resistances instead of the fixed resistances r r and R R, to measure the resistance of a coil, although it is considerably greater than that of the standard, by using the proper ratios in the bridge; but it is better to adhere to equal ratios, and provide a sufficient number of standard rods to allow any resistance up to about a tenth of an ohm to be measured. Several other methods of measuring low resistances have been proposed, and some of them, notably a method used by Matthiessen and Hockin in their experiments for the British Association Committee on electrical standards, have been extensively used. The methods here described will, however, be found to be simple, readily applied, and, for almost all purposes, sufficient.

Specific Resistance. The specific resistance of a conductor is the resistance between the ends of the unit length of a specimen of the conductor, the cross section of which is unity. This is clearly equivalent to the resistance of any length of the actual conductor, divided by the length, and multiplied by its cross section. The cross section of the conductor is here supposed to be uniform, or so nearly so that the mean cross section may, without sensible error, be used in the calculation. This is the case with all ordinary wires and rods used in electrical installations. The experimental determination of the specific resistance, s, of any conductor consists therefore in finding, by one or other of the methods above indicated, the resistance, R, of a certain length, l, say

a metre of it; measuring the cross section, a, and then calculating the value from the equation

$$s = R \frac{l}{a}$$

The cross section can generally be determined, especially in the case of thick cylindrical specimens, with sufficient accuracy by direct measurement of the diameter with a micrometer gauge. The diameter should be measured at several points along its length, and also across several diameters for each section. Unless the diameters differ considerably from each other, the mean diameter d may be taken, and the section calculated as

$$a = \frac{\pi d^2}{4}$$

$$\text{or, in this case, } s = \frac{4 R l}{\pi d^2} = \frac{4 R l}{3.1416 d^2}$$

When great accuracy is required, or when the section is irregular, the cross section may be very accurately determined by weighing either the whole specimen, or, if that cannot be readily done, several parts of it, both in air and in water, and calculating the volume from the difference between the two weights. For this purpose it is convenient to take the dimensions in centimetres and the weight in grammes, because, since the weight of a cubic centimetre of water at 4 deg. C. is one gramme, the difference of the weights in grammes gives the volume of water displaced by the specimen—that is to say, the volume of the specimen in cubic centimetres. Thus, let the weight of the specimen in air be w grammes, and the weight in water w₁ grammes. Then its volume, v, is equal to w - w₁ in cubic centimetres, v, w, and w₁ being here treated as simple numbers without reference to the nature of the quantities represented. There are some small corrections required in the simple formula here given when great accuracy is required. In the first place, the weight in air is only accurate when the volume of the body weighed is the same as the volume of the weights used in weighing it, and, again, the density of water changes somewhat rapidly with temperature. Most of the conductors ordinarily used when weighed with brass weights require no sensible correction, for the weight in air and the correction for expansion of water with temperature may be taken as 0.027 per cent. when the water is at 10 deg. C. and 0.10 per cent. when it is at 16 deg. C. Care must be taken, when making the weighing in water, that no air bubbles adhere to the sides of the specimen. This may be very perfectly avoided by putting the specimen in boiling water and allowing it and the water to cool together before weighing, but generally if the specimen be carefully wetted, and weighed at once, almost exactly the true volume will be obtained. The specimen should be weighed in air both before and after it is weighed in the water when it is put in boiling water and allowed to remain in it until the water cools, because in this case it is likely to gain in weight by oxidation. If it is carefully dried first in blotting paper, and then in a current of dry air, so as to avoid oxidation after removal from the water, the weight after removal should be used in the calculation. There should not, however, be such a difference between the weighings as to make any sensible difference in the section of the conductor.

If l₁ be the length of the specimen weighed, w and w₁ the weights in air and water respectively, then

$$a = \frac{w - w_1}{l_1} \text{ and } s = \frac{R l l_1}{w - w_1}$$

With regard to the magnitude of the specimens required for a satisfactory determination of the specific resistance of the material, it may be remarked that a length between the contacts 3 and 4 of Fig. 20, or the corresponding contacts in the other methods, equal to one or more times as many lineal centimetres as there are square centimetres in the cross section, may be measured when proper appliances are available. Care should be taken, however, that the contacts are not made so near the end of the rod that the current is not uniformly distributed across the section. A length equal to two or three times the diameter should always be left between the ends of the rod and the points of contact of the shunt-circuit.

(To be continued.)

ON A NEW COMPOSITE ELECTRIC BALANCE.*

BY SIR WILLIAM THOMSON, F.R.S.

This instrument has been designed for the purpose of providing in one instrument the means of measuring (a) the difference of potential between two points of an electric circuit—as, for instance, the difference of potential between the supply conductors of an electric light installation, (b) the current flowing in such a circuit, and (c) the rate of working in the circuit. The instrument thus forms a combined voltmeter, ampere meter, and watt-meter. The general form of the instrument is similar to that of the standard centi-ampere or deci-ampere current balances, and it consists of (1) two coils of silk covered copper wire fixed one above the other, with their planes horizontal, on a slab of slate; (2), two coils of similar wire made up in the form of anchor rings, and fixed to the ends of a balance beam; (3), two coils fixed similarly to (1), but capable of carrying currents up to 500 amperes. The beam of the balance is suspended by two flat ligaments of fine copper wire in such a position that one of the coils fixed to the ends of the beam is suspended midway between the fixed pair of fine wire coils (1), while the other suspended coil is similarly placed relatively to the thick wire, or current coils. When the instrument is used for the measurement of alternating currents, the strong-current coils are made by two or three turns of a stranded conductor. Each wire of the stranded conductor is covered with silk so as to insulate it from the others, and in order, as far as possible, to annul the effect of induction in causing the current to be different at different distances from the axis of the conductor, the strand is given one turn of twist for each turn round the coil.

The arrangement of the connections in the instrument will be readily understood from the figure, which shows diagrammatically the arrangement of the coils. In this figure, *a* and *b* represent the fixed fine wire coils, *c* and *d* the suspended coils, and *g* and *h* the strong current coils. The instrument is joined in the circuit through a suitable anti-inductive resistance, *R*, through which the current passes to the terminal, *T*, from which the course of the current through the coils to *T*₁ is indicated by the arrows in the diagram; the switch handle, *H*, being in this case turned to "volt." For the measurement of amperes the switch is turned to "watt"—a measured current passed through the suspended coils *c* and *d* of the balance, and the current to be measured passed through the strong-current coils, *g*, *h*, by introducing the electrodes *E*, *E*₁, into the circuit. The current through the suspended coils may sometimes be measured by means of the instrument itself, arranged for the measurement of volts. This may be done by first measuring the current which the difference of potential between the supply conductors of an electrical installation, or between the poles of a battery, causes to flow through the four fine-wire coils of the instrument and its external resistance, and then turning the switch to "watt," and at the same time introducing a resistance into the circuit equal to the resistance of the fixed fine wire coils. When the balance is used as a watt-meter, the switch is turned to "watt," and the terminals, *T*, *T*₁, joined to the supply conductors, while the

* Abstract of a paper read before the Philosophical Society of Glasgow.

current through the main circuit is passed through the coils, *g*, *h*. When the rate of working in an alternate current circuit is measured by such a balance, the anti-inductive resistance, *R*, must be so great that there is no sensible difference of phase between the currents flowing through the fine wire coils of the instrument and the electromotive force on the supply conductors, to which they are connected.

THE MATHER STEAM DYNAMO ELECTRIC MACHINE.

The New York *Electrical Review* gives the following description of a very interesting invention just patented

FIG. 1.—Mather Steam Dynamo.

1 2, field magnets; 3 4, pole pieces; 5 6, bearings; 7, hollow shaft admitting steam; 8, engine shown more fully in Fig. 2; 9 10, armature and ring; 11, commutator; 12, brushes; 13, coil connections; 14 15, binding screws for cable.

by Mr. R. H. Mather, of the Mather Electric Company, which we illustrate herewith, and the invention promises to have a wide field of application. It comprises a dynamo-electric machine, having a Gramme armature, in the interior of which is mounted a suitable type of revolving steam-engine, so that the steam power is applied directly to the armature, instead of being transmitted through belting or connecting shafts. In other words, the driving engine is located entirely within the armature of the dynamo.

FIG. 2.—Steam Engine of the Mather Steam Dynamo.

23 23, steam cylinders; 24 24, pistons; 25, steam-tight casing; 26, valve.

The type of engine selected is that of a three cylinder engine, in which the three pistons receive steam in succession and rotate the armature in a manner which will be readily understood by referring to Fig. 2. The entire engine is contained within a steam-tight metal casing, and on the outside of this casing the armature is mounted.

On account of the necessity of boiler connections and the consequent liability to "grounds," the inventor has introduced an insulating connection in the steam pipe near the dynamo, which entirely insulates the engine and dynamo from the boiler. The steam is taken through the shaft at one end, which is hollow for the purpose, and the exhausted steam is discharged at the other end of the

shaft in a similar manner. The construction is neat, and should be very effective in practice, as it does away with all the lateral thrust of the shaft on its bearings due to the transmission of the power through a belt. The extent of space occupied is inappreciable, as the otherwise waste space inside the armature is utilised for the location of the engine, and this enables the dynamo to be placed in the most confined situations without detriment. We presume the inventor is able to apply a reliable automatic cut-off valve to his special type of engine, so that it will be economical in use under varying loads.

**DIAGRAM SHOWING THE SIZE OF CONDUCTORS
FOR HOUSE WIRING.**

BY C. H. CROCKETT, BOSTON.

In central station systems of incandescent electric lighting, a graphic method for determining the sizes of the

A diagram which will meet all requirements, showing at a glance the correct sizes of wire to use, can be easily constructed for any system of lighting, and can be made of such dimensions as to be carried in the pocket.

All wiremen connected with a central station should be furnished with blue print copies, and the wiring of stores, offices, residences, &c., should be in strict accordance with the values given by these diagrams.

A practical example of such a diagram is here presented. It was designed for 100 volt 75 ampere 16 c.p. lamps for the two or three wire system, with a loss of E.M.F. in the leads of one per cent, one half of this loss to be in the mains and one half to be in the tap or branch wires.

The method of using it is very simple, and is as follows: Follow the vertical line directly under the number representing the total number of lamps to be put in until it meets a horizontal line directly opposite a number corresponding to the average lamp distance of the cut-outs from the service-wires. The nearest curved line to this junction

conductors, for wiring the premises of customers, will be found to be much more convenient than any rule or formula however simple. The chances for mistakes are also less by the use of a graphic method than where repeated mathematical calculations are necessary.

In every healthy and growing central station there are, of course, many of these problems constantly occurring which differ from each other in only two of their factors, namely, the number of lamps to be installed and their distance from a given point. All the factors, such as the E.M.F. required at the lamp terminals, the economy of the lamps used, and the allowable fall of potential in the leads, are constants, the voltage and economy of the lamps depending on the particular system in use, and the drop in the leads being a certain determined percentage of the potential difference at the lamps.

of the vertical and horizontal lines will be marked with the gauge number of the wire to use for the mains.

For a tap or branch wire, determine the number of lamps supplied by such wire and the average distance of these lamps from the cut-out or junction with the mains. Follow the corresponding vertical and horizontal lines on the diagram until they meet, and the nearest curved line will indicate the proper size of wire to use, as was the case with the mains.

As before stated, the diagram is constructed for use with the two or three wire system. For two-wire circuits the upper row of figures for the lamps and the left-hand column of figures for the distances are to be used; for three-wire circuits the lower row and right-hand column are to be used. The following two examples will illustrate the use of the diagram.

1. Required to find the size of conductor necessary to carry 20 16 c.p. lamps of the quality assumed to a distance of 40ft. on the two-wire system.

Answer: Following the vertical line under "20" at the top downward until it meets the horizontal line opposite "40" at the left, they intersect each other near the curve marked "8." Hence No. 8 B.W.G. is the size of conductor required.

2. Required to find the size of conductor necessary to carry 30 lamps 50ft. on the three wire system.

Answer: Following the vertical under "30" in the three wire column until it meets the horizontal opposite "50," also in the three wire column, they intersect near the curve marked "12." Hence No. 12 B.W.G. is the size required.

It will be noticed that the curved lines representing the gauge number of the wires are cut off at their upper ends, stopping under the greatest number of lamps which can be supplied by the different wires without heating. The first curved line met in following down the vertical line under any number of lamps is marked with the gauge number of the smallest wire which can be used for these lamps with safety; how near the limit of safety is approached is also readily seen.

A table of sizes of wire, with their cross-sectional areas and safe current capacity, can be easily combined with the diagram, which will prove a valuable addition. In this particular case the Birmingham wire gauge was adopted. — *New York Electrical World.*

WHY IS ELECTRICITY NOT USED FOR TRAMWAYS?

BY PROF. SIDNEY H. SHORT.

The object of this paper is to examine carefully into the various means of applying electricity as a motive power for street railway traction, and, if possible, to find the answer to the above question.

There are only three systems for the electrical transmission of power, and they are each distinct and complete within themselves, and each relies upon a separate principle and not upon details of construction.

We will take up each of these systems and discuss them upon the data obtained by experiments and actual service, and determine, as near as possible, the actual cost in dollars and cents of operating one car for a day of eighteen hours, from 6 a.m. to 12 p.m.

THE STORAGE BATTERY SYSTEM. Mr. Prescott finds that storage cells give back about 65 per cent. of the electrical energy which they consume. As the average dynamo machine will return about 80 per cent. of the mechanical horse-power of the steam-engine in the form of electrical energy, these cells returned 65 per cent. of 80 per cent., or 52 per cent. of the power delivered by the steam engine.

Now, we may consider the efficiency of the motor to be the same as that of the dynamo, and we have 80 per cent. of 52 per cent., or 41.6 per cent. of the steam engine power delivered up by the motor. The resistance wires used by the storage battery cars for regulation will consume 10 per cent., and the gears 5 per cent. more, and we therefore have 26.6 per cent. of the power of the steam engine delivered to the axles of the car.

At the fourth annual convention of the American Street Railway Association recently held in St. Louis, the committee appointed to investigate the utilisation of electricity for motive purposes reported as follows: "The result of two years working of the electric railroad at Zankerode, Prussia, on the storage battery system, showed that only 30 per cent. of the power of the steam engine was applicable to the propulsion of cars, but even this compares favourably with the cable system." Experience has taught us that, on the average, ten mechanical horse-power must be delivered to the axles of an ordinary loaded standard gauge 16ft. car to provide for its starting quickly after its numerous stops, for running at a speed of eight miles per hour, including stops, and for overcoming the resistance of the track. The efficiency of the storage battery system being but 26.6 per cent., the steam-engine must furnish thirty-eight mechanical horse-power, and the battery 19.7 e.h.p. in order to obtain 10 h.p. at the wheels. As, according to Mr. Prescott, it

requires 126lb. of battery to furnish 1 e.h.p. per hour, it would require 2,482lb. to give the necessary 19.7 e.h.p. per hour, or 14,676lb. over twenty-two tons of battery to be handled for each car every day. Now, it will not do to put more than one ton of accumulator cells on a car in addition to the weight of the motor, and practice proves that it requires twice as long to charge as to discharge the cells, hence it would require three sets of cells, each set weighing one ton, to operate each car. Then, in order to furnish the power represented by the twenty-two tons, these sets must each be used seven or eight times a day, making a change of battery necessary for each car every forty nine minutes. This is about the length of time a pair of horses are used on roads with heavy traffic.

On an average city railway system, where the line is ten miles long, and operates twenty cars, it would require, with the storage battery system, a steam plant of 800 h.p. working up to its capacity all the time, and sixty tons of accumulator cells. These cells would require changing fourteen times in every eighteen hours, making 420 changes, of two tons each, during the day. This would require two sets of men twenty in each set. On this basis I find the cost of operating each car for eighteen horses to be \$8.92, exclusive of driver, conductor, management, interest, and repairs.

THE PARALLEL SYSTEM. We now come to consider the future outlook of the electrical railway as depending upon the system at present mostly used, that is, furnishing a constant pressure upon conductors which are supported above the track throughout the entire length, or placed in a conduit between the rails.

The current is sometimes made to pass out from a constant pressure dynamo along a single conductor above the track, through the motor, and then returned by the rails of the track to the dynamo. This, however, is exceedingly dangerous, and in no case should be permitted, as life has already been destroyed by such construction. When a second wire is added, as described above, the two run parallel with each other the entire length of the line, the current goes out on one wire, passes through a motor, and back by the other wire to the generator. If a second car is to be operated, two paths are made across from one wire to the other, and it takes twice as much current from the generator to run the two cars as it did the one; with three cars three times the current; with four cars four times the quantity, till finally the current becomes so large in quantity that conductors of any practical size will be unable to carry it without growing very hot. The parallel system works under the following disadvantages —

1. The well known law that the power lost on a conductor is proportional to the square of the current on that conductor, so if it costs one dollar per day to send current enough over a given conductor to run one car, to run two cars, twice the current must go over this conductor, which will cost not two, but four dollars, for three cars it would cost nine dollars, five, twenty five dollars, and for ten cars it would cost one hundred dollars to force sufficient current over these wires to drive the cars. This refers only to the loss on the conductors.

2. A system of this kind is subject to a complete stoppage of traffic at any moment, by a wire falling across the two parallel conductors. In the meantime, the generator at the driving station would have its armature burned, or break its driving belt.

3. Upon this parallel system if a car were completely stalled, which is a common occurrence with street cars, either from an overload, being derailed, or having the brakes set, and the current were then turned full into the motor, it would be destroyed by having its coils burned out.

4. In this system the motors have a large amount of power at or near the driving station, but the power falls as the distance from the station increases. Cars should have the same power throughout the entire length of the circuit, in order to allow them to run faster towards the outskirts of the city, and make up their time.

5. Each motor on a parallel circuit depends for its power and speed upon the movements of the rest of the motors on that circuit, making it vary in speed, and require constant attention from the car driver.

6. The regulation of the motors, operated on these

parallel circuits, is accomplished by means of resistance coils being thrown into and out of the circuit. As it always requires power to send a current through a resistance, these coils are, from their very nature, intended to be power dissipators, and, therefore, consume coal without returning any useful equivalent. They are unscientific contrivances, and cannot be permitted in any perfect system of electrical distribution of power. In addition, these resistance coils are dangerous, as they become very hot, and have often set fire to the woodwork of the cars.

7. On all these parallel circuits a dynamo is used, which keeps up a pressure between the wires all the time, even when the circuit is broken. Any person coming in contact with these wires would sustain severe injuries, and possibly it would result in death if the pressure reached much over 400 volts.

Taking the same data used with the storage battery system *i.e.*, 10 miles of track, 20 cars, speed 8 miles per hour including stops, 16 ft. cars, loaded, 18 hours a day, 10 h.p. delivered to the wheels, efficiency of dynamo and motors 80 per cent, using copper wire $\frac{1}{2}$ in. in diameter, and a pressure of 400 volts between the terminals of the motors. I find the cost of operating each car for 18 hours to be 12.12 dollars, exclusive of management, drivers, conductors, repairs, and interest on investment.

THE SERIES SYSTEM.—A new method for propelling street cars has been developed through the application of the old, time-tried principle of driving an electric current through a number of electrical receptive devices and operating them all in succession before the current is allowed to return to the generator. This principle has been used for the past fifty years in the electric telegraph, where the current from a small battery is passed over a single wire and through all the instruments on the line in succession; and who would think of operating a telegraph line upon any other system? The operation of these telegraph instruments is simply electrical transmission of power on a small scale. For the past fifteen years the wonderful success of the arc system of electric lighting, where one current is made to pass through each lamp on the circuit in succession, has again demonstrated the practicability of the series method of transmission of power, and the fact that arc electric lighting has been such a financial success proves the economy of this method.

Why should we not apply this same principle to the transmission of power for driving street cars?

The advantages of this method of propelling street cars are as follows:—

1. In the series system of transmitting power, a simple, constant current is used, which does not vary in quantity no matter how many cars are operated upon the circuit; therefore, the power required to drive that current over a given conductor remains the same under all conditions of operation. If it costs \$1.00 a day to send sufficient current over a conductor to run one car, it will cost the same for two, three, five, or any number of cars.*

2. Should a wire fall across the conductor in this system of electrical railway, the traffic would not be interfered with, as the cars would move on as before, and the generator at the driving station know nothing of the existence of such a "cross."

3. Upon this series system, should a car for any reason be completely stalled, no harm would be done to the motor.

4. In this system the motors have as much power at the most distant point from the station as at the station itself, for the same current passes throughout the entire line.

5. Each motor on a series circuit is independent for its power and speed of all the other motors. A car once set for a certain speed will continue to run at that speed until changed.

6. The regulation of the motors operated on the series circuit is accomplished by simply rotating the brushes around the commutator, no resistance coils or switches being introduced into the circuit to consume coal uselessly or set fire to the car.

7. Plain series-wound generators are used to operate

* This statement is manifestly wrong. The author seems to forget that larger engines and dynamos would be required to give the greater E.M.F. necessary to send a current through a series of motors than through a single one. Ed. E. E.

motors in series, and should the wires break from any cause the dynamo would immediately go out of action, and no electric pressure would exist on the wire, which could be handled without the slightest shock. The pressure at the terminals of these series motors can easily be kept below 300 volts, therefore, would be harmless to either man or beast.

Still, using the same data as with the storage system, I find the cost of operating each car for eighteen hours to be \$2.22, exclusive of driver, conductor, management, repairs, and interest on investment.

Benjamin F. Thomas, Professor of Physics at the Ohio State University, in an article in the *Ohio State Journal*, March 22nd, 1888, referring to the first road constructed on this new system, writes as follows: "Two cars were run, each carrying a load of pig iron equal in weight to about one hundred passengers. They were run at various speeds, stopped and started on grades, and put to as severe a trial as could possibly arise in regular use. The cars were under perfect control, and were run up a part of the track rising three feet in one hundred, at a speed of thirteen miles per hour. The mechanical devices used on the line are simple and positive in action, and if a line should be built in the substantial manner proposed by Prof. Short, I see no reason why it should not operate regularly and satisfactorily. A speed of ten miles an hour with full loads, and including stops, can easily be made."—*Street Railway Journal*.

PROSPECTS IN AMERICA.

The great and continual increase of electric lighting in America, in comparison with the comparatively quiet state of the industry in England, often leads young electrical engineers to look with some longing to a land whose scope is so vast and where new plants are so constantly being installed, and not a few English electrical engineers have found pastures new on the other side of the water. But a word of warning is certainly necessary for anyone contemplating such a step. Many young men have saved or obtained sufficient to reach the other side, and with little spare money, but great hopes and several letters of introduction to those in authority, have wandered forth to make their fortunes. On arrival they have found, to their dismay, that places in the east were not to be had; the great electric installations were hundreds, or even thousands, of miles across the mainland west; and they have found, moreover, a very distinctive feature of American society that their letters of introduction, an "Open Sesame" of great potency in this country, have little or no importance in the land of freedom, where any man considers himself at liberty to call abruptly upon another, and where employers take practically little or no notice of mere friendly introductions. An introduction from the highest would carry little or no weight, competence being the great voucher. A certificate of proficiency from a college or from a well-known electrician would, of course, carry weight, but influence as known in England is practically missing. A certificate also of mere book proficiency will serve nothing. The electrician there must know how to handle his tools quickly and skilfully, must be sharp in business capacity, and have a sufficient stock of ready money to tide him over the first few months of waiting and enquiry, and to carry him, may be, a long journey across west. Many of the most successful electricians of America have come from England, and "Britishers" are always appreciated; but any young electrical engineer intending to go across should first wisely realise the conditions which will confront him.

M. de Wroblewsky.—The death, consequent upon an accident in the laboratory, of this Austrian scientist is announced as having taken place at Cracow. His name will be associated with the study of phenomena occurring at low temperature; and amongst these the continuous diminution with temperature of the electrical resistance of copper is not the least interesting.

THE ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at **THREE WORDS for ONE PENNY**, with a **MINIMUM** charge of **SIXPENCE**.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.		6 months.		12 months.	
United Kingdom	3s.	3d.	6s.	6d.	13s.	0d.
Within the Postal Union	4s.	4d.	8s.	8d.	17s.	4d.
Other Places.....	4s.	10d.	8s.	8d.	19s.	6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

GOING FOR THE TECHNICAL PRESS.

The humorous badinage of Mr. Preece at the expense of the technical papers last week at the Society of Telegraph-Engineers, in conjunction with other remarks made at the same time and place, are rather rousing incentives to a retort courteous. Leader writing should be abandoned, because, forsooth, if nobody reads the leaders in the *Times*, ergo nobody reads the leaders in the technical papers. Such is the argument à la Preece. We are to restrict ourselves to facts, and never give opinions under penalty of excommunication, though some unreasoning creatures will urge that facts give rise to opinions, which frequently lead to experiments, and thus on to more facts. The time has hardly come yet when we may venture to write upon the tomb of Progress, *Requiescat in pace*. Really, life is too long to be able to deal with nothing but facts. Further, all letters over a *nom-de-plume* are to be tabooed. They are tabooed in some countries, so much so that the ephemeral technical literature hardly ever contains anything in the shape of a letter. If correspondence is always to be signed, then should articles; and though one should talk boastfully about the courage of his opinions, there are times and circumstances and opinions held which, if the criticisms were to be put into writing over a true name signature, would cause all the courage to ooze out with the perspiration at the fingers' ends. Of course if nothing could be written but undeniable, undisputable facts, the matter would be different; but even Mr. Preece expresses the opinion that there should be but "one set of fire rules." Surely the poor downtrodden scribe may venture with trembling fingers to follow so good an example.

Taking a considerable leap as regards Mr. Preece's remarks, we should like to consider for a moment the enormous question raised at the conclusion of his paper as to the education of the future Electrical Engineer. We will arrogate to ourselves a position and a knowledge that Mr. Preece refuses the technical papers, and say that the necessary education must come, and can come only, by the aid of the technical press. Mr. Preece's opinion as to the valuelessness of the technical papers weighs as nothing when compared with the facts of the case. His education, the education of every man who holds a position in the world, is obtained in two ways—by experience, and from current literature. School books are mostly written or compiled by men who know nothing practically of the subject upon which they write, and the more pretentious and costly books, however carefully written, and however rapidly edition follows edition, are generally months, if not years, out of date. The books that are far ahead of the time are few in number, and are almost wholly connected with pure science. Men do not read current

literature as they should do. We know that the strong meat is therein usually diluted with an abundance of verbosity, that makes one who is really abreast of the times frequently cry out, Words, words, nothing but words. Practical men, as a rule, have no talent for condensation; they meander along painfully and verbosely, but the kernel is there, and the learner has to find it, or stand back. Experience is gained to the extent of at least 95 per cent. by reading current literature. The chemist does not need the experience of the girl who, to clean out a glycerine bottle, poured in a little nitric acid, and followed the doctoral formula, "to be well shaken before taken." Experience does not necessarily mean trying an experiment yourself, or seeing it tried. Experience in some instances may be gained from a speech or from a paper just as well, if not better, than in the laboratory or the workshop. It has been the custom in England to ridicule the technical press. It is the downtrodden worm that never turns. The Lord Mayor never makes merry with its members at the Mansion House, nor does a Prime Minister ever condescend to acknowledge its existence by the gift of medals and decorations—putty or otherwise. It is tolerated, not loved, in most businesses—despised if it happens to express any opinion contrary to the notions of the reader, flattered if anything is to be gained thereby, kicked with impunity because its traditions are totally against such low and hurtful occupations as duelling. The technical press can afford to make merry over the criticisms against it, inasmuch as no one will take these adverse knocks seriously, but as in reality directed against one or two offenders, through whose offences the whole "in a loomp is bad," as Tennyson has it.

There is still one other matter against which we feel inclined to rebel—viz, to the statement that the responsible authorities of the technical papers—still "in the loomp"—did not make sufficient efforts to obtain information first-hand as regards the "fire rules" and the negotiations between the committee and Mr. Heaply. We do not think the criticism was intended to extend further, and even so far the accusation was too sweeping. We can at any rate speak to the fact that at least one paper knew the position of both parties at first-hand, and Mr. Preece's expressed wish over and over again reiterated during the reading of his paper, was but a modification of the last sentence of our note of April 13 as follows: "We regret that some way has not been found to bring the conflicting interests into agreement." We refrained from commenting upon the "society's rules," or in any way expressing opinions that might further tend to widen the breach, hoping that the multiplication of office rules would intensify the feeling among the best contractors that ten—or two—sets of rules are bad, and that sufficient influence would be brought to bear upon the offices to bring them

into accord. The tendency of the paper and the discussion which followed was to bring about the consummation of this happy state of things, and we trust the further discussion will bring about a final settlement pleasing to all parties concerned.

REPORT UPON JARMAN'S ELECTRIC TRAMCAR.

Elsewhere we insert a report of an experimental run of this tramcar. A purpose is to be served by this report, in that, whether it be considered from the scientific or the commercial standpoint, it is altogether faulty. On the one hand, it errs in saying what might be well left unsaid; on the other, it leaves unsaid what ought to be said. Whether it is right for us to state facts and ignore opinions, is a question of some importance when matters of this kind are under consideration. One section of the reading public, having little knowledge of technical matters, looks to the technical press for guidance. The advice given, it is true, is seldom followed, but that arises more from the inherent tendency of the Englishman to gamble, rather than from the conviction that the investment is safe. Reports of the kind we notice are obtained only with the ulterior object either to get money upon patents, or to promote a company. The investing public may be influenced by sentences judiciously chosen from any report, but when a report is given in full a considerable advantage arises, as the whole is taken to be favourable. To the initiated the report we give elsewhere is absolutely colourless. From it no one can gain the information required to compare cost, either initially or of maintenance. The first part merely details the arrangement of the machinery and gearing. We then have certain figures, from which it is stated "it is evident that at least three such double journeys may be performed without recharging the accumulators." Now we are prepared to stake our reputation upon the fact that the figures tell you nothing of the kind, nor does anything in the report lead to the proof that "there would be a distinct saving per car-mile over the present cost of maintaining a number of horses to perform the same work." We accept all the facts and figures given, but they tell us nothing. With regard to the use of two motors, that, perhaps, may be a matter of opinion, but in our opinion one only is required. Gearing neither complicated nor costly can be fitted so as to drive in either direction with the motor running constantly in one direction. A cabman does not take out two horses to work his cab for fear one should break down. Yet horses do break down, as do machines. A motor is a machine, but we no more expect it to break down at its ordinary work than we do a locomotive, and the sooner the insane idea about duplicating everything electrical is knocked on the head the better. Messrs. Immisch will gladly supply any number of motors,

and will guarantee these motors to run as well as any other class of machinery without breaking down.

The figures we want should show the actual cost, all things considered, per mile run. We require to know a good deal more about weights than can be found in this report. Far more information is given in Prof. Short's paper, though even this must be read *cum grano salis*, because the author is professedly the advocate of a particular system.

THOMSON'S ELECTRIC METER.

For the purpose of obtaining a meter which shall register the amount of current, either continuous or alternating, passing through a circuit, Prof. Elihu Thomson has recently constructed an ingenious form of meter, in which the heating property of the current is employed as a means of effecting motion in a registering train. The accompanying illustration shows one form of the apparatus designed by

Prof. Elihu Thomson's Meter.

Prof. Thomson. It consists essentially of two bulbs, B B', attached to each other by a tube, T, of narrow bore, or so arranged as to resist the rapid flow of liquid through it. Two small resistances, K K', are sealed into the bulbs, which are partly filled with alcohol, which is boiled, and the whole is sealed when the alcohol vapour has completely filled the interior space.

At the top of the central pillar is a knife edge support which carries the frame, F P, to which the bulbs and tube are attached. The suspension is so arranged that the centre of gravity is above the point of support, so that the arrangement is in unstable equilibrium. Thus it cannot rest in a middle position, but tips either way, according to the excess of weight on either side. Mercury cups, C C' and C' C', receive alternately the ends of the wires leading to the coils, K K', in accordance with the position of the bulbs, so that when B is down the coil K is in circuit, and the coil K' out of circuit, and vice versa. While the wires dipping into the cups, C C', may be arranged so as to make contact just before the others in C' C' break their contact, this need not be the condition, for, by interposing a resistance, R, as a bridge, the circuit is maintained, even though a break should occur between C C' and C' C'. The operation of the apparatus will now be readily understood. Assuming the bulb B to be depressed, so that its heating coil K is in circuit, if a certain number of lamps, L, be fed by a current, the coil K will be fed by a definite proportion of it, and will cause a slight warming of it in the

liquid in the bulb B. This will result in depressing the level of the liquid in the bulb, due to increased vapour tension and a resisted flow of the liquid through the tube, T, into the bulb B'. This action continues until the accumulated weight in the bulb B is sufficient to tip the apparatus over and connect the coil K' instead of the coil K in circuit. The reverse action now takes place, resulting in a depression of the level in the bulb B, and an elevation of that in bulb B', until an overbalance is reached, when the arm is again tilted, and so on. At each complete oscillation the pawl, P, moves the register and counts a definite amount of current consumed.

EFFECT OF CHLORINE ON THE ELECTROMOTIVE FORCE OF A VOLTAIC COUPLE.*

BY DR. G. GORR, F.R.S.

If the electromotive force of a small voltaic couple of unamalgamated magnesium and platinum in distilled water is balanced through the coil of a moderately sensitive galvanometer of about 100 ohms resistance, by means of that of a small Daniell's cell plus that of a sufficient number of couples of iron and german silver of a suitable thermoelectric pile (see *Proc. Birmingham Philos. Soc.*, Vol. iv., p. 130), the degree of potential being noted, and sufficiently minute quantities of very dilute chlorine water are then added in succession to the distilled water, the degree of electromotive force of the couple is not affected until a certain definite proportion of chlorine has been added, the potential then suddenly commences to increase, and continues to do so with each further addition within a certain limit. Instead of making the experiment by adding chlorine water, it may be made by gradually diluting a very weak aqueous solution of chlorine.

The minimum proportion of chlorine necessary to cause this sudden change of electromotive force is extremely small; in my experiments it has been one part in 17,000 million parts of water, or less than one 7,000th part of that required to yield a barely perceptible sparsity in ten times the bulk of a solution of sal ammoniac by means of nitrate of silver. The quantity of liquid required for acting upon the couple is small, and it would be easy to detect the effect of the above proportion or of less than one 10,000 millionth part of a grain of chlorine in one tenth of a cubic centimetre of distilled water by this process. The same kind of action occurs with other electrolytes, but requires larger proportions of dissolved substance.

As the degree of sensitiveness of the method appears extreme, I add the following remarks. The original solution of washed chlorine in distilled water was prepared in a dark place by the usual method from hydrochloric acid and manganic oxide, and was kept in an opaque well-stoppered bottle in the dark. The strength of this liquid was found by means of volumetric analysis with a standard solution of argentic nitrate in the usual manner, the accuracy of the silver solution being proved by means of a known weight of pure chloride of sodium. The chlorine liquid contained 2.3 milligrammes, or .03565 grains of chlorine, per cubic centimetre, and was just about three-fourths saturated.

One-tenth of a cubic centimetre of this solution ("No. 1"), or .003565 grains of chlorine, was added to 9.9 c.c. of distilled water and mixed. One cubic centimetre of this second liquid ("No. 2"), or .0003565 grains of chlorine, was added to 99 c.c. of water and mixed; the resulting liquid ("No. 3") contained .00003565 grains of chlorine per cubic centimetre. To make the solutions ("No. 4") for exciting the voltaic couple, successive portions of 1 10th or 1 20th c.c. of "No. 3" liquid were added to 990 cubic centimetres of distilled water and mixed.

I have employed the foregoing method for examining the states and degrees of combination of dissolved substances in electrolytes, and am also investigating its various relations.

* Read before the Royal Society, May 3, 1888.

+ As one part of chlorine in 17,612 million parts of water had no visible effect, and in 17,000 millions had a least perceptible effect, the minimum of the difference, or of one part in 500,000 millions, has been determined.

ELECTRIC LIGHTING.

Proposed conditions of contract under which electric light wires may be laid in the streets of Paris :

Continued from page 451.

CHAPTER III*Responsibility.*

ART. 23.—The licensee shall be responsible to the town and to any other party for any damage consequent upon the installation, the presence, or the working of electrical conductors.

Moreover, the licensee renounces any right of taking proceedings against the town of Paris in consequence of damage occurring to his system of conductors or installations, by reason of accidents due to work carried out on the public way or to any other cause. He preserves his right of proceeding against any other party, but declares that he renounces the right of taking proceedings against the town of Paris.

Security.

ART. 21. As a guarantee that the above mentioned obligations will be duly conformed to, the licensee is to deposit as security at the municipal counting house a sum of

The security is to consist of French funds, or bonds of the town of Paris, at the mean rate prevalent on the day prior to the deposit. The interest thereon will be drawn by the licensee.

Fines.

ART. 25. Any neglect of the clauses in the conditions of contract, or any infringement of the rules in force or the directions laid down by the Administration within the limits of the rights conferred upon it by the conditions of contract, will incur the application of a fine of 50fr. for each infringement, and for each day until the execution of the directions, without its being necessary to proceed in due form of law and without prejudice to the application of the clauses relative to the withdrawal of the authorisation.

The amount of these fines, as well as legal expenses, will be deducted from the amount deposited as security, which amount must be reconstituted at its original value within the maximum period of one month after the said deduction.

In case of insufficiency or of non-reconstitution of the security, the administration shall have the right to seize the working plant of the licensee until payment be duly made.

These provisions are equally applicable in case the licensee shall not pay over at the municipal counting house, within the stated period, the dues to be paid by him to the town in virtue of the present conditions of contract.

Proportion of Foreign Workmen and Conditions of Work.

ART. 26. The proportion of foreign workmen employed by the licensee shall not exceed one tenth of the whole.

The working day shall be of nine hours.

The working hour of the electrical and mechanical workman shall be paid at the minimum wage of 0fr. 80 centimes from 6 in the morning to 6 at night, 1fr. 20 centimes from 6 p.m. to midnight, 1fr. 60 centimes from midnight to 6 a.m.

These minimum prices shall be revised every five years, and shall vary in the same proportion as the mean salaries entered on the list of the town of Paris. For work that may be specified in these lists the wages shall be in accordance with the said lists.

French Materials.

ART. 27. All the materials employed shall be of French manufacture.

Authorisation to be obtained outside of the Municipal Administration.

ART. 28. The licensee will be bound to obtain, in due course, any further authorisations which may be necessary outside of the Municipal Administration of Paris.

Election of Residence.

The licensee shall preferably have registered offices in Paris. In case he should not do so, any notification or

information addressed to him at the office of the secretary of the Prefecture of the Seine shall be valid.

Expenses of Stamps and Registration, Taxes, Contributions, &c.

ART. 30. The cost of stamping, registering, printing, and all other costs consequent upon the present authorisation shall be met by the licensee.

The same applies to all taxes and contributions, of whatever nature they may be, which may arise in consequence of the present authorisation.

The present conditions of contract are drawn up by the Director of Public Roads and Promenades.

ELECTRICITY FOR INCREASING THE TRACTIVE ADHESION OF LOCOMOTIVES AND MOTOR CARS.

The Commissioner of Patents, on March 21, granted to Messrs. Elias E. Ries and Albert H. Henderson, of Baltimore, Md., three patents on methods and apparatus for increasing the tractive power of locomotives and other self-propelled railway vehicles by electricity, which promise to be of very considerable importance both from a scientific and practical standpoint.

These patents cover broadly the use of an electric current for increasing the frictional adhesion between the driving wheels and rails, and the patentees have found that by this means the tractive power of locomotives and self-propelled motor cars can be nearly doubled without any increase in their weight, and also that no retardation is offered to the motive power by reason of the traction.

This system claims to make railroading practicable in spite of storms of snow and sleet, and surmounts as well as other difficulties that steam and street railways now have to contend with.

This increased traction is due to a temporary molecular change in the metal at the points of contact between the driving wheels and the track rails, caused by the passage from one to the other of a "transformed" electric current of large volume and small electromotive force or pressure.

The current is generated, according to one of these patents, by a small dynamo electric machine carried by the locomotive, from which, after being passed through an electrical converter, it is made to pass through, and traverse in succession, all of the driving wheels and that part of the track rails lying between them, which latter serve to complete the circuit as the locomotive or motor car moves along. The amount of increased traction thus obtainable is described as being very great, and can be regulated to suit the requirements by means of a simple switch that controls the flow of current through the "traction circuit."

An important peculiarity of this invention is that the tractive adhesion is not affected by snow or ice on the tracks, since the normal heat of the transformed current produced at the point of contact can be increased sufficiently to instantly vaporise any moisture that adheres to the surface of the rails, thereby clearing the rails as fast as the locomotive or motor car passes over the road.

In experiments recently made by Messrs. Ries and Henderson, before several of the U.S. Patent Office Examiners, the fact that the passage of the electric current increased the tractive effects in the manner claimed by them was thoroughly demonstrated, and a small railway car, equipped with the device, ascended and descended without the least difficulty a grade of 40 per cent., or 2,088ft. to the mile, whereas a 7 per cent. grade in practice can be surmounted only with the greatest difficulty under the most favourable circumstance by ordinarily equipped locomotives.

The apparatus is very ingenious, and has the appearance of the greatest simplicity. If all the claims made for the system are realised in practice, there can be no doubt but that it will work a revolution in railway operation, produce as fully as great a change in the manipulation and safety of steam railways as did the adoption of the air brake, and supply the missing link to a successful operation of street cars by electricity.

By its means, the inventors claim, it becomes possible to ascend the steepest grades under all conditions of snow

weather with perfect safety; slipping of the wheels upon the rails, especially noticeable in wet weather, and the consequent loss of time now resulting from this cause will be entirely avoided: faster speed can be attained, and trains can be started and stopped within less time than is at present occupied, because of the increased grip of the wheels when starting, and the prevention of what is termed as "skidding" when the breaks are applied; and last, but not least, a locomotive or motor car can, without any increase in its weight, draw nearly twice the load it is at present capable of moving, and thus, it is claimed, at less cost than, and without the wear and tear occasioned by, the sand now ineffectually used for this purpose by railroad companies.

Owing to the extremely low tension of the currents of electricity employed in this system, there is absolutely no danger of shock or escape of current, and only that portion of the rails lying immediately below the locomotive is charged by the traction circuit. This method of increasing tractive adhesion formed the subject of an elaborate paper read by Mr. Elias E. Ries before the American Association for the Advancement of Science, at their last annual meeting (see Sci. Am. Supplement for Dec. 10, 1887), and elicited a great deal of favourable comment at the time, in view of the novelty and importance of the principle involved.—*American Engineer.*

JARMAN'S ELECTRIC TRAMCAR.

We have received a report by Messrs. Fredk. Walker and Hyde on Jarman's Electric Tramcar, which reads as follows:—

"In accordance with instructions received, we conducted an experimental test of the efficiency of Mr. Jarman's system of electrical traction during a trial run from Clapham to Westminster Bridge and back on the 10th inst.

"The whole of the locomotive machinery is arranged beneath the floor of the car, and comprises two series electric motors, both armatures of which are mounted upon one spindle, a wrought-iron pinion of twelve teeth being keyed centrally upon said spindle, the motion being thus transmitted to an intermediate shaft, the motor pinion gears with a mortice wheel of 48 teeth, and a second pinion of 24 teeth also keyed upon the intermediate shaft, gears with a similar mortice wheel of 48 teeth keyed upon the driving axle of the tramcar. The peculiarity of the gearing lies in the fact that the mortice wheels above referred to are geared with cogs formed of vulcanised fibre, and flanges are extended up to the top of the tooth, the whole being secured by pins passing through the width of each cog at the pitch line, and which are riveted over through the flanges. The motors are arranged so that while one is propelling the car in one direction, the armature of the other is rotating freely within the corresponding field, thereby allowing of the free circulation of air for cooling. In this way one motor may be used for the outward journey, and its armature may be cooled, while the other motor is performing the return journey. If additional power be required, both motors may be used at once. The reversal and control of the two motors is effected from either end of the car by means of levers acting upon double sets of brushes, and the regulating switch is also duplicated, so that the car can be driven from either end. An ingenious press contact enables the driver to operate an electric gong with his knee, and a lever brake, acting upon the high speed shaft, effectually checks the car, and brings it to rest immediately. The instruments used in taking readings for the following table were an Ayton and Perry ampere meter and voltmeter, both of which were accurately calibrated and checked for the occasion.

OUTWARD JOURNEY.

Time of starting from Clapham	12.48 a.m.
" arrival at Westminster	1.10 a.m.
Average speed, miles per hour	8.43 miles.
Current at starting on level road	47 amperes.
Mean current during journey	25.5 amperes.
Mean E.M.F.	147 volts.

RETURN JOURNEY.

Time of starting from Westminster Bridge	1.35 a.m.
" arrival at Clapham	2.7 a.m.
Average speed, miles per hour, deducting two stoppages	7.83 miles.
Current at starting on a gradient of 1 in 20	69 amperes.
Mean current during journey	26.4 amperes.
Mean E.M.F.	142 volts.
Average u.b.p.	5.01 e.h.p.

Both armatures were perfectly cool.

"From the foregoing figures it is evident that at least three such double journeys may be performed without recharging the accumulators, allowing a fair margin for extra weight, bad state of track, weather, &c.

"The accumulators being arranged in trays, mounted upon wheels, and placed under the seats, may be run out through doors at each end upon a suitable track or platform upon the arrival of the car at the

charging depot, and in our opinion the operation of taking out the discharged cells and replacing them by others newly charged, could be performed by two men in five minutes.

"There were 23 persons upon the car, the general structure of which is much heavier than the modern cars of the same rating now being used upon the Metropolitan lines and we consider that the whole system has been well designed and carried out in a practical and efficient manner, and if a charging installation for even two or more cars was laid down, there would be a distinct saving per car mile over the present cost of maintaining a number of horses to perform the same work, and that the system could be worked even on a small scale efficiently and profitably."

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—May 10.

The President, Mr. E. GRAVES, in the chair.

The paper was by Mr. W. H. Preece, F.R.S., Past President, on "The Risks of Fire incidental to Electric Lighting."

This paper seemed to be one more especially directed to put the position of the society in its connection with fire rules clearly and fully before the members and the public, rather than to consider any scientific questions involved in protecting buildings from fire risks due to their being lighted by electricity. No man could possibly be better put forward with this object in view than the author of the paper, who, though he managed to say a few pretty straight things all round, also bestowed almost as universally a modicum of praise. The one direction in which Mr. Preece hit out unsparingly was at the technical press. [The cap does not fit us, and we decline to put it on. If Mr. Preece wishes to hit out straight at us, he has only to say so, and we are quite ready to defend every action we have taken with regard to fire rules. It is not quite just to condemn indiscriminately when one particular culprit is aimed at.]

Mr. Preece commenced by explaining at some length the action of the society in appointing a committee, the constitution of that committee, the difficulties in the way of working a large committee, the negotiations with Mr. Heaphy, and the break between the committee and Mr. Heaphy. The sum and substance of all this comes to the fact that a difference of opinion exists, or did exist, between the committee and Mr. Heaphy. The former contend that the work of the committee consists in tabulating a number of general principles—abstract principles, if you like—not rules to be adopted by a fire office. The working rules must, they say, be special—framed, it is true, in accordance with these abstract principles, but nothing more. The one does not interfere the slightest with the other. The society deals with "pure science," leaving the fire offices to apply as they see fit, but contending all along that if the application agrees not with these principles, the offices will go wrong. Such, we gathered, was the argument of Mr. Preece. But the paper was not wholly devoted to the committee v. Heaphy. The author went on to indicate the necessity of following rules. He pointed out that we had scares where no danger existed, or could exist—as at Lord Brassey's; that, however, some disastrous fires have been traced to electric lighting. Very ably, succinctly, and clearly, he laid bare the dangerous spots in light installations. Gutta-percha and indiarubber had their uses, and for certain purposes were almost perfect, but not in electric lighting. Ammoniacal emanations from stables endangered the wiring and insulation. Ordinary cleansing operations found out danger spots; rats and mice were enemies to be greatly feared. Mercury was on no account to be used, though very handy, sooner or later the user had to pay the penalty. The worst of all plague spots were bad joints, bad connections, switches, and cut-outs. At this part of the paper there was some very plain speaking about bad workmanship—jerry installation work, as it might well be called. The technical papers, too, were damned as giving opinions and not facts, as attributing to greenhorns and to a happy-go-lucky committee statements which had been discussed by the most experienced members of the profession. [We could agree with Mr. Preece if he corrected his grammar—put the singular and not the plural, "a technical paper," not "the technical papers."] The author also stated that none of the technical papers attempted to get correct information—did not go to Mr. Preece or to the

committee. [Here, again, Mr. Preece is led astray in making a sweeping condemnation instead of a restricted one.]

With almost every other remark we cordially agree. Mr. Preece was in accord with most electrical engineers when he pronounced against more than "one set of rules." He contended, also, than for the first time in the history of electrical science a line of demarcation had been drawn by the committee, dividing high and low tension. Rule 32, he said, was the defining rule, which practically states that from henceforth all E.M.F.s over 200 give high tension currents, all under give low tension. In conclusion, the author summed up the precautions to be taken to prevent accidents. We are to have proper design, proper construction, and proper inspection. Preferably, like Mr. Gordon, no joints at all, but if they must be, then be careful to have the best joints possible. Good workmanship should reign supreme, and under these conditions, and using a good insulator that was unflammable, most of the dangers existing likely to create fires would cease, and the millennium of electric lighting would dawn. To get this happy state it is necessary to duly educate the coming race of electrical engineers.

In the discussion which followed the paper, Messrs. Heaphy, Hedges, Swan, J. Verity, Manville, Crompton, Siemens, and others took part, but for all practical purposes the remarks were directed against a multiplication of fire office rules, and it was more than once hinted that a way might be found whereby all existing differences would vanish. The meeting adjourned for a week, when Mr. Heaphy promised to fully state his view of the case.

Subsequently Mr. Preece exhibited a new insulator, which he thinks meets the wants of electric light engineers, and of which we shall have more to say in another issue.

STUDENTS' MEETING—May 8, 1888.

Mr. W. M. Mordey occupied the chair.

Mr. E. J. Rynoe read a paper on "Electric Welding," describing the methods used by Prof. Elihu Thomson and by M. Benardos, the latter more in detail, the author having visited the works of M. Benardos at St. Petersburg, and having also seen his experiments at Paris. He had obtained many specimens, many of which he exhibited at the meeting. From his experience he stated in many joints exhibited by M. Benardos appeared perfect outwardly, but when carefully examined the weld proved simply superficial.

Mr. Mordey said the paper, although a record of failures, was not less interesting or useful on that account. He thought that many of the failures made by persons who had experimented with electric welding were probably due to the fact that they were not sufficiently acquainted with ordinary welding, in which, perhaps, they would not have been much more successful. The amount of power used by M. Benardos was out of all proportion to the effect sought, and on this score the process of Prof. Elihu Thomson had a decided advantage. A probable application of the latter method would be in heating and soldering—not welding—conductors for street mains. He knew of no other means by which such an operation could be readily carried out. By this method it was possible to heat up a joint very quickly and to localise the heat.

Mr. Hume drew attention to the fact that electric welding had been used some three or four years ago by Messrs. Siemens for connecting rails at the Ryde Pier.

After some remarks from Messrs. Marsh and Hayne, Mr. Rynoe replied.

Specimens of Thomson's electric welds were kindly lent by Prof. Forbes, to whom the thanks of the meeting are due.

A vote of thanks to the chairman concluded the meeting.

PHYSICAL SOCIETY—May 12.

Prof. REINOLD, F.R.S. (President), in the chair.

Mr G. L. Addenbrooke and Mr. H. A. Cunyngnam were elected members of the society. The following papers were then read.

"Note on the Condition of Self-Excitation in a Dynamo Machine," by Prof. S. P. THOMPSON, D.Sc.

It is a well known fact that a series dynamo running at a given speed will not excite itself unless the resistance is less than a certain value depending on the speed and construction of the machine, and if the resistance is slightly less than this critical value the excitation will not be such as to saturate the magnets. According to the primitive statement of the action of self-exciting dynamos on the "compound interest law," a dynamo should excite itself to saturation at any finite speed providing the resistance is not infinite. An explanation of the observed facts is given

in the paper without any assumption as the curve of magnetisation. If $E = \text{E.M.F. of the machine}$, $n = \text{speed}$, $C = \text{number of wires on outside of armature}$, $N = \text{number of magnetic lines}$, $i = \text{current}$, $S = \text{number of turns on magnet}$, ΣR , and ΣS the sums of the electric and magnetic resistances respectively, then $E = n C N$, $i = n C N \Sigma R$, and $N = 4 \pi S \Sigma S$. From these it is easily seen that $4 \pi n C S = \Sigma S \cdot \Sigma R (A)$ —i.e., for a dynamo running at constant speed, the product of the magnetic and electric resistances is constant, and the dynamo will not excite itself if ΣR is greater than $4 \pi n C S \Sigma S$. Similarly, for a given value of ΣR , excitation is impossible if n is less than $\Sigma S \cdot \Sigma R / 4 \pi C S$. For a value of ΣR , less than the critical value, the excitation increases until the magnetic resistance is increased, so that equation (A) is satisfied. The corresponding formula for shunt machines is $4 \pi n C Z = \Sigma S \left\{ (r_a r_s) + \frac{r_s r_e}{R} \right\}$,

where $Z = \text{number of shunt turns}$, r_a , r_s , and R , the resistances of armature, shunt, and external circuits respectively. In the discussion which followed, Mr. Kapp described a method used in testing dynamos for determining the minimum speed at which the dynamos will excite themselves, and from thence determining the magnetic resistance of the air gap. In all cases, experiment showed this to be less than the calculated resistance, generally in the proportion of 1,500 to 1,860, the difference being greater in low tension machines. Prof. Ayrton pointed out that permanent magnetism was not taken into account, and that the apparent resistance, due to self-induction, and between the brushes and commutator were considerable for small currents.

Lord Rayleigh said Sir W. Thomson had shown critical speeds for given resistances to exist in Faraday's disc dynamo. He (Lord Rayleigh) did not approve of the term "magnetic resistance," and thought "reluctance," as recently suggested by Mr. Heaviside, would be preferable.

"On Magnetic Lag and the work lost due to Magnetic Lag in Alternating Current Transformers," by Mr. THOMAS H. BLAKESLEY, M.A.

The method adopted to detect the lag is to place dynamometers in both circuits, and one with a coil in each. Then, on the supposition that the E.M.F. of the secondary circuit is entirely due to the changing magnetism of the core, the author proves that the tangent of the magnetic lag angle must be equal to

$$\frac{\frac{m}{n} C a_2 - B a_1}{\frac{m}{n} \sqrt{(A B_1 a_1 a_2 - C^2 a_2^2)}}$$

where m and n are the numbers of turns in the primary and secondary coils respectively; A , B , C , the constants of the dynamometers, and a_1 , a_2 , a_3 , their angular readings,

A is such that $A a_1 = \frac{I_1^2}{2}$ where I_1 is the maximum value of the primary current. A table of actual results is given, where the magnetic lag is about $5\frac{1}{2}\%$. The whole power given out by the machine takes the form $r_1 A a_1 + r_2 \frac{m}{n} C a_3$

where r_1 and r_2 are the resistances of the primary and secondary circuits, while the power lost in hysteresis is expressed by $r_2 \left(\frac{m}{n} C a_1 - B a_2 \right)$. The lag is attributed to an induced magnetic stress called into being by the increasing or decreasing magnetism itself, and always opposing it, as motion in a medium induces an opposing force of friction. By supposing such an induced magnetic stress in quadrature (as Mr. Blakesley expresses it) with the magnetism, and of such a value as, when compounded with the stresses due to the currents, shall bring the resultant into quadrature with the secondary current, the effective magnetic stress is obtained. This involves a new idea, called magnetic self induction, with its coefficient. The whole problem is treated by the geometrical method which the author has applied to several other problems in alternating currents.

Mr. Kapp, Prof. Thompson, Perry, and Ayrton, and Lord Rayleigh took part in discussing the paper.

"Note on the Conditions of Self-Regulation in a Constant Potential Dynamo Machine," by Prof. S. P. THOMSON, D.Sc.

In "Dynamo Electric Machinery" a formula $\frac{Z}{S} = \frac{r_s}{r_a r_m}$ is given as expressing the ratio of the numbers of turns in the shunt and series windings of a compound dynamo. This is on the assumption that there is no saturation within the working limits. As this assumption is not legitimate, a correcting factor is necessary. The factor is shown to be the ratio of the average permeability over the whole working range, to the permeability corresponding with no external current. The formula is transformed so as to be expressed in terms of the "saturation" data of the machine, which, as shown in a previous paper, can be calculated from its details.

"On a Simple Apparatus for the Measurement of the Coefficient of Expansion by Heat," by Prof. W. E. AYRTON, F.R.S. and Prof. J. PERRY F.R.S.

The apparatus consists of a metal tube, within which the wire or rod, whose coefficient is to be determined, is placed. One end of the wire is rigidly attached to one end of the tube, and the other end connected to an Ayrton and Perry magnifying spring, a pointer attached to which indicates the change of length due to alteration of temperature. Steam or water may be passed through the tube, the temperature of the wire being shown on a thermometer. The arrangement is very sensitive, and with a pointer about 20 c.m. long the motion is magnified about 1,000 times. A magnifying spring attached to an aneroid was also shown, and its great sensibility demonstrated. A combination of a spring of large diameter and pitch with one of small diameter and pitch was exhibited. By such a combination small rotations can be immensely magnified. The great features of the patent spring as a magnifier are the entire absence of friction and back lash, and the large range of proportionality.

A "Note on the Governors of Electromotors," by the same authors, and one on the "Electrical Action of Light," by Prof. W. E. Ayrton, were postponed until next meeting.

FACETIÆ.

Motto for a church: "Spare the rod and spoil the church."

The resistance of the human body, according to J. L. Sullivan, is very small, but has increased lately.

DEATH BY CABLE. A Kansas correspondent says it is significant that there is a morgue at the foot of the cable tramway inclines in that enterprising city.

THE LATEST FROM AMERICA. "Natural electricity" (?) has been discovered in America, in a disused pump well, and the pipe has become a permanent magnet—parts of the pump and pieces of steel adhering to it.

ANOTHER FLAID. A man who fell to the ground in the street in New York, last week, was supposed to have received a shock from an electric light wire. It was subsequently learned that it was not "electric fluid," but an altogether different variety, which caused his steps to totter.

ELECTRICITY IN THE HAIR DYEING BUSINESS. An overseer in one of the American mills has been taking shock from one of the large belts which is in rapid motion near his head, and his fine head of iron-grey hair has changed to a beautiful bay. No doubt, says the *New York Electrical Review*, the belts being leather, some of the tan colouring matter has been transplanted, electrically, into the hair, and gone into the dyeing business.

Kiel. Messrs. Brennan and Company are establishing a central station for distributing electrical power for arc and incandescence lighting at the works of the Imperial torpedo depot at Friedrichsort, near Kiel.

ELECTRIC LIGHTING FROM CENTRAL STATIONS.*

BY R. E. B. CROMPTON.

The object of this paper is to put before you, the Society of Arts, some public data on which you can form your own opinions on the vexed question whether the electric light will soon be generally distributed as a means of lighting our houses. Although we see electric lighting extending on all sides in large establishments, many of you think that for some time to come it is likely to remain a luxury reserved for the rich. I hope, however, to show you that this need not necessarily be so, and that one very potent means of furthering its wider introduction is by making generally known the causes which are now retarding it. As all of you know, our private houses can only be lighted on an extended scale from central stations, and I wish to call your attention to the various points in which this central station lighting differs from the detached installations, which are now so well understood that they no longer present features of special interest. The plant for producing the electric light may be divided into generating and distributing apparatus. In a detached installation the whole system of engines and dynamos generating the electricity, as well as conductors distributing it to the lamps, is self-contained, generally within one building. At any rate, the system of conductors which connect the generating station with the lamps does not extend beyond the property of the consumer, but in the case of central station lighting the electricity is generated at a station placed more or less central to the area to be supplied, and from thence the conductors are taken through the public streets to be lighted, and it is this difficulty of dealing with the system of conducting mains which has so long retarded the investment of capital in systems of supply from central stations.

Lord Crawford and Mr. Ferranti, and others working with him, have within the last two years distributed electricity, by means of overhead wires, from a central station close to the Grosvenor Gallery. They have been able to do this because at the present moment no one has any control over the fixing of overhead wires. It is only necessary to obtain the consent of the householders of the roofs upon which it is proposed to place the supporting posts. Such a system of distribution has answered extremely well, so long as central stations have had to pick their customers far and wide, but the case will be very different when all the houses, or the greater part of them, take the light. When this is the case, it will be absolutely necessary to put the conductors underground. I myself am engineer to a company, which is successfully working a central station at Kensington, for supply to the houses around Kensington Gore and Knightsbridge, and in this case I have commenced by putting all my conductors underground, and have experienced not a few of the difficulties which I am about to describe.

As I believe the after-all cost of electric lighting will be the chief factor in determining its future extension, I think it best to commence by showing you that the main body of householders can only afford to spend a certain sum on their lighting, so that, if the electric light cannot be supplied for this sum, its use will be restricted. The usual laws of demand and supply will hold good when applied to the sale of electricity, as to any other commodity; that is to say, for equal profits the price can be reduced as the extent of the sale augments. But we must start with a sum which a householder can now afford to pay, and I think I can show you that, light for light, this sum may be considerably higher than that now paid for gas. Let us see what this amounts to. A Londoner who is tenant or owner of a house having three reception-rooms, ten bedrooms, and the usual offices and passages—in all, having about fifty burners fixed in them spends about £25 a year for his lighting. His gas bill will be about £15; lamp, oil, candles, and matches, about £10; and his average coal bill will be about £25. But this £50 does not nearly represent the total cost of his lighting and heating. Repairs, renewals, cleaning of the house and furniture, inseparably connected with the lighting and heating, form a large item—in fact, a larger item than any body would imagine who had not added them up and averaged them over a term of years. Although a great deal has been made of the damage done to ceilings, hangings, the bindings of books—in fact, everything fixed in the upper part of our rooms—by the fumes and smoke of burning gas, few people consider what a large share of the labour of our household servants is connected with cleaning grates, carrying coals, and the dusting of furniture, caused by the use of coal, how greatly the wear and tear of our carpets is increased by droppings from candles, by hot cinders falling from the grates, and by perpetual lifting to make way for the chimney-sweep, and by carrying coals up and down stairs.

A large proportion of the small repair bills we pay are in connection with the kitchen and other grates, hot water boilers, gas fittings, candlesticks, lamps, and oil, and the like. In fact, it is not too much to say that if we deduct the one important item of the repair of the exterior and the roof of the house itself, four-fifths of the remainder of our annual repair bills are

* Paper read at the Society of Arts, Wednesday, May 16.

spent in connection with lighting and heating. And it is quite certain that if electric light was introduced into such houses, and the bulk of heating and cooking done by gas, that this heavy annual bill would be considerably reduced, probably by £30 or £40 at least. Our householder could then well afford to pay £25 for his electric light, £20 for the increased quantity of gas he would use for heating, and, as English people will always insist upon an open grate in the drawing room, £5 for wood fuel for this drawing room fire. His pocket would then be the gainer of the £30 or £40 that he would save on repairs. We thus see our way for an income for the electric light company, providing that they can light a house for £25 a year, and this without ousting the gas company. The seller of house coals would no doubt suffer to some extent, but he would be partially compensated by selling steam coal to the electric light companies. Although this picture of the lion lying down with the lamb (i.e., the gas company with the electric light company) seems almost to utopian to be realised, I think it deserves your most careful study and attention, for in its partial realisation we may have some hope of fighting the smoke and fog demon which overshadows our beloved London. And I assure you that if you, the householders, will play your part, by encouraging the use of gas cooking and heating, and by taking up electricity for lighting, we, the electric light people, will play ours and will supply the electricity.

I have above mentioned the sum of £25 a year as one that could be paid by a householder owning or tenant of a house of the size I have taken as representing the average, having 50 electric lights fixed. At present it has been found that supply companies cannot charge much less than 8d. per Board of Trade unit for electricity. Now £25 a year means a trifle over two units a day, and this is equal to only 31 lamp-hours if the large 20 candle-power lamps are used throughout, but experience has shown us at Kensington that the most lamp to use is one of about 10 to 11 candles, taking 53 watts. The two units per day will be sufficient for 62 such lamp-hours, and practice has shown that this average daily supply is amply sufficient for the brilliant lighting of such a house as I have described, if due care has been taken in the placing of the lights, and arrangements are made to switch off the lights in such rooms and passages in which light is not constantly required. As with gas, so with electricity; the burners that make up the bill are those that are constantly burning, such as lamps in the hall, in the various passages, staircases, &c. But there is no need for those who wish to be economical to burn electric lamps constantly in places corresponding to those it is necessary to keep gas constantly burning. The reasons being obvious, it is not worth while to frequently turn out the gas, and then be at the trouble of getting matches and relighting it each time a person goes backward and forward, whereas the handling of an electric-light switch is quite another matter. I have recently devised means by which the whole series of lights, from the entrance right up to the passages at the top of a house, can be turned on simultaneously from any part, either from the entrance or from the first floor, or from the top of the house, so that anyone coming home late and finding his home in darkness can light up the whole of the passages by one switch as he enters, and put the whole out again as he goes into his bedroom. By such devices as these, great saving can be effected in the quantity of electricity used, as the saving made in the current used by these constant burning lamps allows for a corresponding increase of lighting in the dwelling and bedrooms at other times. It is manifestly against the interests of the electric light that it should always be associated with an extravagant display of light. Where much light is given it must necessarily be expensive, and others are consequently deterred from adopting electricity. The best customers a lighting company can have are those who use their lights to the best possible advantage. It is far better for a lighting company to have to supply current to a large number of economical customers than to a smaller number of less thrifty ones. Another method by which the cost of the electric light may be greatly reduced to the householder is by the increased use of portable fittings, such as table standard lamps, removable brackets, and such like. Setting on one side the not inconsiderable saving to the householder of the cost of the fittings themselves, the mere fact that such fittings are used, considerably reduces the maximum number that can be intentionally or accidentally turned on at one time, and thus greatly reduces the size of the generating plant required to supply this maximum. Further than this, the smaller unit of light placed in a table is, of course, more efficient than lamps hung from the ceiling. Having shown you that you can have your electricity, and can afford to pay for it, I want you to understand the difficulties which beset the electrical engineer, who has to provide the system of distributing mains from the generating station to your houses. As I have before said, in this portion of the undertaking lies the whole of our difficulties. The regulation of these mains has been made the subject of an Act of Parliament, which has undoubtedly been one cause of retarding electric lighting in this country; at any rate, it is difficult for anyone who has not himself been engaged

in the work to realise the long and wearisome delays, and the obstructions thrown in the way of electric light companies striving to obtain the requisite permission to lay these conductors.

As I have shown above, we do not wish to be rivals of the gas companies; we wish to live alongside of them. We believe there is room for both of us, but still comparisons will be made, and it is only fair to say that the conditions under which we at present labour are not equally fair to gas and to electricity. The gas companies have certain well-defined powers and well-defined obligations. There has been no attempt to apply to them the doctrine, that all undertakings for public supply must have but a limited tenure only, and become the property of the public authority after certain fixed periods. It has been said over and over again that never more will such powers be given in perpetuity as are now given to the gas companies, but still every year parliamentary sanction is given to the new undertakings under the Gas Acts, which grant these very self-same perpetual powers. No one appears to have brought forward the absolute unfairness of this course, but as long as this difference exists, it is manifestly a logical sequence that, as capital which will be employed by electric light companies will not have the same security of tenure as that employed by gas companies, the former will have to pay dearer for it. This feeling that the electric light companies are to pay ransom in some form or other has got so strongly into the minds of the various local authorities, whose permission must be first obtained before conductors can be laid in the streets, that it is at the present moment a very potent cause of delaying the introduction of the light. I have never been able to understand why clear-headed men of business sitting on our London vestries, when they set themselves to consider the applications of the electric light companies to lay conductors, appear to forget the most obvious principles which govern supply and demand. No doubt their dislike to the present commanding position obtained by the gas companies is their reason for the caution. They appear to think that unless they tie the electric light companies hand and foot the gas monopoly will be repeated, forgetting that, although the gas companies at present have the monopoly of lighting, the mere fact of the wide introduction of electricity would destroy this monopoly, and by introducing competition accomplish the very thing that they desire. Still more incomprehensible is the wish of some of these bodies to become themselves the suppliers of the electric light. Surely the enterprise is not in such an advanced state that sufficient data have been accumulated to show that public moneys may be safely invested in systems of electric supply. How can any member of a vestry or local board imagine that his board would be allowed to raise money on the security of the rates for the purpose of supplying electricity to only a part of the ratepayers; but such, nevertheless, is the case. Many members do think so, and the operations of the electric light supply companies who are seeking permission to lay their mains are delayed accordingly. There is no need for local authorities to be thus chary in granting permissions to respectable companies, for they have ample means of protecting the interests of their ratepayers from a dear and inefficient supply of electricity. They are not able, even if they wish it, to grant any monopoly to any one lighting company to lay down their conductors in the streets, so that in the event of the first company abusing the powers given to it, either by charging too high prices or by not supplying a regular and constant service, they can correct the matter by allowing a second company to compete. An efficient service of electrical supply is very easy to define. As long as the E.M.F. or electrical pressure is kept constant, and there is no break of continuity in the supply, nothing further need be asked for, as electricity, not being a material substance, cannot be adulterated, or, as Sir Frederick Bramwell once put it very happily, there is no need to define how many grains of sulphur is allowable in an ampere of electricity. In addition to the long and wearying delay of obtaining the consent of some of our local authorities (and it must be remembered that London is so split up, that it is very difficult to obtain a district which does not trench on ground of more than one vestry, so that the final consent of several vestries must be obtained before the work can be proceeded with in any portion of the district intended to be lighted), there are several other delays in the shape of permissions to be obtained from the Board of Trade and from the Postmaster-General. On the whole, it may be said that, as the law now stands, it takes nearly a year to obtain all the permissions that are necessary before the contractor who is to lay the conductors can break ground; and it is obvious that if you, the English public, are really anxious for the light and intend to have it, you have it in your power to direct your vestrymen to be less obstructive. After all permissions have been obtained, an entirely new series of troubles are met with. Anyone of you who have seen a trench open in a London footway must have noticed the large number of small service pipes which cross the footway at right angles. These pipes are at all depths, some of them close to the surface of the ground, some of them very much deeper. In most cases the footways pass over collar arches. It will be seen

that there is very little space between the crowns of these arches and the under-side of the flags or the surface of the asphalt. But this small space is all that is available in which to lay the electric conductors, and our troubles in arranging to get them into it are not small. I should much like to use the French word "canalisation" for the whole system of conductors which convey the electricity from the central station right up to the lamps. We have no equivalent English term, the nearest expression that I can use is to call the "canalisation" the system of conducting mains. These conducting mains, the material they should be made of, and the best method of laying them, form the most difficult point that the electrical engineer has now to deal with. It is the one part of the plant which is hardly at all employed on private installations, even if these are of large size; consequently, we English engineers have had small experience to enable us to determine the best material to use and the best methods of laying. In America, where the progress of central stations has been so very great, in most cases overhead wires have been used, fixed to posts in the street, and which I do not think would be allowed at all in England, and certainly not in London. Nor is any great extension of the present system of overhead wires, such as you use radiating from the Grosvenor Gallery, likely to be allowed. We therefore have to devote all our energies to the best, cheapest, and most durable methods of laying our conductors underground, and, as far as possible, in the footways.

The various modes of laying the conductors may be divided into two classes. 1. By insulated cables, with the appearance of which you are all familiar, laid either in troughs, drawn into pipes, or into bitumen cases, or (2) by bare copper conductors, stretched on earthenware or glass insulators, in culverts, or small subways, formed just beneath the surface of the footway. One or other of the first methods are most commonly employed. But during the last year I have laid down in Kensington considerable lengths of bare copper conductor in culverts, as above described, with most satisfactory results. The completed conductor consists of such durable materials, and the facilities for repairs and renewals, and for exchanging or increasing the size of the conductor itself, are so great, that it is particularly suited for electric lighting at its present stage, when we are very uncertain as to the number of houses that each conductor will have to supply during the next few years. Our case is very different from that of the gas companies, who lay down their mains with the full knowledge that every house fronted by the mains will have to take the gas to a larger or smaller extent. We, on the contrary, having to compete with the existing supply, in most cases do not know what proportion of the houses will take the current. It is a great point, therefore, to be able to lay down a small conductor in the first instance, and be able to increase it by adding copper at a later date, and any system we employ must fulfil this requirement. If it were not for the many transverse pipes above mentioned, the culvert system I have described would best fulfil all the requirements, but unless these pipes can be all got below the culvert, or grouped so as to cross the culvert at regular intervals in masses of solid brickwork, it would not be safe to use the bare copper conductors, for when these stretch they might come in contact with these pipes, and so make an earth connection. For such places we have to effect a compromise, by using short lengths of insulated cable drawn into pipes or bitumen cases. However, we must also so arrange matters that we can alter, repair, or renew the cables without again breaking up the surface of the footway, and this we must do by having surface boxes with removable covers at frequent intervals through which access can be given to the culverts or to the pipes containing the conductors.

The probability that for some years to come we shall not supply the current to a considerable percentage of the houses fronted by the mains, makes it at present necessary to estimate for a great length of conducting mains in proportion to the houses supplied. After careful consideration, I have come to the conclusion that in London we cannot calculate on requiring less than twenty yards of main conductor laid for every house supplied—that is to say, for 1,000 houses we should require 20,000 yards of conductors; and as the cost of taking up and replacing the surface of an asphalt footway is about 11s. a yard, you will see that this item comes to more than £5 of capital charge for every house supplied. A great point would be gained if it were rendered obligatory on the gas and water companies to place their service pipes at a greater depth below the surface than they are at present, and this could be very easily arranged. If this could be done in all cases, so that culverts measuring eight or nine inches in the clear could be provided, it would make the laying and care of our conductors comparatively plain sailing, and would save enormous sums of money to the lighting company, and hence would react favourably on the cost of the light itself.

About half of the capital required for a central station supply system is required for the conductors themselves; so that I do not think that I have dwelt at too great length on this portion of the subject. Hitherto it has been the weak spot in all estimates, both for capital and maintenance, that we have been able

to lay before intending investors; but the uncertainties, both as to first cost and cost of maintenance, are rapidly being removed, on account of the data we are obtaining from works recently carried out. We may now discuss the question of electric light supply companies as an investment for capital. I think no one will deny that enough has been done to show that electric light can be produced at a certain cost in detached installations, and I have shown above that the only unknown factor which introduces an element of uncertainty in the cost of production by central stations is the one of first cost and maintenance of conductors, but even if we charge the cost of production with the highest figures for cost of maintenance of conductors that are reasonably possible, we have ample grounds for showing that capital invested in electric supply will be highly remunerative so soon as the demand for lighting becomes general. Adopting the figures before given, viz., 8d. per unit, and estimating that the income from each house taking the light will average about £25 a year, I have made calculations that the company will cover its expenses and begin to pay dividends as soon as the number of houses taking the light exceeds 20 per cent of the whole number fronting the mains. Roughly speaking, the capital required for plant of every description may be taken at £50 to £60 each house supplied. I think it is likely there will soon be a revolution of feeling in favour of this class of investment. No doubt for some years we have been feeling the over-speculation in electric light shares which took place in 1881 and the years immediately following, when companies were promoted for the sole purpose of selling electric patents. The case now is widely different. As I have just said, the bulk of the money required will or ought to be spent in providing plant, of which half will be the cost of the conducting mains. I use the word ought, because at present the Parliamentary and other costs connected with obtaining permissions, to which I have called your attention, are very heavy, and I cannot help thinking that the greater part of it is unnecessary. One of the great enemies to the progress of central station lighting has been the wild promises that have been made by inventors of various forms of primary batteries, who are telling you every day that they will light your houses with some form of primary battery that can be put in your cellar, and which will require no attention. I have been over and over again told by my friends that they intend to have nothing to do with the electric light until they can get it in some simple form of this kind, and that they feel convinced that they will get it. The sooner the conviction is brought home to them that anything of the kind is absolutely hopeless, and that the large amount of electrical energy required for lighting your houses cannot by any possibility whatever be generated in the space available in a cellar, the better it will be for electric light prospects. I make this assertion confidently, as I know I have the whole body of electrical engineers at my back. I do not call inventors of primary batteries, or promoters of companies connected with them, electrical engineers in any sense of the word. They are in most cases self-deceivers who believe in their own promises, but they do not understand the most rudimentary laws of the conservation of energy or of the value of commercial products. One favourite bait they offer to an intending investor or intending user is, that he will be able to sell the waste products of his battery at a higher price than he gave for the materials originally put into it. They do not seem to see that the obvious question that everybody must at once put to them is—Why do not, then, chemical manufacturers at once adopt these batteries as the means of manufacturing this self-same product? But it is useless wasting words on this subject. I only wish to point out to you that every man who puts off the lighting of his house in the hope that some day some wonderful invention or improvement will be produced in the form of a primary battery is an enemy to the progress of the electric light. The capital for electric lighting must always, to a large extent, be invested in generating machinery and in distribution by means of conductors. In these conductors little or no progress is likely to be made further than in the direction I have indicated of an improved system of culverts to carry them. We know the generating machinery has already reached a high degree of perfection. Every day we hear of sets of steam engines and dynamos returning the shape of electricity 75 and 82 per cent of the energy put into the cylinder of the steam-engine. Having already obtained such high efficiencies, we can hope for very small advantages to the consumer from further improvements in either generating or distributing plant. Doubtless great improvements will be made in the manufacture of the incandescent lamps we use. They may be made vastly more efficient, but every man using the electric light will be able to avail himself continuously of the improvements of the lamp by putting them in as his old ones wear out; so there is no reason why he should put off taking the light on this account. I have shown you that it will pay the householders handsomely to take the electric light now at the comparatively high price we must charge so long as only a small percentage of the houses take the light. Prices can be reduced and profits augmented simultaneously. The consumer will get the benefit of reduced prices, and the investor simultaneously will get

better profits as every man persuades his neighbour to take the light. We are told that the cost of wiring houses, and the fact that we have not yet got a trustworthy meter, are two formidable objects to the spread of electricity. It is quite true that no man likes to be called upon to spend £100 in putting in the wires and electric fittings in a house in which he has already spent a considerable sum on gas-fitting. The electric companies would no doubt be willing to furnish the wires and fittings on the deferred payment system; but, unfortunately, in the present state of the law they would be unable to retain any property in the wires and fittings during the time that the instalments remain unpaid. So that, in default of payment, they would not be able to take them back again, as the wiring and greater part of the fittings would remain fixtures, and the property of the landlord. It is possible that a clause might be introduced in the Electric Lighting Bill now before Parliament, putting electric light fittings into a different category to ordinary landlords' fixtures. At present, no householder who is near the end of a lease is likely to take up the electric light; and this matter obviously requires remedy. In conclusion, I have gone as rapidly as possible over the various matters which are affecting the introduction of the electric light into your houses. I have endeavoured, as far as possible, to adhere strictly to the subject of the paper, although in many cases sorely tempted to describe to you the various improvements and novelties that have taken place in connection with this most interesting subject. If, however, I have succeeded in bringing home to you what a powerful factor in the success of electric lighting is the intelligent co-operation of the public themselves who want the light, I shall feel that I have succeeded in my object.

So far I have kept this paper as little technical as possible, and have said nothing about the best system of distribution to be employed, or on the vexed question of transformers *versus* accumulators. I myself have recently read a paper at the Society of Telegraph Engineers on this subject, and placed before that society the results of my investigations on the capital and maintenance cost of lighting a district of London by the two methods of alternating currents using transformers, and direct currents using accumulators. The general results arrived at, however, are before you in the tables which you see on the wall. Table 3 shows that the cost of generating and distributing plant, carried out on either of the above systems, will cost about £60,000 for plant sufficient for 1,000 houses of the size I have throughout spoken of. Table 4 shows that the working expenses of producing the electricity for these 1,000 houses would vary from £8,600 to £12,000, according to the system adopted the gross income in both cases being £25,000. This paper has been hotly discussed, but entirely from the point of view that all my prices both for capital charges and for maintenance were fixed too high. Without taking advantage of this opinion, the above figures give at length the data on which I have based the statement I have before made, that the question of electric light supply companies becoming dividend-paying concerns, depends almost entirely on the number of houses joined on to the mains. As the tables, which are based on the supposition that two houses out of every three fronting the mains will take the light, show that capital invested in plant ought to earn a dividend of at least 10 or 12 per cent after putting aside sufficient reserve fund to meet depreciation and all such charges. The other two tables, Nos. 1 and 2, show you the cost of having 100 yards of double conductor underground the footway of a London street—Table 1 by means of insulated conductors drawn into bitumen casings, and these figures will hold good if iron pipes or wood troughing filled in with bitumen are employed. Table 2 shows the cost of having similar conductors in bare copper strip insulated by porcelain insulators in the culverts. You will see that whereas in Table 1 the price per lb of copper laid complete varies from 4s. 1d. down to 2s. 6d. for heavy conductors according as the section is increased, in Table 2 the cost for equal sizes varies from 3s. 6d. down to about 1s. In both cases you will notice what an important part the cost of taking up and replacing the pavement bears to the whole cost of laying the conductors.

(For Tables, see *Electrical Engineer*, April 13, p. 343.)

DISCUSSION.

Col. Innes, after complimenting Mr. Crompton on his paper, said that coming from America he felt like coming from light into darkness. Few people here, he thought, had any true idea how general the electric light was in America; the trains in passing along at night seem to be in continual twilight from the distant light from the towns. He had been informed on good authority that there was no town in America of over 10,000 inhabitants that was not lighted by electricity. With regard to primary batteries, he thought Mr. Crompton ought not to say that success would never attend the use of primary batteries. Mr. Crompton could not possibly know all the laws of Nature, and he thought that people had some good right in looking forward to a great development in the production of electricity by chemical means.

General Webber said he was greatly interested in the way Mr. Crompton had discussed the question from a different point of view from that taken at the Society of Telegraph Engineers. One of the things which had struck him throughout the whole controversy, was that

when gas was first introduced—he did not remember it himself, but had often heard of the question from Dr. Letheby—that great difficulty was experienced in getting a proper holder for the gas, and trouble often arose from supplying the gas direct from the retorts. No doubt this difficulty had been shortly overcome; still it was some considerable time before a good gas-holder was produced—a far longer time than it has taken to get a good holder for use in electric lighting. Subject to certain improvement in manufacture of large quantities, which we may now expect, we have in the accumulator a safe, reliable, and efficient store of electrical energy. As to overhead cables, they might be seen even now in London crossing and recrossing the streets in a very objectionable fashion, and he was certain that such a system on an extended scale could not be a permanent one.

Mr. Bromhead asked whether the fittings could not be made movable so as to belong to the tenants themselves, and not to the landlords. He suggested that Mr. Crompton was too sanguine as to the use of gas in heating, which was very expensive for this purpose. Hot water and steam, as used on the Continent and in America, were far less expensive than gas. In America, the absence of gas works in new towns was no doubt one great cause, but the great secret of success was the use of water power, which he would advocate in England.

Mr. Mordey wished to point out that out of 100 central stations in America, many paying good dividends, not one used accumulators. Accumulators had their place, in mansions or where a few lamps were required all night; but on the merits of accumulators the electrical engineers, as a body, were at least divided. In the case of temporary high loads, there was no need to run the whole of the machinery ready to supply the greatest quantity. American companies were quite content to earn their dividends with direct driving plants. He would like to say a word as to underground cables. Many persons object to them for the reason that good insulation could not be kept at high potential underground. He would mention, as an interesting case, that of the City lighting, the current for which the Brush Company supplied for some years from Lambeth. The cable was an early one, poorly insulated with gutta-percha and drawn through iron pipes, and the joints were not well made. Electricians would, no doubt, be surprised when he told them that the insulation resistance of this cable was often not greater than the copper resistance, yet it was found possible to keep a high-tension current in continual use in the cable. It was evident, from this fact, that electricians would not find much difficulty now in distributing high-tension currents in underground mains.

Mr. Swinburne advocated the use of gas heating, and with regard to the spread of electric lighting in London, said that few people had any idea of how much it had already spread. Half a million incandescent lamps were being sold a year for use in London alone, which showed, he thought, we were not so backward as some would have us imagine.

Mr. Addenbrooke said that too much was made of the unsightliness of overhead electric wires. He had a considerable experience in this respect, and as a rule it was then endeavour to get a row of poles along both sides of the street, in many cases as far back on the roof that the wires could not be seen, and crossing only at one end. It must be remembered, too, that electricity was forced to seek its customers; they had to persuade people to give up gas for electricity. An overhead wire could be easily taken to some considerable distance to a customer, around which centre other customers might soon come. If necessary afterwards, underground mains might be laid, but at present he thought overhead wires would lead to the greater development of the lighting.

A Householder said that the most important question of all was the certainty of the electric light, and he would like to ask Mr. Crompton on that point. He had been at St. James's Hall when the whole lighting went out, and on Christmas Eve many shops lost much of their custom through the Grosvenor supply suddenly failing.

Mr. Crompton, in reply, said that as to the question of primary batteries, he had the whole of the electrical engineers at his back. Gentlemen who believed that we were within measurable distance of an immense development in the shape of chemical production of electricity were, he thought, imperfectly educated. The whole question was one of the conservation of energy, and, in plain English, what these people expected was "perpetual motion." He would, however, point out that gentlemen who listened to these arguments might remember that the chief expense they were called upon to pay was that for wiring and fittings, an expense which would be the same whatever the source of the electricity. With reference to tenant right, £50 to £60 of every £100 was for wires, &c., laid into the wall or permanently fixed, and he might state that the Attorney General, whose absence they deplored that night, had completely confirmed him on this point. With regard to overhead wires, if they could be carried as Mr. Addenbrooke suggested, that would certainly be the least objectionable way; but they must all know that in every street there were some cantankerous persons who refused their consent, and the wires had to cross the street and back again. This could very often be seen with telephone wires, at present in use, and what it would be with a complete system of electric light distribution it would be difficult to imagine. In America they had tall wooden posts down the side of the streets, but Londoners, though they will bear a great deal, would certainly draw the line at that. In advocating culverts he had he said thought it preferable to bring forward a scheme which is definitely practical, it is practical to have culverts in London, it is not to have posts or overhead wires for an extended system. With regard to expense for gas heating, it must be remembered that gas is now produced for lighting, and can be made much more cheaply for heating purposes; and as regards the objection made to the smell, if proper flues were made there was no more need to fear noxious fumes than the smoke of our fires. He could only say that, having used gas for heating at his own house, the servants were much better pleased, and he had experienced no trouble with fumes. As to the question of water power, there was a good deal of misconception on this point. In the first place, we have not much water power in England, and none in London; in the second place, for such a

system of distribution as he was advocating—if we had, the advantage would not be very great. The cost of steam engines is now so small and fuel and upkeep so cheap, that the cost of maintaining water works, dams, and races, would almost equal the total cost of engine power. In fact, with the total cost of installation of £59,000, there is only £2,100 a year for motive power, and if this were entirely swept away it would probably be quite equalled by the cost of interest on capital and upkeep of water works. The question of certainty was very important: nothing, he thought, did so much harm to the spread of the light as those sudden failures, and although they must not criticise a new system like the Grosvenor too much, yet he might state that at Kensington Court, for which he was consulting engineer, where accumulators were used, they had been working some 15 months, and had not had a single light go out from failure of current. He thought this was noteworthy, as the same thing could hardly be said even of a new gas company. At Vienna, again, they had been working for some years with accumulators without extinction or hitch of any kind.

A vote of thanks to the Chairman Col. Hamilton, R.E., in place of the Attorney-General concluded the meeting.

PARLIAMENTARY INTELLIGENCE.

THE CENTRAL TELEGRAPH OFFICE.

Mr. Fenwick asked the Postmaster-General whether it was true that the Treasury recently discovered that clerks employed at the Central Telegraph Office had for the past 18 years been paid a day's pay too much, whether two days' pay was deducted from the salaries of the staff after one week's notice, whether, as a consequence of this discovery, fortnightly payments had been abolished, and whether the clerks had complained of such change having been made in the mode of payment, and, if so, whether he would consider the advisability of paying these clerks weekly, as was done in several other branches of the Post Office service.

Mr. Raikes—In reply to the hon. member, I have to state that the overpayment to which he alludes in his question was brought under my notice by the Comptroller and Auditor-General. Most of the officers employed at the Central Telegraph Office are paid on a scale of annual salaries, and in consequence of payment being made fortnightly an extra day's payment was made in ordinary years, and two days' extra payment in leap years. The question having been referred to the Treasury, it was decided that from and after the 31st of March, 1887, the actual annual salary only should be paid, and consequently, in making the last payment for the year to the 31st of March last, being leap year, the extra payment for two days was made. As I was unwilling to alter the period of payment, I gave instructions that an advance of salary, calculated to the nearest pound, should be made in the middle of every month, the balance being paid at the end of the month. And I do not think it would be the wish of the officers that their wages should be paid weekly.

THE POST OFFICE IN EDINBURGH.

In answer to **Mr. Wallace**,

Mr. Raikes said: The office of the surveyor of the Midland District of Scotland is not part of the establishment of the Post Office in Edinburgh. In accordance with a rule applicable to the whole of the United Kingdom, the surveyor's stationary clerks are borne on the establishment of provincial post offices. The Post Office on the establishment of which the stationary clerks to the surveyor of the Midland District of Scotland are borne is Dundee, and it is only the salary which they would receive were they employed at Dundee that they receive as stationary clerks. Over and above this salary they receive a special allowance, but it is not the case that, in consequence of the withdrawal of two members of the Dundee establishment to act as stationary clerks, any one at Dundee performs higher duties or receives a lower salary than he otherwise would—the establishment having been specially adjusted to provide against such a contingency.

RAILWAY COMPANIES AND THE POST OFFICE.

Mr. Thomas asked the Postmaster-General whether the monopoly, in virtue of which he had directed railway companies to discontinue the conveyance of letter "per rail," was conferred upon the holder of his office prior to the introduction of the penny postal service; whether any further powers had been conferred, in this respect upon the Postmaster-General during the past half-century; whether any of his predecessors in office had ever interfered with the practice of sending letters needing expedition by rail, and whether, pending the inquiry by a departmental committee, he would allow the practice to be continued.

Mr. Raikes—The monopoly referred to by the hon. member was conferred upon the Postmaster-General long prior to the introduction of penny postage, and has been continued by various statutes up to the present time. There has been no extension of the Postmaster-General's powers in this respect since the Post Office Acts of the first year of her Majesty's reign. Representations have been made from time to time by successive Postmaster-Generals to various carrying agencies as to the illegal carriage of letters. For my own part, I will say that, while every effort shall be made to effect an arrangement which shall be convenient to the public, and at the same time legal, I have not the power to sanction the revival of a practice which the law forbids.

COMPANIES' MEETINGS.

WEST INDIAN AND PANAMA TELEGRAPH COMPANY.

A meeting of the shareholders of the West Indian and Panama Telegraph Company Limited, was held at Winchester House on Wednesday, **Mr. C. W. Earle** presiding.

The **Chairman**, in moving the adoption of the report, said the result of the half year's work was most successful, considering that it was the poorer half of the year. It was the most profitable half year since 1883. Most of them would be aware that the sugar crop took place in the first half of the year, and caused a good deal of telegraphing in connection with those crops. Therefore, the second half was not so successful in the way of revenue. The amount they received per mile was not equal to that of other transatlantic telegraph companies. As was the case in 1883, they had had a certain number of windfalls. They had had in the first place an increase of revenue, and in the second place they had chartered one of the ships to the National Ocean Company, which had relieved them of the maintenance of the ship, as well as earned money for the Company. In addition to these two circumstances there had been a profit on the exchange, which, generally speaking, caused a loss. They had also saved £250 on debentures. These combined enabled them to pay 10s. per share on account of the arrears of dividend on the First Preference shares. The amount added to the reserve fund was equal to the calculated amount of depreciation. That fund was well managed, and at present prices was worth £8,000 more than put down at. The repairs to the Porto Rico cable had been most expensive. It had cost altogether £31,000 in addition to, to say nothing of the cost of the ships employed in the work. It was, however, absolutely necessary for them to carry out the repairs, inasmuch as the bulk of their work lay eastward of Porto Rico, and until this work was done they were depending for the bulk of their income upon one cable. When the report was issued, he had hoped to be able to say, for the first time, that all the cables were in working order. But since the report was issued there had been a breakdown in the St. Vincent-Bartholomew cable, which was one of their single systems. The engines were, in consequence, negotiating for a duplicate cable, but as it was an uncommensurate line, owing to the conditions under which it was put down, the Company had pointed out that unless there was a modification of these conditions, they could not invest more money in an uncommensurate undertaking. They were quite ready to meet the engines half way. After stating that there was nothing in the accounts to call for remarks, the Chairman concluded with a sad reference to the death of Mr. W. Althorpe, especially to his connection with this Company.

Mr. Morton said the report did not give the figures for the year, but he would do so. Their earnings in 1887 were £91,949, but the interest on investments did not figure in the report. They brought the receipts up to £96,297. The entire expenses, including interest on debentures, was £45,870 for the year. He calculated that this was sufficient to pay the interest on the preference shares, and leave 5s. on the ordinary shares. This being the case he was surprised shareholders were content to sit down and receive nothing. The fact was, like the boys of Dethley's Hall, they had had all the fun and all the money by ill usage. They were in a splendid commercial position, and yet were reaping no advantage as shareholders. They were earning 5s. on each ordinary share, and yet the shares were selling at 2s. in the £. They had a reserve fund of £130,000, and £10,000 in addition. Yet because of the arrears of interest, which amounted to £53,000, the ordinary shareholders were getting nothing. The matter might easily be put upon a fair basis in a few months by getting a short Act of Parliament passed. Why should it not be done? If the arrears were paid off, then £10 shares would be selling for £5, instead of a miserable 2s. in the pound. He could afford to wait, but there were hundreds of small shareholders who could not. There was no need to wait for an improvement of business. They were already in a state of prosperity, and if the Directors would adopt this policy, they would make the Company a commercial success, instead of one of the greatest failures ever known. If they were too poor, why did they pay 2,000 guineas a year to the Directors in fees? A poor bankrupt company ought not to do it. It was monstrous, and he should not fail to lift his voice up against it until such a state of affairs was removed. He was one of the largest shareholders of the Company, and he should not cease to complain. The shareholders treated the Directors liberally, and ought to be treated liberally in return. He wished to move, "Resolved that until the arrears of dividend on the first and second preference shares are paid off, no further sums be placed to the reserve fund."

The **Chairman**: It is not competent for you to move a resolution of which no notice has been given. It is, besides, a resolution affecting one of the fundamental articles of association.

Mr. Morton: I move it as an amendment to the report. I think I know sufficient of the procedure of company meetings to know I have a right to do so. I protest against its not being received.

The **Chairman** declined to receive the resolution.

Mr. Firth said the question of utilising the reserve fund to pay off the arrears of interest was one for the directors. Inasmuch as they had now an available balance per annum of £17,000, three or four years would suffice to pay off the arrears. They could, therefore, look forward to the future with satisfaction, and might now bury the hat-net. He would like to know, however, if the Directors did not now think the reserve fund large enough.

The **Chairman** urged the absolute necessity of preserving the reserve fund intact. Was it right for a company employing a depreciative plant not to set aside a sum calculated to represent the depreciation of it? That was the crux of the whole question. The Directors estimated that they wanted the reserve fund at about what it was now. But

this time next year they would have to add to it another year's depreciation.

After some further discussion the report was agreed to. Messrs. W. Earle and W. Ford were re-elected Directors.

LONDON-PLATINO BRAZILIAN TELEGRAPH COMPANY.

The tenth ordinary general meeting of the London Platino Brazilian Telegraph Company, Limited, was held on Tuesday at Winchester House, Old Broad Street.

Sir John Pender presided, and, in moving the adoption of the report and the declaration of a dividend of 3s. a share, reminded them that at the last ordinary meeting, a year ago, he referred to negotiations that were going on with the Brazilian Government and with the Western and Brazilian Company with a view to the latter taking over the management of the Company's affairs. Those negotiations had terminated and meetings had been held approving the arrangements which had been come to between the two companies.

Mr. Francis Pavy seconded the motion, which was agreed to.

The resolution passed at the meeting on the 27th ult., approving the agreement with the Western and Brazilian Company, was afterwards confirmed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

At a special general meeting of the Western and Brazilian Telegraph Company, Limited, held on Tuesday, at Winchester House, Old Broad Street, Mr. W. Andrews in the chair, the resolutions passed at the meeting on the 26th ult. were confirmed. They were for making certain alterations in the articles of association of the Company, approving the agreement made with the London Platino Brazilian Telegraph Company for acquiring that company's undertaking; and for increasing the capital of the Company to £1,500,000 by the issue of 30,090 shares of £15 each, to rank *pari passu* with the existing ordinary shares of the Company.

WOODHOUSE AND RAWSON, LIMITED.

An extraordinary general meeting of the shareholders in Woodhouse and Rawson, Limited, was held on Tuesday at the City Terminus Hotel.

Lieutenant-General Sir John Stokes, who presided, stated—referring to the object of the meeting—that it would have been competent for the Directors to have declared an interim dividend, and to have made a further issue of shares without calling a general meeting, but they had thought it better to act as they had done. They had submitted a balance-sheet, which would show that the Directors' decision as to the interim dividend was justified, and it would enable the shareholders to form an opinion on the position of the Company. The first half year's working had given them a profit of over 40 per cent. per annum, but the Directors would declare a dividend at the rate of not more than 12 per cent. per annum. They thought it more prudent to carry the remainder—more than £8,000—to the current half year, especially as it consisted principally of shares in other companies, which were growing in value. Since the formation of the Company they had acquired some valuable patents at a merely nominal price. The actual amount of working capital brought into the business on its being turned into a limited company was only £2,855, the Board having considered it advisable at the formation of the Company to begin with a small capital and gradually to extend the business as they saw fit, the interest paid on advances from the bankers being nominal compared with the profit made. As to the increase of capital now proposed, he might mention that large contracts for lighting, the pushing of patents abroad, and the manufacture of plant at home required them to be out of their capital for considerable periods. They had now decided on issuing 6,000 of the ordinary shares on which they proposed to call up by the 1st of July 35s. a share—this same amount as had been called up on the first issue—and £30,000 in 6 per cent. first mortgage debentures of £100 each, on which £15,000 would be paid up by the 1st of July, and the remainder by the end of the year. Important negotiations, which had extended over many months, and which would lead to a large extension of their business, had been brought to a satisfactory conclusion.

In answer to a question, the Chairman stated that at the outset only 14,000 of the shares were placed at the disposal of the public. The issue now proposed was part of the original capital.

PROVISIONAL PATENTS, 1888.

MAY 4.

6657. Improvements in secondary batteries or electric accumulators. Benjamin David Williams, Bristol Bank Buildings, Bristol.

6680. Improvements in electric railways. George Edward Vaughan, 57, Chancery-lane, Middlesex. (Samuel Trott, Nova Scotia.)

MAY 5.

6740. An improved portable electric lamp. James Turbotton Armstrong and Auguste Sarsadine, 8, Quality court, London, W.C.

MAY 7.

6772. Improvements in electrical measuring, testing, and other apparatus. Theodore Calliphonias, 14, Arundel square, London, N.

MAY 8.

6828. An instrument to be called the "Automatic teleautograph." Frederick James Tolehard, Bradford Lodge, Pargnton.

6834. An instrument for the measurement of the co-efficients of electro-magnetic induction. Arthur Prince Chattock, University College, Liverpool.

6836. An electro-dynamic relay for constant or varying currents. William Edward Ayton, John Peery and David Cook, The City and Guilds of London Institute.

6876. Improvements in apparatus for measuring electric currents. Hermann Aron, 6, Lord street, Liverpool.

MAY 9.

6889. Improvements in dynamos and motors. Oliver Firth and Edward Wright Crabtree, Starbridge Chambers, Bradford, Yorkshire.

6893. Improvements in electro-magnetic and magneto-electric generators. Edward Cox Walker, Darlington.

6907. Improvements in storage batteries. Moritz Immisch, 52, Chancery lane, London.

6909. Apparatus for use with dynamo-machines. Edward John Houghton, 1, Pilkington-road, Peckham, London, S.E.

6910. A system of electric lighting. Edward John Houghton, 1, Pilkington-road, Peckham, London, S.E.

6927. Improvements in electrically propelled vehicles, and appliances connected therewith. Michael Radcliffe Ward, 55, Chancery lane, London, W.C.

6928. Improvements in electric switches. Frederick Wilhelm Andersen and Jean Forwood late, 3, E. court, Temple, E.C.

6953. Improvements in electric gas-lighters. William Southern, 6, Lord street, Liverpool.

MAY 10.

6986. Improved switch for electrical tramcars. Moritz Immisch, 52, Chancery lane, London.

6988. Improvements in the method and means of supplying electrically-worked vehicles with fresh sets of accumulators or equivalent sources of electricity. Michael Radcliffe Ward, 55, Chancery lane, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MAY 2, 1887.

6400. Improvements in electro-magnetic apparatus for the automatic lighting and extinguishing of gas lamps. Johann Rudolf Schiller and Christian Meyer, 115, Cannon-street, London.

MAY 17, 1887.

7189. Improvements in secondary batteries. William Hopkin Akester, 57, Chancery lane, London.

JUNE 7, 1887.

8206. Apparatus for effecting by insertion of a coin the production of electric light for a certain time. Dixon Henry Davies and John Mesny Tourtel, 28, Southampton buildings, Chancery-lane, London, W.C.

JUNE 13, 1887.

Improvements in electric lamps. Alexander Melville Clark, 53, Chancery-lane, London. (Camille Deaton, France.)

JULY 7, 1887.

9596. Improvements in electrical apparatus for working railway signals. Illius Augustus Timmis, 2, Great George-street, Westminster, London, S.W.

MARCH 2, 1888.

3246. Improved electrical lamp and projector, and method of applying same for maritime and other purposes. Frederick Walker, 4, Little Moorfields, London, E.C.

MARCH 3, 1888.

3303. Improved apparatus for registering the consumption of electric energy. Henry Hamington Leigh, 22, Southampton-buildings, Chancery-lane, W.C. (Jean Louis Clerc, Paris.)

APRIL 7, 1888.

5203. A method of and apparatus for transmitting sounds to a distance by means of light. Leon Jules Le Pontons, 28, Southampton-buildings, London, W.C.

SPECIFICATIONS PUBLISHED.

1887.

6221. Governing by electro-chemical action, &c. A. Shippey and W. J. L. Hamilton 11d.

6581. Holders for electric lamps. E. Mauville and W. L. Madgen.

7265. Phonic reception of electrical signals. C. Ader. 8d.

9853. Dynamo-electric machines. H. Watt. 8d.

16,709. Electrical generators. T. A. Edison. 8d.

1888.

633. Dynamo-electric machines. U. Cooper. 8d.

734. Galvanic batteries. J. Noul. 8d.

3483. Electrical switches. F. T. Schmitt. 6d.

3685. Electrical switches. S. Shapard and others. 8d.

CITY NOTES.

Change of Address.—The Electrical Automatic Delivery Box Company, Limited, has taken offices at 45, Eastcheap.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended May 11 amounted to £4,312.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ended May 11, after deducting the fifth of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, were £3,561.

Companies of the Month. The following electrical companies were registered during the month of April:—

Telephone Union, £5 shares	£10,000,000
Kensington and Knightsbridge Electric Lighting Company, £5 shares	250,000
Tunbridge Wells Electric Light Company, £5 shares	30,000
Protest Battery Synchrate, £10 shares	5,000
Electric Date and Time Stamp Company, £1 shares	100,000
Bournemouth Electricity Company, £5 shares	50,000
United Kingdom Telephone Union, £5 shares	10,000,000
Southampton Electric Light and Power Company, £5 shares	30,000

Hastings Electric Light Company. The following report of Directors will be submitted at the ordinary general meeting, to be held at the Electric Light Works, Earl street, Hastings, on Tuesday, 22nd day of May 1888, at four o'clock in the afternoon precisely:—The Directors present herewith their statement of accounts for the year ending 31st March, 1888. The Company is now supplying 30 arc and 864 incandescent lamps as against 30 arc and 704 incandescent lamps last year, again showing an increasing business. The Directors have every reason to believe that by laying down mains in new districts and increasing the plant, the demand for supply of electric light will enormously increase. The principal hotels are now lighted by electricity with very satisfactory results, and applications are being made to substitute incandescent lighting for gas in places of worship and business establishments. On referring to the profit and loss account it will be seen that the gross profit for the year amounts to £558 18s. 14d., but from this must be deducted

interest on overdraft at bankers and on debenture bonds, issued to the amount of £1,000, thus leaving a balance of £514 9s. 4d., out of which the Directors propose paying a dividend of £3 per cent., free of income tax, amounting to £204 10s., and carrying forward the balance to next year's account. The suggestion of the Directors at the last annual meeting of the shareholders, as to raising a sum of £5,000 by means of debenture bonds, was not carried out, but a sufficient number of shareholders were found willing to take up bonds to the amount of £1,000, bearing interest at 5 per cent per annum. The Company's bankers, Messrs. Beeching and Co., kindly agreed to reduce the rate of interest on overdraft to 25 per cent. The revenue account shows that a sum of £166 6s. 3d. has been charged to that account for repairs to boilers, including a new fire box put in by Messrs. Robey and Co., of Lincoln. Messrs. Reeves, Langham, and Woodhams are the retiring Directors, and offer themselves for re-election. The Auditors, Messrs. Hart, Brothers, Tibbatts and Co., retire, and offer themselves for re-election.

Lawrence Light, Heat, and Power Company of London, Limited.—Registered by Ashurst, Morris, Crisp, and Co., 6, Old Jewry, London, E.C. Capital £250,000, divided into 50,000 shares of £5 each. Object: to carry into effect an agreement expressed to be made between the Lawrence Automatic Gas Company, Limited, of the one part, and the Company of the other part, to carry on the business of makers and suppliers of gas or any other illuminants, and manufacturers of and dealers in lighting and heating apparatus and appliances of all kinds. The first subscribers are:—

Share.	Share.
J. D. Chapman, 64, Wellington street, Woolwich	1
E. T. Botwright, accountant, 23, Sutton place, Hackney, E.	1
F. T. Marney, clerk, 12, Bradley road, Wood Green	1
F. Chapple, solicitor, Claremont road, Highgate	1
E. S. Harper, accountant, Goodrich road, East Dulwich	1
J. Alexander, accountant, Danby street, Peckham, S.E.	1
W. C. Horton, 297, Crystal Palace road, Dulwich	1

The number of Directors shall not be more than seven nor less than three, and the first shall be appointed by the subscribers to the articles of association. The qualification shall be the holding of not less than 50 shares in the capital of the Company. The remuneration shall be fixed by the Company in general meeting.

NOTES.

Madras.—Arrangements are being made to introduce electric motor cars into Madras.

Barnet. The contract between the Barnet Local Board and Mr. Joel for lighting the town by electricity has been signed and sealed.

Japan.—The Mikado has commissioned a Japanese engineer to visit the States, to gain information with the intention of introducing electric railways into Japan.

Tender. The London and County Land and Building Company, Limited, are prepared to receive tenders for the electric lighting of their Lombard street and Drapers' gardens estates.

Mather Steam Dynamo. The Mather steam dynamo illustrated last week consists, we are given to understand, simply of Mr. Arthur Riggs' rotary engine, with the addition of the wiring.

Hamburg.—The work of installing the electric light at the free port and docks of Hamburg is actively in progress, and comprises 50 arc lights and about 4,000 16 c.p. incandescent lamps.

Society of Telegraph-Engineers. The paper to be read at the meeting to be held on Thursday, May 31st, is "On the Influence Machine, from 1788 to 1888," by Prof. Silvanus P. Thompson.

Gas v. Electricity.—An official report says the working expenses in connection with the lighting by electricity of South Kensington Museum amounted to £1,224. Gas would have cost £2,845.

St. Catherine's Lighthouse. The authorities at Trinity House have superseded the fixed oil light at St. Catherine's lighthouse for a flashing electric light, showing one flash of five seconds' duration every half minute.

Strand. The question of lighting the streets in the district with electric light was brought up by the Lighting Committee of the Strand district at the meeting last week, but in view of legislation they recommended no steps be taken at present.

Weston-super-Mare.—The Weston-super-Mare Town Commissioners have instructed the Finance Committee to report upon a proposal for the adoption of the electric light. The cost is estimated at £20 per lamp per annum, equal to a rate of 1d. in the £.

Lord Salisbury and Technical Education.—The Marquis of Salisbury has consented to move a resolution in support of the proposed South London Polytechnic Institute, and the necessity for technical education in this country, at a public meeting to be held at the Mansion House on June 8.

Eastbourne.—The directors of the Eastbourne Electric Light Company, having been asked to supply the electric light till a later hour, have decided, during the ensuing summer months, to run their incandescent lamps till 1 a.m. if the consumption is sufficient to warrant the cost of production. A week's trial will be made.

Stealing Lamps.—Denver, Colorado, has its streets lighted with incandescent lamps. It has lately been noticed many of these lamps have been broken or stolen, as many as twenty in one night having been carried off. It is

not known whether it is thieves who have done this, or some person wishing to bring discredit on the light company.

Samples of Light. Mr. W. F. Brown, the agent of the Bernstein Electric Light Company in Minnesota, has hit upon the "brilliant" idea of doing his canvassing with a sample. He takes round a small storage battery capable of running a 40 c.p. lamp for about three hours. This makes a fine display, is very effective, and saves much talk.

House-to-House Supply Company.—For their first central lighting station, at West Brompton, this company has ordered three horizontal coupled compound steam engines from Messrs. John Fowler and Co., three water-tube steam boilers, with water heaters and feed-pumps, from the Babcock and Wilcox Company, and three sets of alternating current dynamo electric machinery from Elwell-Parker, Limited.

Fire Premiums. With reference to the recent discussion on fire risks and the reduction of premiums, we notice the New England insurance companies have agreed to make a reduction in their rates for premises lighted entirely by electricity, with liberty to use gas or oil for not more than ten days in any one year in event of accident to the electric light. Our contemporary, the *Gas World*, says the moral is obvious. There seems to be more than one moral!

Westinghouse Meter.—Mr. Otto A. Moses, electrical expert, of New York, has reported upon the new electric meter made by the Westinghouse Company for an alternating current system, and pronounces it a perfect success. It shows the number of hours and candle-light units, and the amount in dollars and cents, so that every man can read and keep his own electricity account. He pronounces it more reliable than any gas meter, and will be largely put in use at once.

Artificial Lightning.—The steam yacht "Warrior," which formerly belonged to Mr. Bailey, of Hull, and is now the property of the Egyptian Government, has been fitted with the electric light at Messrs. Day, Summers, and Co.'s, Northam. She went out for a trial trip on Tuesday, and in the evening a trial was made with the electric light, the flashing with which caused considerable interest in the lower part of the town, a great many in the upper part also mistaking it for lightning, thinking that a storm was coming up.

Electricity is Life.—"Electricity is Life," say the charlatans who announce at immense cost in the current journals the sale of their galvanic belts and rings, magnetic plasters, and other deceptions for the use of devotees. *Electricity is death*, says the Government of New York, who have decreed that condemned criminals shall in future be despatched to Pluto by the means of an electric shock. No doubt this example will be followed in other countries, and here is a new branch created for makers of dynamos.—*L'Electricien*.

Bournemouth.—The Committee of the Improvement Commissioners last week reported that a draft license under the Electric Lighting Act, 1882, was read, and after considerable discussion as to the request of Messrs. Philips, Harrison and Hart for sanction to their application to the Board of Trade, it was moved that the Committee recommend the Board not to give their sanction at present, on the ground that, though the Board would have to give their sanction eventually, it would not be fair or advisable to give the monopoly to one company at the present time.

Kensington Town Hall.—At the Board meeting on May 16 it was moved that the town hall be lighted by electricity, and that the Special Purposes Committee be requested to advise the vestry as to the tenders referred to in their report (dated April 24th) for running mains and wires for supplying electricity to light the town hall and offices, and for the supply of the necessary fittings. An amendment was moved that the matter be deferred for one year, but was lost. A further amendment was moved on the first motion—“That the matter be deferred for three months.” This was carried by 33 to 20.

Political Economy of Motor Cars. Mr. Hewitt, Mayor of New York, advocates tramcars of rapid transit with a speed approaching that of railways; no construction above the surface can give the solidity necessary, therefore he favours an underground plan. Rapid transit by tramcars, he says, will enable us to derive the benefit of increased taxation on outlying districts, for property increases as the square of the velocity of travel. He would have the corporation construct subways, useful also for mains, pipes, wires, &c., and rent them to various companies using them. The enormous expenses of laying down conduits and of taking up the streets perpetually would thus be saved.

Testing for Ores by Telephone.—An interesting application of the sensitiveness of the telephone to currents of weak but varying strength is that of an apparatus patented by Mr. John R. Williamson, Seattle, Washington, for testing rocks for ore, which may probably prove of great utility in mining operations. One pole of a battery is connected by a flexible wire to a wire brush, which can be lightly brushed over the ore to be tested. The other pole is connected to a telephone in the ordinary way, and to a metal plate on which the ore is placed, if a specimen, or to earth if *in situ*. If the rocks contain metal, the contact of the small portions with the brushes complete the circuit, and a scratching sound is heard in the telephone. When no metallic ore is present, no sound is heard.

Nickel Plating.—A new process of nickel plating has recently come into use in Belgium, by which a thick plating of nickel may be deposited on any metal by a feeble electric current in a very short space of time. The bath is composed of 10 parts sulphate of nickel, $7\frac{1}{2}$ of neutral tartrate of ammonia, 0.5 parts tannic acid, and 20 parts of water. The sulphate of nickel is dissolved in three to four parts of water, carefully neutralised, the other ingredients added, and the solution boiled for a quarter of an hour; the rest of the water is added, and the liquid filtered or decanted. By adding the materials in the same proportion, the strength of the bath may be kept constant. It is said that the deposit is brilliantly white, soft, and homogeneous, and has, even when of great thickness, no tendency to scale.

Single Wire System.—The offices of the *Scotsman* newspaper, in Edinburgh, are lighted throughout with incandescent lamps on the single wire, or earth return, system, on which we published a paper recently. The installation consists of about 370 lamps of 16, 32, and 50 c.p., supplied by two 300 light dynamos; in conjunction there is also a battery of 110 accumulator cells, capable of feeding 200 lamps. The positive wire in all cases is insulated, and the switches and fuses are placed on this wire. The return wire is connected to the metal work of the fittings. Main switches and fuses control each department, and a switch is provided to each fitted. The installation was carried out under the superintendence of Mr. J. D. F. Andrews, of the firm of Muir, Mavor and Coulson, Glasgow.

Finsbury Technical College.—The annual *convocation* of the students of the Finsbury Technical College will be held to-night at seven o'clock. Prof. Silvanus Thompson will give a lecture on the “Polarisation of Light” and Prof. Perry on “Magnifying Springs.” A concert will be held during the evening, and there will be an exhibition of scientific apparatus. Tickets may be obtained at the College, Leonard Street, E.C. The next meeting of the Old Students' Association will take place at the Finsbury College, on Tuesday, May 29, at 7:30 p.m., when Mr. Reginald J. Jones, A.S.T.E., will read a paper on “Some Installation Breakdowns.” This will deal with all aspects of the question of breakdowns in electric machinery, arc and incandescent dynamos, gearing, motors, circuits, arc and incandescent lamps, fuses, &c.

Birmingham.—A project is now on foot to light a portion of the central part of the business premises of Birmingham. The authorities of the Old Library, Union-street, consulted Messrs. Chamberlain and Hookham on the question of lighting the Library, and it was found necessary to obtain premises for machinery outside. To justify this expense other persons near were asked to join, and the scheme has become quite a central installation. Messrs. Chamberlain and Hookham have marked out a district bounded by High-street, New-street, Corporation street, to Union-street. This district can be conveniently lighted from a central station, provided the consumers will give their consent to have the distributing wires fixed to their premises. It is proposed to supply the light by meter on terms similar to those at Liverpool, where a private central station lighting is under sanction of the Town Council and Board of Trade.

Admiralty.—The Engine-room Telegraph Committee, which have been sitting at Portsmouth for more than a year, have now prepared their report. As a consequence of their experiments and deliberations, it has been determined to fit the whole of the ships of the Admiral class with electric, in addition to the usual mechanical, telegraphs for communicating between the bridge and the engine-room. As the ventilation of the dynamo flats in these ships is so bad that it is well nigh impossible for the men to live in them for any length of time, it has also been resolved to provide them with peace fittings in the shape of additional dynamos. These will be placed on the main deck and will be of 100-ampere power. In time of war the service dynamos, which are below the water-line and are protected from shot, will be used for the search lights and glow lamps. Another innovation is to be introduced whereby four projectors will be fixed in each of the Nordenfjeldt projections at the corners of the superstructure deck, so that in case of an expected torpedo attack the ships will be able to surround themselves with radial beams of light.

Queenstown.—At the meeting of the Queenstown Town Commissioners on Wednesday the subject of electric lighting was brought before them by Mr. Carbery, who stated that when recently in London he had inquired into the subject of electrically lighting the town, and had come to the conclusion that if the commissioners undertook to supply the light to the shopkeepers, they would be able to do so, and, from the income received, get the town lighting free. We have carefully read the report of this meeting as given in the *Cork Daily Herald*, and feel convinced that Mr. Carbery must have misinterpreted the information given to him. His estimate seems to be founded on an arc lighting system solely, with overhead wires, and not sufficient attention has

been given to the incandescent lighting for the interior. At any rate it was decided to advertise only in the *Freeman's Journal*, the *General Advertiser*, and *Investors' Guardian* for tenders. It may be that many of our readers will consult the columns of these papers, otherwise we fear the Queens-town authorities will not have much difficulty in comparing the tenders.

Electric Lighting in Luxemburg.—The houses in the little village of Hesperange, near Luxemburg, the first station on the Mondorf and Remich Steam Tramway, are lighted by incandescent electric lamps, maintained by a dynamo worked off a flour mill engine. In this way the light does not become expensive, but has the disadvantage of being intermittent according to the exigencies of the mill. The Steam Tramway Company, too, complains of induction to its telephone wire through the propinquity of the lighting leads, so that, now the Hesperangers have got used to the electric light, it is probable they will have an independent installation. The village of Rosport, and the town of Echternach are also electrically lighted by Mr. Henry Tudor. The latter place is provided with from five to six hundred incandescents of 6, 8, 10, 16, 25, and 35 c.p. besides a 1,000 c.p. and two 500 c.p. arcs in the old Basilica. These are maintained by a Schuckert and a Spiecker dynamo, driven by a 16-c.p. horizontal engine by the Gebrüder Pfeiffer, which is run from 8 to 11 p.m., after which current is supplied by accumulators. A sum of 3fr., or half-a-crown is charged for a 10 c.p. lamp per 100 hours. The installation was started on 1st November last year.

American Institute of Electrical Engineers.—The general meeting for the reading and discussion of professional papers was held on Wednesday, May 16th, and the following papers read: "On a new system of Alternate Current Motors and Transformers," by Mr. Nikola Tesla. "The Possibilities and Limitations of Chemical Generators of Electricity," by Mr. Francis B. Crocker. "Underground Electrical Systems in Europe and America," by Prof. G. W. Plympton, of the Brooklyn Subway Board. "On Compensated Resistance Standards," and "On Prof. Moler's 'Swinging Arm' Galvanometer," by Prof. Edward L. Nichols, of Cornell University. "The Patent Court and Uniformity in Patent Practice," by Mr. George H. Stockbridge. "Protection of the Human Body from Dangerous Currents," by Mr. P. B. Delaney. Mr. Emile Berliner, of Washington, member of the Institute, has devised an apparatus which he calls a "molecularium," and by means of which, adopting the theory of molecular vibration, he explains and illustrates a large variety of electrical phenomena, including those connected with static charge and discharge, voltaic current, heat, &c. Mr. Berliner has presented to the institute a model of this apparatus, which was exhibited at the meeting.

Telegraphing from Trains.—The fact that all the other telegraph lines were down during the late blizzard in America, and that the train-telegraph line remained entirely intact, was due to the method of construction on the Lehigh Valley Railroad, the plan being to use only stout wooden poles, firmly and strongly set in the ground, with no cross arms, and carrying a single wire. No storm could break down wires thus fixed, for what test could be severer than the late blizzard? If, then, this is so, why do not the railway and telegraph companies realise the utility of this method of fixing for at least part of the wires independently of the advantage of communicating to trains? With regard to the latter question,

the advantages are evident on the surface. One who was blocked in a train in a snowstorm, and kept for hours without possibility of communicating with the outside world, asks with reason, Why do not the railroads appreciate at once the enormous advantages of this system, and the great convenience and comfort it would be to their passengers, and also a source of profit as well to the railway company having the sagacity, foresight, and enterprise to adopt this wonderful and extremely practical system of telegraphing from trains? Many would gladly give sums of five shillings or a pound for the chance of communicating during a block by telegraph with anxious friends and families.

Coast Telegraphy. Mr. Bayley, writing to the *Times* on the Earl of Onslow's Bill to give Lloyd's power to purchase land for signal stations, and thus improve the electrical communication on our coasts, gives the following information as to what Denmark has done in this direction. He says: We have only to go to Denmark to find that electrical communication of the best kind has been provided by the Government on the west coast of Jutland, and, in the Kattegat, telephone lines are laid to the lifeboat and rocket stations, which connect them with the inland telegraph stations. The telephone stations are served by the man or woman who may be on the station, and they are allowed to charge about 3½d. for each message or telegram sent off. For those received no charge is made. The lines are laid chiefly in the interests of the fishermen, and, as they serve both lifeboat and telephone stations, they use them very freely among themselves for market purposes, as well as in case of shipwreck and for private information. In the year 1887 the following messages were received and sent from the telephone stations:—Received from Denmark, 2,560 messages; received from abroad, 619 messages; sent off to Denmark, 3,162 messages; sent off to abroad, 1,314 messages; 1,807 communications were also held between the various stations. At the Skaw, Hirtshals, and the Hirtsholm lighthouses the keepers act as telegraph clerks. They advise the Copenhagen exchange of all ships that signal as they pass, and report information about weather, wind, shipwrecks, &c., to those who desire to know.

Leamington.—The Tramway Company at Leamington asked permission of the Town Council to experiment with an electric tramcar. This was given subject to the approval of the town clerk, who was to see that no injury was done to the roadway. At a stormy meeting in which the electric light at Leamington was freely discussed, Councillor Crowther Davies moved that twelve months' notice be given to the company to terminate the arrangement. That the company were supplying shops and private individuals with light satisfactorily, he was well aware. He stigmatised the street lighting as in the highest degree unsatisfactory—"A yellow incandescent wire flickering in a finger-glass at the end of a gibbet—hardly equal to those sold at a shilling a box, known as Price's patent night lights." He said there were as many as eleven lights out on one night, and that they were not more than 8 c.p. Councillor Mansfield sympathised with the company, who had been experimenting with their own money, but still he regarded the electric light as a dismal failure. Still, he would not support the motion, as he should like the company to have an opportunity of offering the town something better than they had at present. Others thought that the light was neither a success nor a failure; that it was better

than the old system, but not what they wished to see, that the company should have fair play, as they had already spent £30,000. The Mayor considered the light had been a success, and, that after the company had spent so much money, it would be most unfair to carry such a resolution. On the vote being taken, there were 10 in its favour and 10 against it, and the matter remains *in statu quo*.

The Telephone.—The following letter is from the *Sunderland Daily Herald*, May 16: "Sir, I should like to call your attention to a very objectionable custom that promises to convert the telephone into a positive nuisance. The custom referred to, which must have proved a great annoyance to all who have had occasion to visit offices using the telephone, is as follows: If you are conversing with a gentleman on any subject, no matter how important, and the telephone bell rings, he abruptly leaves you and flies to the instrument as though it were his master and he its servant, or rather its slave. I do not know whether it is the novelty of the affair, so that we must regard it as a case of a child and new toy, but at all events such is the custom; the gentleman leaves you, though you may be in the middle of a sentence, and you are doomed to that eternal one-sided business: 'Are you there?' 'Five pounds per ton.' 'No.' 'Yes.' 'Yes.' 'Yes, but I think oil's better,' and so forth. When all is over your polite (?) gentleman, without apology, resumes the conversation with you. Now, let us see what all this means. It means simply this, that you take the trouble to go from your office to see a gentleman, whilst my lord impatience at the other end of the wire does not. You get possession of the child who has the toy, and you are entitled to keep him against all comers till done with him. Indeed, everyone waiting in the ante-room when the bell rings is entitled to precedence as against the individual who takes his ease at the other end of the wire. Nay, I will even go further, and contend that everyone who arrives before the distant telephomist could have reached the ante-room ought to come before him. Now, whilst the practice is its infancy, is the time to teach these gentry manners, or it may get too strong for resistance. Those who have the power should distinctly decline to be made a convenience of for the benefit of anyone who, though he may be able to afford the telephone, is not on that account entitled to sit in his office and, into the bargain, gain an unfair advantage over those who have taken the trouble to make a journey. If the custom does not amount to rudeness and impudence, it 'sails very close to the wind.' What on earth is there in the telephone to give such precedence?—Yours obediently, VIRTIM."

British Association. The 58th annual meeting of this association will take place at Bath, beginning Wednesday, September 5, the President will be Sir Frederick J. Bramwell, D.C.L., F.R.S., M.Inst.C.E. The section most interesting to electrical engineers will be those of: A.—*Mathematical and Physical Science*.—President, Prof. G. F. Fitzgerald, M.A., F.R.S.; vice-presidents, Captain Abney, R.E., F.R.S., F.R.A.S., F.C.S., William Esson, M.A., F.R.S., F.R.A.S., F.C.S.; secretaries, R. E. Baynes, M.A. (recorder), R. T. Glazebrook, M.A., F.R.S., Prof. H. Lamb, M.A., F.R.S., W. N. Shaw, M.A. B.—*Chemical Science*.—President, Prof. W. A. Tilden, D.Sc., F.R.S., V.P.C.S.; vice-presidents, Prof. Odling, M.B., F.R.S., V.P.C.S., W. H. Perkin, Ph.D., F.R.S., V.P.C.S.; secretaries, Prof. H. B. Dixon, M.A., F.R.S., F.C.S., H. Forster Morley, M.A., D.Sc., F.C.S. (recorder), R. E. Moyle, B.A., F.C.S., Dr. W. W. J. Nicol, M.A., F.R.S.E. G.—*Mechanical Science*.—Pre-

sident, W. H. Preece, F.R.S., M.Inst.C.E.; vice-presidents, W. Anderson, M.Inst.C., W. Shelford, M.Inst.C.E.; secretaries, C. W. Cooke, W. Bayley Marshall, E. Rigg, M.A. (recorder). H.—*Anthropology*.—President, Lieutenant-General Pitt Rivers, D.C.L., F.R.S., F.G.S., F.S.A.; vice-presidents, J. Beddoe, M.D., F.R.S., J. Evans, D.C.L., LL.D., Treas. R.S., F.S.A., F.L.S., F.G.S.; secretaries, G. W. Bloxam, M.A., F.L.S. (Recorder), J. G. Garson, M.D., F.Z.S., M.A.I. The first general meeting will be held on Wednesday, September 5, at 8 p.m. precisely, when Sir H. E. Roscoe, M.P., D.C.L., LL.D., Ph.D., F.R.S., F.C.S., will resign the chair, and Sir F. J. Bramwell, D.C.L., F.R.S., M.Inst.C.E., president elect, will assume the presidency, and deliver an address. On Thursday evening, September 6, at 8 p.m., a *soirée*; on Friday evening, September 7, at 8.30 p.m., a discourse on "The Electrical Transmission of Power," by Prof. W. E. Ayrton, F.R.S.; on Monday evening, September 10, at 8.30 p.m., a discourse on "The Foundation Stones of the Earth's Crust," by Prof. T. G. Bonney, D.Sc., LL.D., F.R.S., F.S.A., F.G.S.; on Tuesday evening, September 11, at 8 p.m., a *soirée*; on Wednesday, September 12, the concluding general meeting will be held at 2.30 p.m. Excursions to places of interest in the neighbourhood of Bath will be made on the afternoon of Saturday, September 8, and on Thursday, September 13.

Curiosities of Lightning.—Mr. J. D. Dougall, writing to the *Times* from Glasgow on this subject, says.—"Saturday's thunderstorm in the North seems to have been exceptionally heavy. From most reliable private information I learn that at Glasgow 'the air seemed full of forked lightning,' this lightning being incessant, from the remarkable fact that there were two separate storms going on simultaneously, one on the one side of the city, and the other on the other side. The lightning is described as 'something terrible.' It may interest scientists and others to learn that the three boys struck by the lightning on Glasgow-green, as reported in your yesterday's issue, were neither walking nor standing up, but sitting in a row on the grass, and a most respectable person, from whom I have the information almost directly, saw the whole three simultaneously fall over on being struck, and, strange to say, the boy in the middle shortly afterwards sat up again, the other two being killed. That he should survive while the outsiders were killed seems remarkable, and the case may come to be recorded among the many curiosities or eccentricities of lightning strokes. It may be somewhat out of place, after giving the particulars of so sad an accident, to narrate the following; but I do so solely as bearing on the influence of thunderstorms on the lower animals, and not as affecting the gentle sport of angling. Many years ago I was fishing in a tributary of the Cart, Lanarkshire—viz., the Kittock, a brook famous for the large size of its trout, running up to several pounds in weight, and out of all proportion to its small volume of water. I had only seen a few small trout until about 1 o'clock, when a heavy thunderstorm came on, and all at once large fish seemed to rush forth from their hiding places and to feed greedily. I well recollect the lightning gleaming on their yellow sides as they dashed wildly at my flies, so wildly, in fact, as to cause them to miss their aim. I had, however, taken several good fish, when a message was sent from an adjacent farmhouse, imploring me so earnestly to come in out of the storm or I should assuredly be killed, that I could not well refuse, and so an incident unique in my own experience, and such as

I have never heard of in that of others, was cut short. Salmon are known to move and feed during sudden squalls of wind and atmospheric disturbances, but for trout of more than usual shyness, like those in the Kittock, to be moved by a violent thunderstorm seems opposed to all general or popular ideas.

Bath.—At a meeting of the Bath Town Council on Tuesday, the recently-appointed Electric Lighting Committee brought up their report, which consisted merely of a printed tabulated statement, containing a summary of the information the committee had obtained from places where the electric light is or has been in use. The cost in all cases but that of Waterford, where it was the same as gas, was considerably above that of gas; and all the towns gave an unqualified negative to the question, "Do you find the electric works a nuisance?" In presenting this information, the committee stated that they now waited further instructions. The chairman (Mr. Sturges) moved that the Council instruct the committee to obtain tenders for lighting a central area by electricity, and to report such tenders to the Council. He exhibited a diagram of the district it was proposed to light on the new system. At present this district had 273 gas lamps of 20 c.p. each, nine of 100 c.p. each, and four of 80 c.p. each; and it was proposed to substitute for these lamps seventy electric lights. The seventy electric lamps would give a total of 81,000 c.p., or, taking one-third off for obscuration of the light by the ground-glass globes, a net illumination of 56,000 c.p. The illuminating power of the existing lamps was 6,860 candles, so that the electric system would give something like nine times more light. As for the cost, the present cost for lighting the district mentioned was £953 annually, and though the electric light experts originally thought the new system would cost £1,400, Mr. Massingham now assured him he did not believe it would cost more than £300 in excess of the present amount, or about one-third additional. There were several reasons why the cost of the electric light in Bath would be less than elsewhere. The coal requisite could be obtained very cheaply, as Bath stood on the borders of a coal country; there was considerable water power available at the town weirs; and the old slaughter-house site would be a good position for the works. Mr. Sturges then expatiated upon the merits of the electric light, and concluded by observing that his resolution bound the Council to nothing, but only enabled them to ascertain what could be done, how it could be done, and how it could be best done. Several of the leading citizens were willing, if necessary, to form a local company for supplying the light at the lowest possible cost of production. An amendment was moved to add to the resolution the following clause, "And that the committee invite the gas company to tender for supplying a better light than they do at present." Several members thought that if the Gas Company would supply gas of 30 c.p. it would be as great an advantage to the citizens as the introduction of the electric light. Major-General Burn said he should be very sorry to find the question of gas introduced into the resolution, for not only did he look upon the electric as a much better illuminant than gas, but also as being safer for the city. If they had their streets lit with it they would get it introduced into the theatre, hospital, and other public buildings. Several members thought that even if the Gas Company could be induced to raise the illuminating standard of the gas supply to 30 c.p. it would still be unable to compete with electricity, and fail to satisfy the requirements of the citizens. On the amendment being put only six voted for it. The

resolution to advertise for tenders for electric lighting was then put and carried unanimously.

Mather and Platt's Dynamos.—Messrs. Mather and Platt, Salford, who have a recognised reputation for supplying the highest class of dynamos and electric machinery, have just issued a second edition of their catalogue of "Edison-Hopkinson" and "Manchester" dynamos. The "Edison-Hopkinson" dynamo, therein illustrated in its different sizes and types, is guaranteed to give a commercial efficiency of 90 to 94 per cent. (according to size), a result, they claim, higher than any other make in the world. The type giving 320 amperes, 110 volts, at 780 revolutions, was tested with the following results: commercial efficiency 93.23 per cent., loss in core 1.94, in magnets 1.66, in armature 3.17 per cent. The efficiency of the same dynamo used as a motor is 93.79; on the double conversion 87.05 per cent., without loss in leads. The smallness of the loss internally, together with the great care in mechanical details, gives this dynamo great advantages in durability, and a continuous run of three weeks, with an excess of 10 per cent. over its normal load, has been effected with these machines. The great distinction of this dynamo is the extreme intensity of its magnetic field, a feature which enables the machine to be self-regulating within ordinary limits without compound winding. Not the least advantage is complete absence of sparking at the brushes, the commutator showing little wear for years, and the brushes lasting, with care, for a twelvemonth or longer. Each machine has two sets of brushes, so that one set can be adjusted or removed without disturbing the current. A recent improvement introduced into some sizes of the Edison-Hopkinson dynamo is the construction of the armature with copper bars, instead of insulated wire. By this means the amount of copper in a given size of armature is largely increased and the resistance diminished, which enables a larger current to be carried with the same economy. The bar armature has the further advantage, that at no point of the armature do two bars, on which the electric pressure is widely different, come into close proximity, which much diminishes the possibility of a cross or breakdown of insulation ever occurring, should the dynamo not receive proper attention, or be subject to very sudden variations of load. Messrs. Mather and Platt's second type of dynamo—the "Manchester" dynamo—is remarkable, not for any distinctive departure in construction, but for a happy conjunction of all the best-known electrical and mechanical principles of dynamo construction, being small, very compact, and efficient. In some of the larger sizes the efficiency is over 93 per cent. These machines are all compound-wound for incandescent lighting, in sizes from 20 to 350 lamps. They are also supplied series wound for arc lighting. The armature is wound so that no parts of widely different pressure are in close proximity. These dynamos are also used as motors, with a commercial efficiency of 90 per cent. A series of trials, communicated to the Royal Society, showed that the double conversion of h.p. over 100 yards was effected with a total efficiency of 77.5 per cent. At the Manchester Jubilee Exhibition, a calico-printing machine, requiring 20 h.p., was driven by a "Manchester" dynamo, working as a motor, during the whole exhibition. A combined engine and dynamo is also supplied, with short belt and special belt-tightening pulley gear, for use in confined spaces or on board ship. Special dynamos for testing and teaching purposes are made with special switchboard for altering to series, shunt, or compound-wound arrangement.

ARTISTIC FITTINGS.

I.—LAING, WHARTON, AND DOWN.

In our issue of March 9 was given a paper on "Artistic Electric Lighting," which carried a moral to the effect that not only is it necessary to consider such things as volts and amperes, but the cultivation of the beautiful and, generally, artistic effect must not be lost sight of. Our competitors of the gas interests have long paid great attention to the visible fittings of their work, and the effects produced are often pleasing to the eye and effective in the *mise en scene*.

FIG. 1.—Table Lamp with Shade.

The ordinary gas fittings can hardly be classed among the beautiful, and when success is spoken of it refers only to those instances when special designs have been made to agree with the general architecture of the room. When the incandescent electric light was first introduced many thought and argued that no change would be required

FIG. 2.—Double Table Lamp.

in the fittings, and that the old stock of gas fittings might be used up. It is not so. The electric light lends itself to a far greater variety in the matter of fittings than does gas, in that the flame of the latter must necessarily be in all ordinary cases upwards, while the incandescent filament can be placed in any direction required to give a particular effect. This was soon seen, and a few firms commenced to

make a speciality in electric fittings. A large number of beautiful designs have been produced, many examples of which are before us. It is almost impossible to adequately illustrate such designs in black and white, and no doubt an early attempt must be made by means of colours. Still, for the moment, a general idea may be given. Recently visiting Messrs. Laing, Wharton, and

FIG. 3. Electrolier.

Down's new show-rooms, in New Bond street, we were shown a large number of fittings specially designed for electric light purposes. These fittings are all made by hand, of mixed materials—hammered copper and brass—

FIG. 4.—Wall Lamps.

very highly and carefully finished, and so great attention is given to the lacquering and polishing that no cleaning is required. From among a number of designs we have selected the following:—

Fig. 1 shows an elegant table lamp, carrying a shade of silk of any colour. Of course, it is easy to arrange for the contacts in these table lamps, either by means of flexible

wires, or, if the lamp is ordinarily required in one particular place, by means of a conducting contact through the table.

Fig. 2 shows another design of table lamp, with branching arms for two lamps. It will easily be understood that these various table lamps are designed for various purposes—some for the dining-room table, some for the drawing-room, some for card tables, reading desks, and so on, through the requirements of the house.

Fig. 3 shows a light electrolier for a moderately-sized room. It is generally believed that it is the design of such electroliers which permits the greatest display of artistic taste, though some unbelievers maintain the contrary, and that the greatest difficulty of the designer is met with when he has to design a solitary lamp fitting, and keep the cost down to a minimum. Still, we allow that business men have to consider what pays best, and undoubtedly they have a greater latitude allowed them when making a large electrolier than with the single fitting. It must not be taken that we look upon any of these fittings as costly; they are not, and we are inclined to believe that the cost compared with the cost of gas fittings will always be in favour of the electric light.

Fig. 4 shows two examples of wall fittings, such as might well serve in a bed-room or a smoke-room.

ELECTRICAL TRAMWAY IN HAMBURG.*

BY J. L. HUBER.

Many efforts have been made of late years to adopt electricity for working tramways. Overhead and underground conductors have been, and are still, employed; but the difficulty is to find a substitute for horse-power in the crowded streets of large towns, where overhead conductors are not admissible, and where those laid underground are exposed to a multiplicity of evils only known to those who have endeavoured to cope with them. In this field the storage-battery alone could compete with horse-power, and then only when the energy is stored in a properly controllable form. The author ventures to say that every practical engineer, knowing the conditions which exist in large towns, will agree with him that any vehicle destined principally for the transport of passengers should be, when possible, independent and self-contained in its motive power. It is unadvisable to depend upon an engine located at a distance, a breakdown in which, or defects in the leads, would interrupt the service of the whole line. These views influenced him in choosing the Julien system for introduction into Hamburg. A paper read before the Society of Arts by Captain Douglas Galton, on the 20th of January, 1886, fully describes the Julien system.† The speciality of the system is that accumulators, in which the energy is stored, are used in different groups, which may be placed in parallel or in series, according to the power required. This is accomplished by a special switch under the control of the driver, and without any artificial resistance. Only one electric motor is necessary, the power from which is transmitted by ropes to a counter-shaft, and from this by a pitch-chain to one of the axles.‡ The first car (No. 61) in use at Hamburg is similar to that exhibited at Antwerp in 1885. The weight of this car is, ready for service, 4·83 (metric) tons, of which the accumulators come to 1·2 ton, and the weight of the series-wound motor of Messrs. Siemens Brothers, London, to 572lb. The accumulator battery is placed in eight drawers, with slide contacts; in each drawer there are four boxes, with three cells, and with 15 plates in each cell, consequently there are 96 cells. The whole battery is divided into four parts of 24 cells each; these four parts may be arranged, by simply turning the Julien switch, either (1) all four in parallel, giving a current of $24 \times 2 = 48$ volts tension; or (2) two and two parallel, and then in tension = 96 volts; or (3) two in parallel behind the two others, in tension = 144 volts; and (4) all four in tension = 192 volts. The capacity of each cell is 92 ampere-hours, and consequently the amount of stored up energy is $192 \times 92 = 17,664$ watt-hours. The tram-

way line selected for the trials with the electrical traction extends from the Rathhausmarkt in Hamburg to the Berthastrasse in Barmbeck, and is 5,360 metres (5,862 yds.) long. The steepest incline on the line is 1 in 40 and 100 metres long, but only about 800 metres are level, the remainder being more or less steep inclines with numerous curves. Thus this line, of which the route for nearly two miles lies through crowded streets, presents all the difficulties which tramways have to overcome in large towns, and as the trial has been extended over eight months (May to December, 1886) on a common public road, it may be considered a very fair one. During the whole of the trial the engineer in charge recorded the number of watt hours charged on each battery, to find when it needed re-charging, and the time and length of way which the car had run with the battery before this became necessary. By always putting fully charged batteries into the cars, the amount of watt hours put into the accumulators, to replenish them, after having done a certain service, gave a full account of the work done. It showed the energy required for the work, and the variations between the different loads, or the difference of power required to run the car. Before commencing the regular service, the author made trial trips at night with the car No. 61 from the Berthastrasse to the Rathhausmarkt and back. During these trial trips the car was loaded with iron bars, to represent the full weight with passengers in regular service. The current passed through one of Paterson and Cooper's ampere-meters; the revolutions of the motors were indicated by a tachometer of Buss and Sombart, and the tension of the current was controlled by one of Paterson and Cooper's voltmeters. The weight of the car was, on all the trial trips, 7 tons, of which 4·83 tons represented the weight of the car proper, and the remainder that of 29 passengers, one driver, and one conductor, or 31 persons at 154lb. each. The result was that in running up the main incline 10,700 watts were used—i.e., 54 amperes at 192 volts; further, that on the level 1,800 watts—namely, 19 amperes, multiplied by 96 volts—were required, and that the dynamo made then 900 revolutions. The ratio between the dynamo and the driving-axle was 1 to 10, the diameter of the wheels being 736 millimetres (29in.), and the circumference 91in. Thus, at 900 revolutions of the motor, the speed of the car was—

$$\frac{900 \times 2 \cdot 312}{10} = 208 \cdot 080 \text{ metres,}$$

or about $3\frac{1}{2}$ metres in one second = 12 kilometres (7½ miles) in one hour. The speed allowed for the tramcars is 12 kilometres an hour in the town and 16 kilometres in the suburbs. As the trial trips were made during the night, the author drove the car at a higher speed. As tractive power he calculated 12 kilogrammes for every ton of weight, plus 1 kilogramme for every millimetre of grade per metre, and per 1 metre of speed per second, or—

$$T = \{(t \times 10) + (l \times g)\} s,$$

where T is the tractive power, t the weight in tons of 1,000 kilogrammes, g the grade in millimetres per metre, and s the speed in metres per second. This formula gives very fair results when the rails are in good condition; but to allow for curves, as well as for dirty rails, it is necessary to multiply the values given by the formula by 1·5. The journey from the Berthastrasse to the Rathhausmarkt and back to the Berthastrasse, equal approximately to 11 kilometres (6·8 miles), occupied 55 minutes, and $96,802 + 94,652 = 191,454$ watt-minutes were indicated, or 3,181 watts per minute, or 17,405 watt minutes = 290 watt-hours for every kilometre. As during the trial the accumulators were in first-rate condition, an efficiency of 80 per cent. could be reckoned on, and thus the accumulators required a charge of 362 watt-hours for every kilometre of way made by the car (7,000 kilos) on the line in question.

As stated above, the output of the accumulators was 17,664 watt hours, and thus, in every 290 watt-hours per kilometre, 60 kilometres might be run with one load, but as at any moment something might occur on a tramway, and more power might be required to overcome it, the author did not consider it advisable to allow the accumulator to run so far down; and besides, the life of accumulators is

* Selected Paper, Institute of Civil Engineers' Proceedings.

† Journal of the Society of Arts, vol. xxiv., p. 157.

‡ Elektrische Zeitschrift, Berlin, 1887, p. 222, and Zeitschrift des Vereins Deutscher Ingenieure, 1887, p. 333 and Plate 9.

prolonged when they are never fully discharged. . . . The mean energy expended in volt-amperes to reload the accumulator was:—In July, 392.16; August, 354.72; September, 441.49; October, 417.37; November, 701.92; and December, 561.374. The lowest amount of energy for 1 kilometre employed in one day, when only one car (No. 61) was running, was 280 watt hours, on the 23rd of August; and the highest to the end of October 630 watt-hours. This enormous difference, as well as the daily variations, were due to the state of the rails and the traffic, which were both influenced by the weather. During summer, and in fine weather, the rails are clean, and in Hamburg the streets are well swept and watered; besides, the traffic is small, and the public evenly distributed on both platforms; but if the weather is misty the rails are slippery, the cars more fully occupied, and the passengers avoid the forward platform and crowd on the hind one. This, when the driven axle is foremost, occasions loss of

FIG. 1.—Plan of No. 61 Car.

energy. The worst is when the grooves of the rails are filled with frozen dirt, and this happens in Hamburg when during the night sudden frost sets in, and the cars have to commence running before the salt-car, or before the salt has sufficiently acted; such a day was the 8th of December, when the average energy rose to 890 watt-hours.

Now, with an average of 362 watt-hours per one kilometre, 19 amperes at 96 volts are employed on the level, and 54 amperes at 192 volts on different inclines, so that there must be, when 630 watt-hours are necessary, an expenditure of at least $54 \times 630 = 34020$ watt-hours.

362
that, under bad conditions of the road on the inclines, the power will be still higher than under good conditions, and that a current of over 100 amperes will pass the motor.

An electric current of 94 amperes \times 192 volts is equal to an expenditure of 244 h.p., which had been taken out of the accumulators; but this had not been used only as tractive power, for it had heated the motor and had been wasted, and this is the weak point of all electric tramways. Every locomotive and every self-propelling car is made to do a certain amount of work on a certain line, to propel at a certain speed a limited weight on a maximum of incline that is, at a maximum of resistance of the road, if the weight is constant, and the resistance on the road increased, the speed diminishes, and at last the motor must stand still. In a steam engine the amount of steam, or energy, that might be taken out of the boiler (the accumulator) depends

FIG. 2.—Plan of No. 86 Car.

upon the volume of the cylinders and the number of revolutions. If the engines stand still, no revolutions are made and no steam is taken out of the boilers, and if the safety valves do not blow off steam, no energy is wasted. Quite different are the conditions of the electric motor; the amount of current that flows through the coils of the motor (for tramcars series-wound motors are to be considered) depends upon the number of revolutions of the armature; and, at the same tension of the current, the greater the number of revolutions the less is the amount of current. Thus, when by increased resistance on the road the speed of the vehicle, and consequently of the motor (armature),

diminishes, the amount of current increases, and comes to its maximum, which depends upon the internal resistance of the motor when the motor stands still. Every motor is constructed to run at a certain tension of the current, at a certain speed, and will then take a certain amount of current. If, by overloading the car, or overcharging the motor, the speed diminishes, the amount of current will increase, yet the increase of current will perform very little useful work, but heat the motor. The heat partly disappears by radiation, but is, at all events, a waste of energy, and must be avoided.

The appearance of heat or light where only power is needed is a waste of energy, and consequently a waste of money. Still, this occurs in a great number of electrical installations, and principally electrical tramways; in these installations a series of artificial resistances are employed, and are more or less thrown into the circuit, according to the amount of current that has to pass the motor to attain a certain speed or to start. Then, as in those installations, the tension of the current is constant, the amount of current that flows through the motor depends only upon the resistance in the leads to be overcome. Then resistances do not act only like a throttle-valve, but they get heated, and this heat must be absorbed by radiation by the surrounding air, otherwise they will melt. In experiments made for this purpose, the author has melted glass tubes 15 millimetres (0.59 in.) in diameter and 500 millimetres (19.68 in.) long, which he had surrounded with a spiral of German silver wire 1.2 millimetre (0.05 in.) in diameter, and imbedded in infusorial earth in a porcelain pipe of the same length, and of 25 millimetres (0.98 in.) outside diameter. The spiral was melted and stopped the experiment, which he repeated several times, varying the tension of the current, and therefore the amount of amperes passing, and consequently the time in which the wire melted. These experiments show what amount of heat or energy is wasted by resistances placed in the current, and that it is wasteful to adopt such means to use up less energy in the motor, it would be like employing a brake to regulate a steam engine, instead of cutting off and expanding the steam; the resistances in an electric current will do there, because they are simple, where a small amount of current passes them, or where the loss of energy is negligible. To avoid the resistances, Mr. Julien has grouped the accumulators in parallel or in series, as most convenient, and this constitutes one of the great advantages of using accumulators instead of direct current; then by direct current the tension is always constant, and must be so high as to do the maximum of work required on the line, to ascend inclines, or to run with full load at a certain speed. Where this maximum of work is not required, resistances must be introduced. Since, as above shown, the use of the common resistance spirals is wasteful, the author recommends, instead of them, accumulators, which, when charged by the necessary surplus of energy in the line, will serve to light the train or otherwise, and so avoid the useless waste of energy. Finally, the amount of power required on different parts of the line may vary very much; but as it is not necessary to ascend steep inclines at the maximum of speed, the motor or motors may be arranged in such a way that they can do, at a limited speed, the required maximum of work without getting hot, and to effect this the author proposes the use of two motors instead of one, combined in such a way that one may suffice for the level, or for small inclines, but that the two may be placed in parallel on steep inclines; using, then, the current at half tension, the motors will turn at the lower speed, corresponding at this lower tension, and thus the car will run at lower speed, and require less power to ascend the inclines. The simplest way to arrive at this "relay" for common tram-cars would be to place two armatures on the same shaft in the same, or in two different magnetic fields. But the two motors should not be placed on two different bogies, as in that case a car would always be liable to run off the rails on sharp curves; the forward motor would, on entering a curve, be relatively the weaker one, as it has to overcome more resistance than the one behind, and would be easily thrown by the latter off the rails. This is so well known to railway engineers, that he would not have mentioned it had he not seen an electric car arranged in this way.

After the first car, No. 61, had been in use some time, the author arranged a second car, No. 86, for electrical traction. This car was fitted in a similar way, but the motor was placed between the two axles, and the car had seats for 20 passengers inside; its weight was, ready for service, 6 metric tons, and when loaded with 30 passengers, one driver and one guard, 8.24 tons; the weight of the accumulators was 1.94 ton, and of the motor, 1,188 lb. The motor was by Messrs. Elwell and Parker, and similar to those used on the Blackpool electric tramway. A great advantage of these motors is that instead of using two pairs of brushes, only one pair of contacts is employed to bring the current to the collector of the armature. It is thus possible in running down hill to use the motor as a dynamo, driven by the mechanical energy developed, and charge the accumulators. But further, the motor itself serves as a powerful brake, and he has so employed it many times, when it is necessary suddenly to bring the car nearly to a standstill to avert damage or accident. The final result of his trials is that to drive a tramcar on a line, for every 220 lb. of weight and 1,000 metres (1,093 yards) of way, 7.8 watt-hours are required.

M. D'ARSONVAL ON DANGEROUS CURRENTS.

It may be interesting to give the following abstract of a paper presented by M. D'Arsonval to the Academy of Sciences relating to experiments with various generators of electricity. He used (1) a Holtz machine to charge a Leyden jar; (2) a battery with E.M.F. of 420 volts; (3) a Gramme direct-current machine; (4) Gramme alternate-current machine; and (5) induction coils. Electricity is stated to produce death in two ways (a) directly by injury to the tissues; (b) indirectly by action on the nerves. In the former case life is beyond recall, in the latter, it is in most cases possible to bring the individual back to life by artificial respiration instantly resorted to. A static discharge is not absolutely mortal, unless the "medulla oblongata" be struck by a localised discharge, the energy of which exceeds 22 foot-pounds. In that case the tissues are destroyed. With weaker discharges, the effect is due to excitement of the nervous centres, or, more tardily, to secondary results of injury. It is much less easy than is generally believed to kill an animal outright by a discharge of frictional electricity. M. d'Arsonval concludes that the duration of discharge is of the greatest importance; and, in alternating currents, the frequency of alternation. In the general case of accident death occurs through reflex action, and mostly through arrested respiration; and the practical conclusion is that in every case artificial respiration should be instantly resorted to.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.*

BY W. H. PREECE, F.R.S.

I have taken a great deal of pains to verify the dimensions of the currents as detailed in my paper read on December 22nd, 1887, required to fuse different wires of such thicknesses that the law

$$t = a d^2$$

is strictly followed; and I submit the following as the final values of the constant "a" for the different metals:—

	Inches.	Centimetres.	Millimetres.
Copper	10.244	2.530	88.0
Aluminium	7.585	1.873	59.2
Platinum	5.172	1.271	40.4
German silver	5.230	1.292	40.8
Platinoid	4.750	1.173	37.1
Iron	3.148	.777 4	24.6
Tin	1.642	.405 5	12.9
Alloy (lead and tin 2 to 1)	1.318	.325 5	10.3
Lead	1.379	.340 6	10.8

With these constants I have calculated the two following tables, which I hope will be found of some use and value:—

* Read before the Royal Society on April 19th, 1888.

TABLE SHOWING THE CURRENT IN AMPERES REQUIRED TO FUSE WIRES OF VARIOUS SIZES AND MATERIALS.

CORRESPONDENCE.

NOMS DES PLUME.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR.—I had not the pleasure of hearing Mr. Preece's recent paper read at the Society of Telegraph-Engineers—(are we not the Institute of Electrical Engineers yet?)—but I should like to say a few words upon a portion of your leader bearing thereon. If Mr. Preece proposed to taboo *noms des plume*, in my humble opinion he was quite right. I will not go so far as to say that there are no cases where a man would be justified in writing over a *nom de plume*, but I think they are very few and very far between.

In the vast majority of cases, the fact that the writer could not, or would not, allow his name to appear, should be sufficient reason for not writing.

Mere shyness at seeing one's name in print soon wears off, but, on the other hand, the cover of the *nom de plume* is too often used for violent personal attacks and slipshod work. It does not matter, no one will know who wrote it. Even with men who are not given to journalistic discourtesies, the responsibility attaching to the publication of the name of the author, whether of article or letter, must have a sobering effect. It has the same effect that, in my opinion, tones down the bitterness of many a wordy battle.

I would say, also, that articles should be signed, as well as letters. You are quite right in your remarks as to the

education afforded by the technical press. It supplements one's own experience by the thoughts or observations of other men; but if its lessons are anonymous, they lose half their power. One curious result, too, that is not infrequent should make users of *noms des plume* careful—viz., it sometimes happens that two writers of totally opposite views take the same name.

Let each writer have the courage of his opinions; or, if he fears to exhibit them to the world under their true parentage, not exhibit them at all.—Yours, &c.,

SYDNEY F. WALKER.

May 19, 1888.

[The difficulty of signing one's name does not arise in many cases such as those that would probably come under our correspondent's observation, nor, indeed, in many cases where pure, or even applied, science is concerned. Adverse criticism, however, does bring down considerable vituperation upon the head of the critic, and would undoubtedly, at times, subject him to personal insult. A case to the point arises out of the very issue in which we more or less jokingly opposed Mr. Preece. The remarks in the next article were somewhat adverse to a report upon a tramway system, and these, or some other remarks which we fail to recognise, have brought to us some choice "Billingsgate." A copy of the paper with "unsigned" comments, personal and otherwise, scattered over its pages, has been returned to us, postage paid. The writer of these comments evidently has not the courage of his opinions, otherwise the result would have been, had it occurred a century ago,

"pistols for two, coffee for one"—occurring now would lead to avoidance of personal contact as derogatory to any respectable person's reputation.—ED. E. E.]

WIND MOTORS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I am interested in wind motors, and the article in your last suggests the following questions:—

The writer asserts that wind motors are economical, but will he give a reason why they are surely and rapidly being superseded for grinding corn in England and elsewhere. Is wind less constant here than in America? Wind mills are almost valueless in this country, as owners have found to their cost.

Now that steam can be generated so cheaply and is always at command, will any one rely upon so fickle or so expensive (for repairs) power as the wind.—Yours, &c.,

WIND MOTOR.

Colchester, May 19th, 1888.

TAVENER'S COULOMB METER.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Observing in the current issue of your journal a notice of an electrical meter, said to be of Prof. Elihu Thomson's design, I think that attention should be called to the fact that the principle upon which this meter works has already been adopted by Tavenor in his meter. The principle involved is that of utilising the heating property of the current for producing an oscillating motion of the containing tube, and consequent registration of the quantity of electricity, whether by continuous or alternating currents, passing through the circuit.

As Prof. Thomson's meter has been designed on exactly similar lines as Tavenor's, and, moreover, bears upon it evidence of a knowledge of the prior existence of Tavenor's meter, it appears to me that to the last named individual is due the credit for the ingenuity manifested in the production of a meter working on a principle so different from those upon which current-meters have hitherto been designed and worked.

Honour to whom honour is due. To originate a meter working on the principle I have described, which shall register accurately the exact amount of current passing through it at any time, is one thing, but to copy such a meter and appropriate its invention is quite another.—Yours, &c.,

WM. PHILLIPS MENDHAM.

Western Electrical Works, Bristol, May 22nd, 1888.

JARMAN'S ELECTRIC TRAM-CAR.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I notice that you have printed Messrs. E. Walker and Hyde's report upon my electric tram car. So far so good. If you had allowed your readers to have drawn their own opinions, I should not have troubled you with a word of reply, but your remarks thereon, "to my mind," are so unbecoming that I must state what I think upon them. You there state that "one section of the reading public, etc., looks to the technical press for guidance." This I will venture to say they never do. The investing public look to that which will bring a good return for their money, and in this particular the technical press is completely impotent, especially in matters electrical. The opinions of high scientific authorities upon the Faure accumulator, etc., etc., a few years since, taught the public generally what value to put upon such. You further state that "Reports of the kind we notice are obtained only with the ulterior object either to get money upon patents, or to promote a company." Now I will, like you, stake my reputation upon the fact that this statement is absolutely false, and that you are not warranted in making such a statement, because you cannot support one word of it by facts. The truth is, the whole of the working out of this car has been borne by private enterprise for a year and a half. Neither the public nor anyone else have ever been asked to bear a single penny of the expense. Now that the car bears out such favourable results, and considering that before long one of

the suburban tram lines will be worked entirely by these cars, goes a long way to prove the unsoundness of your surmise.

I nevertheless adhere firmly to the plan of duplicating the armatures, for reasons which you, apparently, up to the present do not seem to grasp. I think your remarks also ought to be taken, as, you state, about Prof. Short's paper, *cum grano salis*, very much so, as you appear to advocate a certain make of motor, as though other makers would not gladly undertake the same.

It would be very interesting to know of the number of armatures that have been burned out in tram-car experiments where the single armature alone has been employed, this latter defect having led me to construct the present form of motor; and I will further state that, until practice proves my plan to be wrong, I shall firmly adhere to it, considering, as I do, that an ounce of practice is worth infinitely more than any number of unsupported editorial remarks.—Yours, &c.,

A. J. JARMAN.

Brixton, S.W., May 23rd, 1888.

[We are glad to find that Mr. Jarman has the courage of his opinions. As we differ entirely upon almost every point touched upon by his letter, and as time alone is required to prove which of the twain is correct, there is little good to be gained by controversy. It may be remarked, however, that time has already shown the technical press to be a powerful factor in the question of electrical investment. Undoubtedly, it does not, and it cannot, stem the torrent when madness seizes the political press; but, in ordinary times, company-mongers electrical are not certain to have their own way when the technical press is against them. We welcome, also, with considerable pleasure, the statement that Mr. Jarman's system has been financed privately, and trust we may find that it will continue to be so financed. If it is as good a thing as its author declares, those who trust it will reap their reward. If it turns out badly, they will have the consolation to know they did not lead maids, wives, and widows astray in their investments. *Nous verrons*.—ED. E. E.]

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—The report on Jarman's electric tramcar, published in your issue of last week, is, as pointed out in your leader, very unsatisfactory and incomplete. Some four or five years ago Mr. Reckenzaun showed that a tramcar might be propelled along a track by means of a motor and accumulators, and what beyond this can be deduced from the figures furnished in the report? The two most important items—the cost of haulage per car mile and the proportion of dead weight to passenger weight—are conspicuous by their absence. If these were furnished, together with some idea as to how often the battery-plates must be renewed, the report might then be perused with some interest. After what we have seen at Brussels, and still more recently at Stratford, it would be very surprising—even were a charging station for a large number of cars laid down—if "there were a distinct saving per car mile over the present cost of maintaining a number of horses to perform the same work," or, indeed, if the figure came out anywhere under 9d. per car mile. From what I have seen of electric tramway work the duplicating of the motor seems to me wholly unnecessary and absurd, and the report itself points to the same conclusion, for on the "return journey" we see that car mounted a gradient of one in twenty, and a little lower down we find "both armatures were perfectly cool." Now, if the motor started and dragged this heavy load up a gradient of one in twenty, and then was perfectly cool, it is quite certain that the heating of its armature will never be such as to cause the slightest inconvenience.

Whatever the purpose served by the report, there is no disguising the fact that the repeated trials and failures of the accumulator cars are having a bad effect on the public, and will cause the various tramway companies to view with apprehension and distrust all further attempts at electrical traction, whether employing accumulators or worked on the direct system, which to many seems to give more promise for the future.—Yours, &c.,

F. C. ALLSOP.

THE ELECTRICAL ENGINEER.

Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at **THREE WORDS for ONE PENNY**, with a **MINIMUM** charge of **SIXPENCE**.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

ANSWER TO CORRESPONDENT.

W. D.—Your letter has been partly answered by post, but as others may desire information concerning the opening for electrical engineers, we give a greater publicity to that portion of the answer. There is far too general an idea that electrical engineering is a genteel profession, and that a man can get on well in it without soiling his hands. This is a mistake. Electrical engineering is but a branch of mechanical engineering, and the best men are those who have an electrical training superposed upon a mechanical training. Roughly speaking, the openings into the profession may be classified under four heads. In addition there are the directors, managers, and the clerical staff, in all of which a commercial rather than a technical training is requisite. We might have also included the estimating department. Take first the designing and the drawing offices. Whatever can be said as to the technical requirements of designers and draughtsmen of other machines can be said with as great force in electrical work. Secondly, we have the testing department. It is here that the highest technical training tells. The number, however, of vacancies is certainly limited, and when vacant are filled by the best men available. Next we have the artisans—really mechanical engineers—who construct the machines. Then, lastly, we come to those who carry out installation work. These men have diverse duties. Many are merely linemen, earning little more than labourer's wage. Many are labourers purely and simply. Still every installation requires at least one or two men who have a fairly high training. These men are in charge and should have a good technical training, both as regards mechanical and electrical engineering. Just as an engine driver is expected to be able to carry out any little ordinary repair to keep his engine in working order, so the man in charge should be able to do, or direct how to be done, any little operation required to keep the installation thoroughly efficient. We look upon this class of the profession as having in their hands the making or the marring of the future of electrical engineering. The man who knows a lot about curves and formulae, and book-learning generally, is not worth a dump if he cannot handle a hammer, screwdriver, or soldering iron, and is afraid to tackle any difficulty out of which he cannot see his way with mathematical accuracy. The would-be worker must, therefore, decide into which of these divisions he wants to gravitate and educate himself accordingly.

CONTROL AND REGULATION.

General Webber, during the discussion on Mr. Crompton's paper last week at the Society of Arts, forcibly directed attention to a subject which has not received the consideration it ought. He pointed out that at the present time the electric lighting industry has to contend both against control on the one hand and no control on the other. A company or a firm obtaining a provisional order rests under the disability of being compelled to carry its wires underground, while, on the other hand, the company that ignores provisional orders and desires "to carry electricity to the most profitable points, just as the bee goes from flower to flower in which there is most honey," can and does place the wires overhead without any control whatever. Parliament, General Webber contended, did not intend that the industry should be crippled in an unforeseen way of that kind, and the sooner these overhead wires were controlled the better.

The facts of the case are exceedingly simple. Anybody who likes can put wires overhead for any purpose whatsoever, provided permission is obtained from the householder to erect supports. The wires are not restricted to telegraphy or to telephony, nor is it necessary that the one should be above the other; all may be mixed in the manner best calculated to bring about accidents. It is only when a contractor says he intends to satisfactorily provide for a general demand that control comes in, and then he is completely controlled out of existence. Ours is a wonderful nation—wonderfully governed. Good, sound, practical, common sense legislation is so con-

spicuous that it is only recognised by its absence. A telephone company is permitted to do as it pleases, while the electric light company has to comply with the regulations. Both are formed to supply certain wants of civilisation, and both desire to make money for their shareholders. The want supplied by the one is more of a necessity than that supplied by the other, and yet the latter is preferred to the former. Thus it is that those engaged in electric lighting hardly rest easy in their position. Our friends of the gas industry say we clamour too loudly, and yet we only ask that an injustice may be rectified. Generosity is not to be expected in business matters, and especially when competitors are concerned, but it might be well that justice and nothing but justice should be allowed.

The following evening, in his reply at the Society of Telegraph-Engineers, Mr. Crompton mentioned another "regulation" urgently needed, if electric lighting is to increase and multiply. It was the regulation of the various pipes carried under the streets and pathways of this huge metropolis. It seems also that the crowns of the cellars are not all the same distance under the path, and that in some cases there is barely two inches of clearance. There can hardly be any valid reason why the crowns of the cellars should not all be regulated, and not allowed within one foot of the ordinary level of the pathway. The pipes from the gas and water mains into the houses should be placed at regular distances below the surface, then any workman taking up the pathway or street would know where to expect to meet these pipes. Less damage would be done than now, when any blow with the pick may come into contact with a pipe at any distance below the surface. We have always contended that the true solution of the whole problem was in the compulsory construction of subways under every new street laid out. The local authority, upon whom the first cost of construction fell, would charge a moderate sum to users sufficient to repay the initial cost within a term of years, say twenty-five, to provide besides the sinking fund, the annual interest, and a surplus sufficient to keep the subway in efficient repair. The uses to which such a subway could be put are manifold. The gas and water pipes, the telegraph, telephone and electric light wires, would all find a suitable home therein. Difficulties, no doubt, would arise as regards induction, insulation, leakage, &c., but these are not insurmountable and would be overcome. Unfortunately, this devoutly to be wished for consummation is not likely to be carried out by this generation. It is the ideal to which we constantly look. The cost of such a system to the users would, at any rate, not be more than the cost of the present system, when one day the gas company takes up and puts down the roadway, and a week later the water company does similarly. In the course of a

few years the money spent in doing this work would build the finest subway ever constructed: and yet we wait for it in vain.

TRACTION.

An American contemporary, seeing the strides electricity was taking for traction purposes on tramways, has set about collecting the opinions of the leading men upon the question of the best mode of traction. The replies are various; nor is there any great preponderance of opinion in any one particular direction. The horse has its advocates, so has steam, while supporters are found for electricity, either supplied direct or by means of accumulators. The President of the Chicago City Railway says: "When an electric motor will draw trains of three or four cars, carrying two hundred people at intervals of forty seconds, for fifteen hours in the day, year in and year out, starting from the very heart of the city and ending away out in the country, in heat or cold, wet or dry, snow or dust, for eleven and one-third cents per car per mile, at the rate of ten to fourteen miles an hour, then, and not till then, can it even claim to approach the cable system as a motive power." The President of the Dallas and Oak Railway says: "I think it will be many generations before steam will be surpassed as a motive power"; while the President of the Oakland Railway inclines to storage batteries, as does the President of the Concord Company. In most cases the opinion given is in favour of that system with which the writer is most interested, though this is not always the case, and we are glad to see some consideration shown towards the living motor, the horse. It is so well known that the strain upon these animals is so great when used for tramway or omnibus work, that they depreciate in value very rapidly. Depend upon it, the animals would not choose that particular class of work if they had any voice in the matter; but although civilisation talks largely about its sensitiveness against cruelty, very little has been done to put a stop to such cruelty. Why not say what is really meant—that the only question which usually arises is that connected with *£. s. d.*? Unless electric traction, all things considered, becomes cheaper than horse flesh, it will not be used.

THE TESLA SYSTEM OF DISTRIBUTION AND ELECTRIC MOTORS FOR ALTERNATING CURRENTS.

Six patents, says the *Electrical Review* of New York, were issued last week under date of May 1st to Nikola Tesla, involving the various features of his very remarkable system of distribution and transmission of power by alternating currents, which are at the same time adapted for the production of light. The system is based upon a novel principle, which is very clearly set forth in the claim of one of the patents—namely, producing a continuously progressive rotation of the polarities of either or both elements (the

armature or field magnet or magnet) of a motor, by developing alternating currents in independent circuits, including the magnetising coils of either or both elements; and as a modification of this, shifting the poles of one element by alternating currents while magnetising the other element by direct or continuous current.

One of the most interesting forms shows a generator of alternating currents whose armature contains two independent circuits of varying phase, and these two circuits are connected with the field magnet coils of the motor in such manner that the alternating impulses in these two circuits will produce a continuous rotary shifting of the poles of the field-magnet and communicate a rotary effort to the armature, which in itself is a body of iron with coils of wire, whose circuit is entirely closed. That is, there is no communication whatever of the armature circuit with any other

FIG. 1.

circuit, and consequently there is no commutator, collector, or brushes of any kind carried by the armature. It will thus be seen that there is here developed a curious and interesting phase in the construction and operation of electric motors, and one which is entirely novel, in that there is no portion of the entire motor subject to wear and tear in even the slightest degree, except the shaft and its bearings. The direct consequence of this in the commercial use of motors is of great importance, as the attendant having charge of an electric motor of this character would have no more responsibility than he would have in looking after the lubrication of a counter-shaft.

FIG. 2.

Another interesting feature is the result of perfect synchronism between the motor and generator which arises from the peculiar principle of operation of the motor, and the latter can be constructed to run at a predetermined speed provided the speed of the generator and that of the motor have a common divisor. The practical result of this is perfectly constant speed in the motor with constant potential supply, no matter how much the load may vary on the motor. The motor when running at its highest attainable speed reverses almost instantaneously, on a reversal of the line connections, so that the simple motion of the switch effects the instantaneous reversal of the direction, and the time occupied in changing from

highest speed in one direction to highest speed in the opposite direction is but a fraction of a second. The rotary effort of the armature is very great, and there is no difficulty whatever attendant upon the starting of the motor under load. The efficiency is extremely high, and can be increased to the highest possible extent attainable by continuous current motors.

The system also takes with it the novel construction and operation of transformers, a simple form of which is illustrated by Fig. 2, which shows a closed magnetic circuit wound with four primary coils which are connected into two high-tension circuits in such manner as to produce two consequent poles at opposite ends of a diameter, and these by the action of the generated current in the high-tension circuits progressively shifting around the magnetic circuit, carrying the consequent poles continuously around; in other words, the two consequent poles rotate continuously, the winding, of course, remaining stationary. The secondary coils are wound on the primaries, and can be connected among themselves in any desired manner, according to the work to be performed.

It will be observed, therefore, that the action of the alternating currents is not to reverse polarities of the core, but to simply rotate them by the peculiar action of the current impulses in the two primary circuits, and it seems to follow, as a matter of course, that there is less energy wasted in the conversion than occurs in the ordinary converter, where the magnetic poles are alternately reversed. Instead of using four wires from the generator three can be used, and one of the three forming a common return for the other two.

Altogether, Mr. Tesla is to be congratulated, not alone on having produced something entirely novel in the electrical world, but also for having made thoroughly practicable the utilisation of alternate currents for the transmission of power. The motors for a given output of mechanical energy are extremely small, and are, as stated, absolutely self-regulating, and there is no electrical element of wear and tear connected with them in any manner whatever, and this feature alone of the closed circuit armature without external connections stamps the series of inventions as being something entirely new and original, and it looks as though the new principle would have great influence on the application of alternating currents to practical forms of electric motors, and we congratulate Mr. Tesla upon his success in this direction.

THE RELATION OF ELECTRIC LIGHTING TO FIRE INSURANCE.*

BY S. E. BARTON.

In considering the relation between electric light and fire insurance interests, I must confine myself mainly to the situation in New England, because I am familiar with what has been and is now being done there, and I am quite as unfamiliar, except in a general way, with the relations that exist between the two interests outside of that small but lively quarter of our country.

In order that you who live away from New England may better understand what I may say as I proceed, it will be well for me to tell you briefly what kind of an insurance organisation we have there.

The New England Insurance Exchange, which exercises a modest control over a part of the fire insurance matters within that territory, with the exception of the city of Boston and State of New Hampshire, is a body composed of the special agents, adjusters, travelling men, or so-called field men, representing the various stock fire insurance companies doing business there—some 150 in number. These men mostly have their headquarters in Boston, which is verily a "Hub" in that respect. They are constantly skirmishing over the territory, individually or in squads of two or more, adjusting losses, and occasionally, through the co-operation of their local agents in the towns and cities, stealing good risks from each other or from some other competitor; but every Saturday finds a large majority of them back in Boston, where they con-

* Paper read before the Pittsburgh Electric Light Convention.

vene in regular session, and consider with legislative dignity any matters of common interest, electric lights included. They swap experiences, swap yarns, swap anything for something better; consequently they are a body of wonderful unanimity in any cause that promises common good to themselves, and justice and fairness to others. They say to electric lights, "Burn, after our inspector has approved the manner in which you are installed and maintained"; and as a consequence there are in New England to-day, not including Boston and New Hampshire, 13,344 arc and 157,845 incandescent lamps radiating their beautiful bright light where the feeble flicker of the gas jet and kerosene lamp could not penetrate.

So concerted is the action of these men, that were they, by reason of any necessity, compelled to say that electric lights shall not burn, comparative darkness would once more reign supreme in that fair land; but while they can continue to count upon their fingers the yearly fires caused by this modern illuminant, I think I can safely assure you that their dreaded power of extinguishment will not be exercised.

I have made exceptions of the city of Boston and the State of New Hampshire, the reasons for which are these:—The former, in its fire insurance matters, is supervised by a similar organisation to ours, known as the Boston Underwriters' Union, which handles electric lights in the same manner as our exchange. The latter, through antagonistic and unfair legislation, over two years ago caused the absolute retirement from that State of every outside stock fire insurance company, and they now manage that business by themselves. By what light they work we know not; but, judging from their sad experience of the past year, we are led to believe that they work by the unholy light of their own wicked ways.

I have described the character of our exchange principally to show the difference between it and most of the insurance organizations of our country, which are generally composed of officers of companies, or local and general agents in the large cities, between whom, by reason of their greater competitive relations, there exists a less cordial and familiar fellowship; and they are consequently less able to harmoniously and successfully devise and carry out methods of improvement and mutual good.

In the first year of our existence, some five years ago, we realised, after having paid considerable sums for losses caused by electric lights, that our interests demanded the inspection of all such apparatus by some person selected by ourselves, if we were to continue granting permits for the lights without charge. We were a year or two, in a sort of experimental way, in getting settled down to a perfect system of inspection; but the result of the two years immediately preceding 1887 showed us, for the labour we had undertaken, a loss of less than 8,000dols. from electric lighting in our territory. We had by that time not only given up all thought of making an extra charge for a permit to use your lights, as we do in many cases for kerosene oil, and in some instances for gas, but we were fast beginning to show our preference for your illumination by granting reductions in our rates of premium. The year 1887 has shown us a loss record from your lights something less than any previous year, notwithstanding the great increase in your installations; and the spirit of recognition of your superiority in point of safety has steadily gained ground, until I am happy to predict that before another month has passed the New England Insurance Exchange will have announced its favour in the form of a schedule of reduced rates, which it purposes to make on certain classes of risks where the exclusive use of electric lights is guaranteed. I think in this respect we will have fairly taken the lead.

A proposition to this end was made by the electric light committee of our exchange a year ago; but while we had for two years previous made an occasional reduction in rates, and have done so more generally during the past year, the time has not seemed ripe until now for an open announcement to that effect.

This feeling of preference for electric lights has been very gradual in gaining ground with us, and has reached a general recognition from the fact that the fires from that source have been few in number, and the losses small in amount;

and this favourable result has most assuredly been due to our perfect system of inspection. In this claim I am supported by the greatly increased number of fires that are reported as occurring in sections where insurance inspection does not prevail.

That there are in your method of lighting many inherent possibilities of causing combustion and loss of property thereby, I need not claim, because none of you would for a moment deny it; but what I do want to claim, and mean to persist in maintaining, is, that there is no reasonable excuse for any fire to be caused by your apparatus, except in very rare cases, where some unexpected and unavoidable accident may occur.

It is quite possible for you to reduce the fire hazard of your system to the very lowest degree.

It is quite as impossible to do so with any other means of artificial lighting. How can any care or control be exercised over the promiscuous use of kerosene lamps while men, women, and children, including the careless, the thoughtless, the stupid, the old and feeble, the young and weak, are handling them? What can prevent the innocent but agile cat from upsetting the lamp carelessly left in its path, as it is not unfrequently accused of doing. Surely no insurance inspector, even with his ubiquitous habits, could prevent such catastrophes.

While greater care and a system of inspection could prevent some of the many explosions in the gas system, they could not prevent combustible material from coming in contact with the open flame, neither in the dwelling, the store, nor the workshop; nor could they prevent an occasional escape of gas through a leak, or a burner carelessly left open; and in that event no amount of cautionary rules could deter the innocent occupants of the premises from going in search of the leak with an open light in their hands.

While our policies distinctly exclude damage caused by explosion unless fire ensues, and then only cover the damage caused by fire, there is usually fire enough ensuing to "ring us in"; and the drawing of the line between the explosion and the fire is usually disastrous to us.

Therefore I hold that, while no possible human foresight can prevent fires from the old methods of lighting, it is not only possible, but quite an easy matter to prevent them in your case if you set about it rightly.

If I were to presume to offer advice in the matter, it would be this: Where insurance inspection is already being practised, combine among yourselves and support it by paying whatever is reasonable for carrying on the work in an intelligent and economical manner; also by helping them improve their rules and requirements from time to time, as your experience develops new means of safety.

Where such work is not being performed, get together in the same manner, those of you who are operating in that field, and ask the insurance men to appoint an inspector; then submit your work to him, conform cheerfully to his reasonable requirements, and go to the public with his approval. The approval by insurance companies of any lighting, heating, or power device is necessary. The public wants light, heat, and power; but it must have insurance, for on that the great commercial fabric of to-day depends for solidity.

By such inspection you will bring the fire hazard down to a minimum; you will largely increase the growing confidence of the public in your lights; you will rapidly clear away any lingering prejudice with insurance men against you; and, in place of opposition that you may now occasionally meet with from them, you will readily obtain their fullest indorsement—more than that, even, you will doubtless receive positive encouragement from them in the way of concessions in rates in many cases.

The two interests should harmonise and work together to the greatest degree. You have in your system of artificial lighting great possibilities of reducing the enormous fire waste considerably; while we have, through our endorsement and encouragement, the power to largely increase your development; and the two together can give mankind more light and better light, and they need it.

I do not hold that you are deficient in any degree as to what does and what does not ensure safety in your work, but I think you will agree that in the construction and

maintenance of your equipments you are sometimes obliged to depend upon those who are not so proficient in their calling as they might be. The good insurance inspector, who gleans his knowledge and experience from all, helps you to educate and improve in usefulness these employees to whom you trust your work. I refer particularly to the construction and dynamo men and the trimmer, and to the latter more particularly. If this functionary had possessed a knowledge of the possibilities of fire from the arc lamp, the losses from electric lighting in New England last year would have been too inconsiderable to mention.

Right here I wish to speak of a habit that sometimes possesses local companies that of hiring inexperienced help because it is cheap. It is false economy, I think.

Competition, which is very great among you, drives you in some cases to lowering the standard of your material and work. It compels you to figure in every possible way to get the job. Nine out of you may be honestly inclined to maintain the highest degree of perfection, but the tenth one outbids you all by figuring for cheap work. Careful and conscientious insurance inspection brings him up to the mark, or shuts him out; and we all profit thereby.

The question of insulation was referred to in a pointed and timely manner by our friend Haskins a year ago, and his suggestions seem to have taken root in the East. Insulated wire is the rule, rather than the exception, in those places where insulation is most needed, and painted wire has "lost its grip." The difference in cost is too slight, and in point of efficiency and economy too great, to allow the reform to languish.

The location of central stations seems to be receiving merited attention, but not to that extent which the good of the profession demands. In the past the practice has been to secure power, especially in the smaller places, where it could be had the cheapest, without regard to permanency and surroundings. The result has been that you have gone into cramped quarters, with hazardous occupations on all sides above and below you. You have got power by using boilers already being worked well up to the limit of safety, or you have set other boilers in the limited space at your disposal. There have been fires and losses charged to you which you might have escaped by locating more wisely; and, as a consequence, too many insurance men now look upon the electric light station as one of the specially hazardous risks.

Locate by yourselves as much as possible. Build after modern fashions. Do not spare brick walls and cement floors where they will add to your safety, and then you will get lower rates from stock fire insurance companies, or our "Mutual" friend Woodbury will provide for you.

There are in New England, as many of you are aware, a dozen or more good, strong mutual fire insurance companies known as the "Manufacturers' Mutuals." They confine their acceptances of risks to the largest and best manufacturing properties in New England and the Middle States, and to a limited extent in the Southern States and Dominion of Canada. Mr. C. J. H. Woodbury is one of the vice-presidents of the largest of these mutual companies, and the recognized expert authority for them all. About five hundred of the large manufactories insured by them are lighted by electricity, either arc or incandescent, and very largely isolated plants. They have received the inspection of Mr. Woodbury, and the greater part of those in New England that of Inspector Brophy also. I take pleasure in quoting from a letter on the subject just received by me from Mr. Woodbury. He says:—

"When electric lighting was first introduced it was the cause of a great many fires, there being twenty-three fires from this source in the sixty one mills using it in 1881 and 1882. By April, 1882, all the electric lighting plants in property which was insured by the Mutuals had been changed to conform to the rules for installation which I had prepared in December of the previous year, and since that time we have not had a single fire from electric illumination. I do not know of any fires caused by electric lights which did not owe their origin to a disregard of principles laid down in those rules as essentially for safety."

I think that statement bears me out in my assumption as to the almost entire immunity from fires due to artificial

lighting that is attainable by the use of your methods, and I ask no better support.

Mr. Dillon has advanced some excellent ideas looking to better work in point of safety in construction and maintenance—that of examination for fitness and qualification of the men who do this work, and the granting of certificates to them if found competent, the same as is done in the case of steam engineers. He would have the board of examiners composed of electrical and insurance experts. My only criticism is that his ideas fall short of the whole necessities. The absolutely impartial inspector is still needed to see that the "tenth man" of whom I have previously spoken does not prosecute his nefarious work without a certificate; also to see that those who hold certificates are not entrusting their work to cheap men who don't hold them, or that the guileless trimmer is not falling into the habit of leaving the bottom off his arc lamps.

I would not occupy your time with technical suggestions if, indeed, I had any to offer because they had better be left to printed rules and inspectors; but it may interest you to know to what extent your business has prospered in New England. The following figures are taken from our inspection records, and are probably about right, they are inclusive of Boston, but exclusive of New Hampshire. For comparative purposes, I give them as they stood at the beginning of 1886 and also 1888.

Number of Arc Light Central Stations.

	1886.	1888.
In Massachusetts	26 ..	45
Rhode Island	5 ..	8
Connecticut	9 ..	21
Maine	4 ..	14
Vermont	none ..	5
Totals	44	93
Increase, 1888 over 1886, 111 per cent.		

Capacity of above in Arc Lamps.

	1886.	1888.
In Massachusetts (including 2,168 in Boston in 1886, and 2,475 in 1888) ..	3,693 ..	7,305
Rhode Island ..	831 ..	1,961
Connecticut ..	782 ..	3,311
Maine ..	520 ..	1,465
Vermont ..	none ..	415
Totals ..	5,826	14,457
Increase, 1888 over 1886, 148 per cent.		

Number of Incandescent Lamps from Central Stations.

	1886.	1888.
In Massachusetts (including 9,000 in Boston in 1888) ..	8,600 ..	74,500
Rhode Island ..	600 ..	2,200
Connecticut ..	none ..	11,050
Maine ..	400 ..	8,100
Vermont ..	none ..	1,400
Totals ..	9,600	97,250
Increase, 1888 over 1886, 913 per cent.		

Number of Arc Lamps in Isolated Plants.

	1886.	1888.
In Massachusetts ..	459 ..	721

Those of you who may know the ratio of increase in other sections of the country for the corresponding period, can judge if New England insurance supervision is a detriment to your business or otherwise.

A whole year without any considerable fire loss in our

country from electric lighting would be a splendid record, but none too good for any of us to contemplate. While such a result is far outside the bounds of probability in the present condition of things, it is well inside the bounds of possibility. As well might we hope to revolve the earth from east to west as to hope for anything short of millions of dollars of fire loss annually from the old methods of illuminating by combustion—the candle, the gas, and the kerosene oil flame, and the accompanying friction match.

THE BRITANNIA COMPANY'S LATHES.

FIG. 1.—Britannia Co's Self-Acting, Sliding and Screw-Cutting Lathe.

FIG. 2.—Milling Apparatus.

FIG. 3.—Milling Apparatus.

Colchester is the home of two or three firms whose names are becoming household words among electrical engineers. Messrs. Davey, Paxman, and Co. of course take the first place. Prof. Forbes and others, in the discussion on Mr. Crompton's paper, pointed out that some of the American makers reduced the number of types of machines they constructed, and made the parts interchangeable. This means a good deal of lathe work; and we now call attention to the Britannia Company, of Colchester, which company is making a speciality of lathes. We herewith illustrate (Fig. 1) a very useful form of lathe, made of the best materials, and fitted with all the improvements practice has found necessary. An illustration of this kind practically explains itself. The company is also introducing the Greatorex patent milling machine, illustrated in Figs. 2

and 3. This apparatus is fixed on the lathe bed at a convenient distance from the headstock, the cutter being already in its place, and a suitable chuck used. Full instructions are given with the apparatus. The cutter can be replaced by a drill when drilling is required.

FORMULAS FOR WIRING.

BY ELMER E. E. EMMONS.

Mr. Crockett's diagram for incandescent wiring [reproduced last week from the *Electrical World*], although good in its way, and saving a large amount of work in calculating, is only a partial solution of the problem. The diagram, as it was remarked in an editorial of the same issue, is only

useful under certain conditions viz., in systems of two or three wires, having the potential and current given with the diagram; for all others it is useless.

Every central station should have diagrams for each system it uses, each diagram to be used only on that system for which it is constructed.

If such a diagram is properly made, and the men instructed in its use, it will be the means of saving considerable time and securing accuracy.

But in the general application of electricity, the factors, current, and potential, are variable to such an extent that it would be impossible to have a diagram to meet all wants. To men having to do wiring, such a variety of conditions are sure to present themselves; and what is really needed is a formula that will fit any case, be it lamps or motors to be supplied, it being immaterial whether the current is taken from dynamo or battery.

I find that most men who have had no experience in mathematics beyond the common arithmetic have a holy horror of anything that resembles an algebraical formula, and, however simple, pass it quickly by.

Now, an algebraic formula is only a rule concisely stated—an idea which they entirely fail to grasp. The same men would read a rule in arithmetic and do an example by it; but when that same rule is presented in the shape of a combination of letters, they immediately turn their backs to it. Any man having a common school education can readily work out any formula that may be given for wiring, and, if he knows the reasons for its structure, will the more readily comprehend and use the same. Such a formula can easily be deduced from Ohm's law, may easily be committed to memory, and will be found invaluable, not only in determining the size of the wire, but in finding the percentage of loss in that already in place.

Ohm's law reads thus: $C = \frac{E}{R}$; that is, the current flow-

ing in any circuit is equal to the electromotive force of the battery or dynamo divided by the resistance of the whole circuit, i.e., of the battery or dynamo and outside circuit combined.

Now, the E.M.F. is the whole force tending to drive the current through the entire circuit; but part of that force is used in driving the current through the resistance of the battery or dynamo; the remainder being found at the poles, and used in forcing the current through the outside circuit. That balance of pressure at the poles is called the difference of potential, and is just sufficient to send the current through the external circuit.

Let C stand for current, R for the resistance of the wire, and P for the difference of potential at the ends of the wire. Ohm's law will then read: $C = \frac{P}{R}$; that is, the cur-

rent in any wire is equal to the difference of potential at its ends divided by the resistance of the wire.

If $C = \frac{P}{R}$, then $CR = P$; that is, the resistance of any wire, multiplied by the current flowing through it, is equal to the difference of potential at its ends.

The resistance of 1 ft. of pure copper wire, one thousandth of an inch in diameter, is equal to 9.94 ohms, and if the wire used has 95 per cent. of the conductivity of pure copper, its resistance will be equal to 10.46 ohms.

Let L equal the length of the wire to the lamps, or motor, and back. Then if 1 ft. of wire one mil. in diameter equal 10.46 ohms, a length of L feet will be equal to $10.46 L$ ohms. But the resistance of a wire varies as the cross-section, that is, the greater the section the less the resistance, or, more accurately, it varies inversely as the cross-section. To use the cross section in our formula would add to the work in calculating, because it is the diameter we are after.

We may now inquire into the relation between the cross-section and diameter.

Take the case of three wires, a , b , and c having the respective diameters d_a , d_b , d_c . The cross-section of a will equal $\frac{\pi}{4} d_a^2$; that of b equals $\frac{\pi}{4} d_b^2$, and of c equals $\frac{\pi}{4} d_c^2$. π is the ratio of the circumference of a circle to its diameter.

From the above we see that $\frac{\pi}{4}$ is a constant, for the expression appears in each case; the only thing that varies is d^2 .

We therefore conclude that the section varies directly as the square of the diameter, which will make the resistance vary inversely as the square of the diameter.

We may now write for the resistance of our wire of length L in feet: $R = \frac{10.46 L}{D^2}$; D being the diameter of a wire expressed in thousandths of an inch or mils.; and D^2 being consequently expressed in circular mils.

Now as the potential, P , required to force the current, C , through a given resistance, R , is equal to the product of the resistance and current, the potential lost in the wire of length L will equal $\frac{10.46 L C^2}{D^2}$.

If P is the potential required to run the lamps or motor, and N the percentage of P to be lost in the wire, the amount of potential or electric pressure lost will equal $P N$. As $P N$ is the potential to be lost in the wire, these two quantities must be equal to each other; that is, $P N = \frac{10.46 L C^2}{D^2}$ and $P N D^2 = 10.46 L C^2$.

Therefore, $D^2 = \frac{10.46 L C^2}{P N}$ and $D = \sqrt{\frac{10.46 L C^2}{P N}}$.

Tables containing the different sizes of wire and their diameters can be readily obtained of manufacturers, and as we now know the diameter, we can, by referring to the table, find the corresponding size.

Anyone acquainted with the laws governing the flow of current may readily develop such a formula, and to show how short and clear the above formula is, we may write it as a rule in arithmetic would be written, as follows:—

Multiply the resistance of 1 ft. of wire .001 in. in diameter of the given material by its length in feet and by the current flowing through it, divide this number by the product of the potential required by the lamps or motor, and the percentage to be lost, and take the square root of the quotient; the result will be the required diameter. Anyone on comparing the two will see that the formula is much easier and its meaning less liable to be misconstrued. It may be remembered that Sir William Thomson gives the following law for determining the percentage to be lost in the wire: In any system the greatest economy is attained when the cost of the energy lost in heating the wires equals the interest on the cost of the copper.

Theory of Diamagnetism.—According to many physicists, Weber and Tyndall amongst others, diamagnetic bodies take, under the influence of magnets, a state of polarity opposite to that which is taken by iron under the same conditions, and this opinion has become classic in teaching. M. Blondlot, however, according to *Cassius*, has demonstrated that in reality diamagnetic polarity does not exist at all; and that, following the opinion of Becquerel, all substances and the air itself are, in reality, paramagnetic, a diamagnetic substance being only a substance less magnetic than the air. He recalls, in the first place, the experiments which led Tyndall to his conclusions. A bar of bismuth, placed on a coil and submitted to the action of a powerful electro-magnet, takes contrary poles to those which a bar of iron takes under the same conditions. The experiments of M. Blondlot show that bismuth becomes magnetic in the same manner as iron, but that the change in its polarity arises from the fact that the medium which surrounded it is more magnetic than itself, when the medium is air. He replaced the bar of bismuth by a tube filled with a weak solution of perchloride of iron in methylated spirits. This tube is magnetic, and becomes magnetic in the same manner as the bar of iron when it is in air, a medium less magnetic than itself. But when it is plunged in a vessel containing a concentrated solution of perchloride of iron, a medium more magnetic than itself, it becomes magnetic like the bar of bismuth of Tyndall's experiment.

MOTORS FOR NAVAL AND MILITARY USE.*

BY LIEUT. B. A. FISKE.

The reply of Clerk Maxwell, when near his death, to the question, "What has been the greatest discovery of the age?" "That the Gramme machine is reversible," shows, in the light of recent years, an inspiration almost prophetic. Granting all the benefit to mankind resulting from the numerous other discoveries with which the century has been laden, surely none surpass in far-reaching consequences the very simple one that, if a current of electricity be sent through a dynamo from an external source, the dynamo will at once become a motor—i.e., an engine, and the most efficient engine known.

But so rapid has been the development of the electric motor, that many persons, whose attention has been devoted to other things, have failed to grasp its full significance; and the object of the present paper is to present a brief statement, showing, not that the electric motor is a piece of apparatus of possible usefulness in the future, but that it is to-day a complete, durable, and strong engine, better adapted for handling guns in ships and forts than steam, hydraulic, or pneumatic engines, and more desirable for use in ships for certain auxiliaries than the numerous little steam-engines with which they are filled.

On the principle that it is best to begin at the beginning, Faraday's pregnant discovery may be recalled, that the movement of a coil of wire near a magnet pole produces a current of electricity in the wire, and the action of the dynamo at once stands out clear, because a dynamo is nothing more than an apparatus for revolving a coil of wire near a magnet pole, or, more strictly, for revolving several coils of wire between two magnet poles. Between these poles is the "armature," consisting of a number of coils of wire so mounted on an axis as to be capable of revolution. If this armature be revolved by any means whatever, such as a steam engine, a current of electricity will be produced in the coils, which will pass to the outside wires by means of the stationary brass strips or "brushes." For convenience, this wire is usually wrapped around the magnets, in order to avoid using an external source of electricity to produce the magnetism. Now, though the shape of the magnets and the armature may be varied in a thousand ways, this is all there is in a dynamo that is essential.

If the armature is not revolved, no electricity is of course produced; but if we send a current of electricity from an external source through the dynamo, it at once revolves in the opposite direction, exactly as would a rotary pump if we sent a stream of water through it, and the amount of work which the dynamo or motor will be capable of doing will depend entirely on its size and the amount of current sent through it.

Perceive the simplicity of this engine—a heavy and strong electro-magnet, a pair of brass brushes, and one revolving part, the armature composed of wrought iron wrapped with copper wire and strengthened with metallic bands. This is all: no valves, no stuffing boxes, no glands, no packing, no crank pins, no reciprocation of parts, with consequent and inevitable lost motion, no water in cylinders, no perceptible radiation of heat, no smell, no thump, and almost no liability to get out of order. Anyone desiring to see for himself the uniform and unattended performance of an electric motor can easily get permission to visit the operating room of the Gold and Stock Telegraph Co., in New York, and watch the electric motor running the transmitter which furnishes stock quotations to the city. It requires very little familiarity with the printing telegraph to perceive that the transmitter which controls quotations involving millions of dollars must run with absolute regularity under all conditions; and the visitor will find in one corner of the room, out of the way, and almost out of sight, a motor of about 3 h.p. running so silently as to be almost inaudible. And there it has run for three years, patiently performing its allotted task, simply asking that its two or three oil cups are occasionally filled, and its two brass brushes occasionally replaced. Yet the armature is balanced so nicely, that it would require very long-continued neglect of oiling to do much harm; and the only injury that would occur if the brushes were neglected for, say a day, would

be one easily remedied, and unattended with the slightest danger.

On board the "Atalanta" we have a steam capstan on the forward berth deck, supplied with steam by a 4 in. pipe and connected to the auxiliary condenser by a 4 in. pipe. By reason of the distance between this engine and the boilers, with the consequent friction in the pipes and condensation, the steam pressure is much reduced, and the back pressure much increased, so that a larger engine is necessary than would otherwise be the case, and, which is not astonishing, it has been known to run very much faster in weighing anchor, when exhausting into the atmosphere and covering the fore-castle with a cloud of steam, than when exhausting into the condenser. Now, an electric motor for running the capstan would not only have the advantages already mentioned, but could be connected with the same main wires as those furnishing the electric lights by two wires, say 1/2 in. diameter, thus avoiding altogether the expensive copper pipes, tinned on both sides and lagged.

The same remarks apply to the blowing engines, and one has simply to watch for a few minutes the comparative performance of even the best steam blowing engine and an electric motor, with the fan on the same shaft, to become convinced of the superiority of the latter.

For pumps, except the pumps very near the boilers, where the length of piping is short, electric motors would have the advantages mentioned above, and no disadvantages whatever.

For steering engines the simplicity of the apparatus, the quickness with which the motor could be handled, its freedom from liability to derangement, its absence of heat, and its noiselessness would commend it to anyone who has ever been shipmate with a steam-steering engine like the one on board the "Atalanta," which, though efficient and reliable, is as complicated as a printing telegraph, keeps the after end of the ship almost at a cherry-red heat, and threatens to shake the teeth out of the officers and crew every time the helm is put hard over.

Three years ago the ability of electric motors to train guns was shown to the authorities in England, and since that time much progress has been made in perfecting the apparatus for applying electric motors to this kind of work. Little difficulty has been experienced, for, though there is nothing that requires such accurate and rapid handling as a great gun in a scaway, there is no other engine capable of such accurate and rapid work as an electric motor, and its advantages over steam, hydraulic, and pneumatic engines are so marked that it would be idle to compare them. The indications now are that we shall have at least one gun in the "Chicago" trained by electricity, though possibly this may not be done, since the dynamos for generating the necessary electricity have been placed above the water-line and exposed to the enemy's projectile, while the beef, pork, bread, &c., have been placed below the water-line and securely protected therefrom.

But it is not in the training of the guns alone that motors can be advantageously employed; they can also be used in elevating. In the "Atalanta," when rolling from 10 deg. to 20 deg. each side, and from ten to twelve times per minute, the line of sight of the guns sweeps past the horizon so fast, even near the end of a roll, as to require from the gun captain a rare degree of skill if we would have him shoot as accurately as such fine guns should be shot. The trouble is that the gun is beyond his control except in the matter of training, because the most that he can do is to wait for a favourable time of roll and catch the line of sight on the target as best he can. To use the gun effectively he needs some arrangement by which he can put the gun on the target and keep it there, independently of the rolling of the ship. He needs some arrangement like the shoulder-piece of the Hotchkiss guns, by means of which experiments on this ship have shown a very little practice enables a man to keep the line of sights almost exactly on the horizon or on any other object.

Electricity puts this power directly into the hand of the gun captain; for by means of a small electric motor on the elevating gear and a suitable switch, he can raise, or lower, or stop the gun by simply moving his hand. The gun captain being able to train the gun to the right or the left, and to raise it up or down, the only thing left to do is

* From the Army and Navy Journal (U.S.).

to give him an electric primer, fired by means of an ordinary "push button," so that he can fire the gun quickly when the sights come on, instead of losing time by hauling on a look lanyard.

The advantage of this quick means of firing by using the electric primer stands out clear when we recollect that in a ship, say the "Atlanta," which rolls in a seaway about 3deg. per second on the average, an error on the part of the gun captain of only $\frac{1}{15}$ th of a second of time means a vertical error, on a target a sea mile distant, of about 31ft. This remark applies, of course, only to the individual firing, and not to broadside firing by electricity, the advantages of which are not so palpable.

A very neat use for electric motors would be for hoisting ammunition. On board the "Atlanta" we use five men at each shell hatch, and their work could be done more quickly and quietly by a 2-h.p. motor costing, say, 200 dolrs. This would require one man to operate it, and would leave four men from each hatch for work at the guns. Coal could be similarly hoisted on board, and how refreshing it would be in coaling a ship to see two 5-h.p. motors running up the coal bags, instead of a long line of dirty men, hopelessly dragging on the yard and stay from morning till night, while the officer of the deck, a respectable man of forty, and the father of a family, incessantly and mechanically hawls at them to "haul away!"

But it may be objected that electric motors entail loss of energy, since steam-engines use steam direct from the boilers, whereas motors require dynamos to generate the necessary current, the dynamos themselves being turned by steam engines, so that there are two losses—one loss in connecting the mechanical energy of the steam engine into electrical energy; the other loss in reconnecting the electrical energy of the current into the mechanical energy of the motor. To this it may be answered that 15 per cent. loss for each transformation is a very fair allowance, so that the motor would deliver about 72 per cent. of the energy of the dynamo's engine; and it may be doubted if the auxiliaries which are at any considerable distance from the boilers work with more than 72 per cent. of the difference in pressure between the boilers and the condenser, by reason of the loss in friction and condensation in the steam and exhaust pipes. In fact, in engines which run intermittently, like capstan, steering, and gun-training engines, it may be doubted if any such efficiency as this is even approximated. This is a fair comparison, because the dynamo engine can be very near the boilers.

Since all our new ships are fitted with dynamos for feeding electric lights, why not have them feed electric motors also, every horse power developed by the motors being about the same thing as adding, say, nine 16 c.p. lights. Of course, the dynamos must be safe below the water line, and they must all be similar, and feed into the same main wires, which go all through the ship like gas pipes through a city, the incandescent lights, search lights, and motors receiving their supply from these main wires, and one, two, or three dynamos being run at a time, according to the number of lights and motors in use. Nothing could be more simple and effective than such an arrangement, and nothing could contribute more to the efficiency, health, and comfort of a ship.

To summarise, the advantages of electric motors, in ships and forts over steam, pneumatic and hydraulic engines are:—

1. They are more simple.
2. They are more durable.
3. They are more quiet.
4. They are more clean.
5. They have no swell.
6. They require less attention.
7. They avoid the troublesome and very expensive operation of leading steam and water pipes through a ship, especially through water tight bulkheads.
8. The wires take up less space than pipes, a great point in crowded engine rooms and firerooms.
9. A water or steam pipe presents a much larger target than a wire, and is therefore more liable to be struck in action.
10. If a steam pipe or a water pipe is struck in action, the deck is filled with scalding steam, or is flooded with

water under high pressure. All the engines depending on it are put *hors de combat*, and it is quite impossible to repair it; whereas, if an electric wire is so struck it can be repaired in a minute by simply bridging the gap with a wire.

11. The electric motor places in our grasp the best known means for handling guns, by reason of the readiness with which it is controlled.

In any ship arranged with a central of electric power and with main wires leading therefrom all over the ship, so that any desired amount of power could be obtained by simply moving a button as in lighting an incandescent lamp, a number of small portable motors could be placed wherever desired about the decks, and employed for such purposes as hoisting ammunition, coal and ashes, working the yard and stay, running lathes in the ordnance and engineer workshops, running small ventilators, &c.

The writer is aware that, in representing the benefits to arise from the use of electric motors on shipboard, he will fall under the disapproval of many of the best officers, who deem it unsailorlike to do ship work with machinery. But he feels assured that the navy is daily losing much by not seizing the advantages offered by electric motors, and that there are many officers who believe that the navy should not only preserve the glorious traditions of the past, but should also grasp the possibilities of the present. Let these note that, as said above, electric motors are no longer scientific or "theoretical" curiosities, but practical and strong machines, waiting simply to be used in order to contribute to the effectiveness, health, and comfort of our ships and forts, and that they can be bought in open market, or by advertisement, like beef and pork, and can be stowed on either the port or the starboard side. It is as certain as anything can be that naval and military people will some day use them. The only question is, will we be as slow in taking advantage of them as we were in taking advantage of steam-capstans, steam steering engines, steel ships, and square air ports?

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—May 18.

CENTRAL STATION LIGHTING: TRANSFORMERS v. ACCUMULATORS.—MR. CROMPTON'S REPLY.

Mr. R. E. Crompton, in reply to the discussion on his paper on "Central Station Lighting: Transformers v. Accumulators," said that in his replies to inquiries he would put the answers into two or three groups, which would answer others who had spoken on the same points. First, in reply to Mr. Hammond. Mr. Hammond seemed to labour under the idea that he had stigmatised his installation as an "advertising" station. What he did say was that Mr. Hammond and other similar installations were pioneer stations, established more for the idea of showing to the public what electricity could do than as being model installations of central lighting, and this, he maintained, was the case with all overhead wire systems. It would save much misunderstanding at this point, and a further misunderstanding when he came to answer Prof. Forbes, if he stated that for the purposes of this paper his object was to discuss transformers v. accumulators on their merits for certain installations as central stations for the City of London, and for this purpose overhead wires were put out of call. He wished to limit the discussion to a practical issue for such a system. Mr. Kapp criticised the load diagram shown, saying that the valley in the diagram might be filled up with power used in the day, and a larger total supplied for the same plant. He did not deny this in many cases, but London was not like New York and other cities. The offices are grouped together at the City, and, of course, the diagram for the City would be widely different, but the matter of supreme importance at this time is the lighting of the houses in which we live, for that is where we feel the full benefit, and everything we can do to forward such lighting is the most desirable at the present time. As to the sale of motive power, no doubt that was most desirable, and told in favour of the battery system, although he did not give very great weight to that point at present; in future it would help to swell the income. The capital required is proportional to the height of the peak of the load diagram, and the income is proportional to its area, therefore, the more it is filled up the better for the company. In discussing the question he had kept this point out of view, and his motives would be appreciated for keeping it thus obscured for the purpose of comparison for lighting only. Every argument he had used would be strengthened if motive power were distributed. Turning now to the discussion in his absence Mr. Kapp seemed to misunderstand the figures as to the cost of laying cables; he says, instead of using the cable proposed, costing £116 per 100 yards, he proposes using a cable covered with lead at £130, and he hopes by this expedient to save a great deal of expenditure. In this he will find himself quite wrong. He seems to think 3s. per yard will be sufficient for laying such a cable. Did he know that £25 per 100

yards is the lowest sum levied by the vestry when the roads are taken up! For ordinary pavement, 4s. a yard is the price, and for asphalt, 11s.; but if we suppose 10 per cent. only of asphalt, this will make the cost 6s. a yard, making £25 per 100 yards. Moreover, in calculating his cost of laying, Mr. Kapp makes this astonishing mistake, he thinks he can find contractors who will carry out his work at cost price, without taking a profit. How he can think he can find contractors who will consent to take up pavements and guard against contingencies, without making their profit is hard to say. Mr. Kapp having left out the amount to cover drawings, management, and profit, you will find his figures come considerably higher than mine. This is a specimen of Mr. Kapp's figures, and you will find his other objections on the score of cost will no better bear inspection. The laying of the mains will be the chief item in any coming installation. We have had no experience of the cost of laying mains until the last few years, and he really had thought it would prove of weight if he gave figures as to cost of cable actually laid. General Webber in his criticism of the culvert system misinterpreted the way in which the wires are fixed. General Webber talked of suspending the wires from the roof of culvert, if that was the case no leaky water would trickle down and reduce the insulation, but, as a matter of fact, the cables were strung on short pillars standing up in the culvert, and there was no reason to fear even if there were two or three inches of water running on the trench. It seemed to be imagined that these culverts would be stopp'd up with mud, and legions of rats would be running along. They had had over one year's experience with the culvert system, and had had no such things occur, nor any signs of such occurring. They have had the trenches open many times, more than they would in the future, and many joints made, and, in spite of all, the insulation is actually at the present moment, length for length, as high as that of the highest insulated cable yet made in the world. While on this point, he wished to make a remark upon the question of underground insulated cables. It is quite common to stipulate the resistance of a cable to be so many megohms. As long as the insulating covering remains intact, it is very easy to keep the resistance such that it can be measured by megohms; but when it has a few hundred cuts in the covering and joints are made, the resistance cannot be prevented from falling. No matter how carefully the joints are insulated afterwards, some leakage will take place at every joint, and the resistance comes down to a few thousand ohms. In speaking from practical experience, he found the joints very difficult to make electrically tight, and whoever came to plan a system with high-tension mains would find the difficulty infinitely more than with his system. As to the difficulty of placing culverts, it was true that there are some places where the culvert system could not be used. It has been thought that it was necessary to use an 18 in. culvert, but in many places he had only used 6 in. culverts. It was also thought that the cables would sag down and short-circuit. If properly run, there was no danger of this, but he should prefer a tunnel, in brickwork, between each set of cables to prevent the possibility. The greatest difficulty was in getting sufficient depth tier from cross-pipes. In some cases there was no more room than 2 in. available, when this is the case no system can be used but lead-covered cable driven through small pipes. As to the relative cost of transformers, Mr. Kapp thought that the number of transformers could be reduced, and went to the extreme of putting transformers in ten different substations. Mr. Kapp had already pointed out the saving of mains by using transformers, but by using ten distributing transformers he will use just as much copper as in distributing from ten battery stations. Mr. Kapp would therefore, have to adjust his figures, and by this means he must add £6,000, and in addition sub-stations from the end to the charging mains, about £3,000 or £4,000 more. That is an addition of £10,000 for a gain of £5,500 in cost of transformers. This is a specimen of Mr. Kapp's proposal to reduce the cost. From what had been learnt from Prof. Forbes, however, he did not think that Mr. Kapp's proposal would be carried out, but a transformer would be put in to every house, or at least, one for each two houses £15 for each two houses would not be too much to include profit and similar charges, and he did not see how this figure could be reduced. He might just touch on the question of efficiency at low rates of output. In the transformer system, 40 per cent. of the total output is taken at extremely low rates of efficiency, a transformer of 4,000 watts capacity giving 180 watts. During the corresponding time the efficiency of the accumulator is at its highest. Mr. Swanburne made the remark that transformers could be made to give as great an efficiency at low as high rates of output—that is, that they could be compensated. The truth was, the transformers "compounded down," the E.M.F. falls as the current falls, and the manufacturers of transformers have not yet succeeded in writing them so as to obviate this. This brings us to another point, which, apparently, he had not sufficiently dwelt upon. The paper did not deal with accumulators simply as stores of energy, but dealt with accumulators as transformers; and, although many persons have discussed the objections to the storage battery, Mr. Drake was the only person who dealt with their advantages from this point of view. There are two distinct plans of using batteries in a distributing plant—the one, in which batteries are interposed in the charging circuit, and transform a high-tension current into a low-tension current, having at the same time a storage capacity in case of breakdown, and for sudden increase of output; the other plan is that in which the batteries are filled during the daytime and discharged at night. Mr. King had alluded to the installation of Colchester, and asked why he had not referred to it. The arrangement at Colchester was so different from that he was now advocating that it is out of count; the number of batteries would have to be multiplied by six if used as they were used at Colchester. You would see that after all he was a very timid user of batteries; no doubt as experience extended he should use them much more largely, and we may be able to have the mains reduced, and have more distributing stations and larger generating plant, but the whole of the figures given were based on experience up to this present moment. He had done it

before and could do it again, whereas, even what was supposed about the transformer system had not been done yet. He had been called to account for not publishing the figures of the Vienna installation. He did not choose to publish those figures for this reason, that he was contractor to the company, and put it to the audience, would they, being contractors, publish figures which might endanger their position as contractors to the company. But he would do this, he would agree to take, say, Sir Wm. Thomson to Vienna, and prove to him that there was not the least difficulty, or hitch, or danger to life or limb, with the battery system there in use. Prof. Forbes speaks with depreciation of an insignificant installation of 10,000 lights, and I say the proper basis is 100,000, but Prof. Forbes might notice that 20,000 yards of wire was allowed, and that 10,000 lights is one-tenth of 100,000, and I might very reasonably expect to increase to that amount without much difficulty. Mr. Kapp objects to the cost of accumulator stations saying that £150 extra must be allowed. The sum of £50 is the rent now actually paid for stable and coach-houses, and there are at least a dozen others offered at this price, and, more than this, a single room cannot be had for much less than this. People do not care about letting part of their houses. As to the efficiency of the accumulators, Mr. Parker doubts whether 80 per cent. efficiency can be obtained with the accumulators. In reply he could only state that this efficiency is obtained at Vienna, and higher efficiency has been obtained. It is easy to understand that this can be done when the batteries are used as transformers and not as mere storage batteries to be charged in the day and discharged in the evening. In the first case it is the watt efficiency that must be taken, the watts at the dynamo divided by the watts at the terminals of battery, in the second, current efficiency only. Here watt efficiency was spoken of, and that loss of conversion is not always to be taken into account is due to the fact that when the batteries are connected in series and taken off in parallel if there is no leakage there is no loss and leakage across the terminals can be guarded against, and need not occur. It is more likely to occur in a private installation, but in a large installation there is sufficient staff to prevent this loss, and it pays to prevent it. Forty per cent. of the total output went a low rate of output, on which there is no loss; the remainder is at 80 per cent. efficiency, the total efficiency over wires and all is over 70 per cent. As to the depreciation of accumulators, all the experience we have goes to prove that we are well within the mark when we say we can guarantee a depreciation of not more than 12½ per cent. The company at Vienna are not willing to allow anyone to contract, even at 10 per cent., finding that they can do it themselves for less. The experience at Kensington Court has shown a depreciation during 15 months of about 2 per cent. There is a battery at Chelmsford, which is in exactly the same state as it was last year, and has not lost one penny in depreciation, and there was no reason why it should during the next year. It has not been lightly used either, having been in more or less constant use, giving large currents for calibrating instruments. Mr. Kapp objects to 4 per cent. variation, and suggests 2 per cent. We have found no trouble in this respect, and think, as long as it is not exceeded, 4 per cent. would not be grumbled at. Mr. Hammond says that practically, engines do not fail suddenly, but always give some warning. All he could say is that in Mr. Hammond's experience must be very favourable; his own experience was that engines stop just when they ought not, a journal of a big engine gets heated a few revolutions, and it slows down. How about the belt coming off? It must stop suddenly then, and have we never heard of such a thing as the belt breaking? At all events this is what you can do with accumulators; you can stop right in the middle of the busiest time for two or three hours for repairs. In one case they had been able to stop the engine and get up steam in another boiler without the people knowing anything at all about it. Now as to Prof. Forbes' remarks. A large proportion of Prof. Forbes' remarks were mere carrying criticism. He would take a few of his remarks, and the audience might judge for themselves. He says there are only two cases of actual experience in the paper, and both of them are "hearsay" evidence. If Prof. Forbes will look at the paper, he will see that in both cases of what he calls "hearsay" evidence was about accumulators made by other people. He could answer for his own experience, but in the case of the accumulators made by Elwell and Parker, or by the E.P.S. Company, he took what they said, and they should know. He really did not think that he was the one to be accused of speaking from "hearsay" evidence. He asked, Has there been any paper given before this society in which there has been so much real practical, commercial, contractor's experience, as the one now brought before it? Of theories and principles we have had sufficient, but of real practical experience very little. He felt sore on this point, as he had tried to give some really useful information, and put himself to a good deal of trouble and expense over the matter, and was now told that it is of no practical use by Prof. Forbes, who does not know himself the cost of laying a main, who never paid a contractor, who never checked a contractor's account, and practically knows no more about well, Prof. Forbes ought to be very good at figures, but he is not good at contracts. Prof. Forbes says the reserve is too much—1,450 h.p. he thinks is far too much; and gravely informs us that Mr. Westinghouse gets 600 kilo-watts from 1,000 h.p.,—that is, 81 per cent. e.h.p., as if effective e.h.p. in the cylinder were the same as effective e.h.p. at the terminals of the lamps. Never was there such argument. What is more, he further we are rather below par in making engines and dynamos. Let him tell Prof. Forbes that Williams and Robinson, down at Thames Ditton make the best engine for dynamos. Westinghouse has simply copied the Williams engine—copied everything, and a very bad copy too—and is supposed to get 12 per cent. greater efficiency than the original, and this is in the highest part of the scale, when every increase of efficiency is so difficult to obtain. Is it actually likely, when Prof. Forbes accepts such statements as these, that his strictures on what we are able to manufacture are very good, and the rest of his strictures may be measured by this. The best result we have obtained in England after trials and competitive results,

including loss in feeding mains, dynamo friction of engine, is a loss of 18 per cent. from the calculated i.h.p. in cylinder. Instead of 1,000 h.p., therefore, 1,200 would be the number. 1,240 would not be excessive, and 210 h.p. is not an excessive reserve. The question of cost of mains he must decline to discuss with Prof. Forbes, because he has based everything on the system of overhead mains, and overhead mains will never be allowed as a permanent large distributing system in this country. He had now, he thought, answered all the objections. Figures were worth more than opinions, and on nearly all grounds the B.T. system is overwhelmingly superior. No doubt the cost of transformer systems might be reduced. The Grosvenor Gallery Company have been very silent about their coal bill, but from what we can learn their experience has been that the consumption of coal for each a.h.p. was nearly 18lb. of coal; it should be more like a quarter of this. He hoped to have the opportunity at no distant date of setting before them full facts and figures on the consumption of coal. The battery system, he maintained, then, is less expensive, needs smaller plant, need not be always running, the labour is very much less, the likelihood of breakdown at the height of supply practically abolished. When he put these together, he thought he had prepared a very formidable array of figures against the transformer system. If at some future date someone can give further figures and a different result, he should be very pleased to listen to them. In conclusion, Mr. Crompton said he would like to bear witness to the fact that Prof. Forbes had drawn attention to the subject of the great advantage of bare underground cables at much about one and the same time as himself.

Lord Crawford said he thought Mr. Crompton had been misinformed on the point of the coal consumption at the Grosvenor Gallery. His informant had probably omitted the decimal point in his statement of 18lb. of coal per a.h.p.

FIRE RISKS INCIDENTAL TO ELECTRIC LIGHTING.

After Mr. Crompton's reply to the criticisms on his paper, the discussion on Mr. Preece's paper was continued by **Mr. Musgrave Heaphy**, who said: At the last meeting I asked and obtained permission to make a statement this evening as to the reason the sittings of your committee on the office rules were interrupted, for I felt the account given by Mr. Preece unintentionally conveyed an erroneous impression. Had it not been for that remark I should not have spoken at all, for obvious reasons. In May last a committee of your council was formed to draw up a set of rules from the rules of 1883. Communications were opened with the Phoenix on the matter, the result being that a tentative agreement was arrived at, that in order to settle once for all any difficulties as to rules for the future, the Telegraph rules and the Phoenix rules should come out under the same cover, the cover to contain no mention of the Phoenix. The first portion of the pamphlet was to contain general rules and principles for installations drawn up by your committee, the second portion of the pamphlet the Phoenix detailed rules for installations, there being an acknowledgment clause that these detailed rules were the Phoenix rules. In making certain that there was nothing in the Phoenix rules that would be objectionable, four gentlemen of your committee were to form a sub-committee, and to go over them, clause by clause, word for word, and in the event of our not agreeing, the arrangement was to come to an end. These gentlemen were to be men practically acquainted with the difficulties of electric light installations. They were Mr. Preece, Mr. Siemens, Mr. Crompton, and Major-General Webber, and it is impossible to thank those gentlemen too much for the time and care and labour bestowed, especially Mr. Preece, and I am sure that had the matter been in their hands I should not have been so unfortunate as to trouble you this evening with my remarks. We had many sittings at the office of your society without the slightest hitch or difficulty of any kind, and the Phoenix rules were unanimously approved after certain verbal alterations had been made, and a few other very slight variations. The acknowledgment clause was then framed and agreed to. The sub-committee then revised their general rules; with these I had nothing to do. These general rules were not those that your committee has recently issued. [Here Mr. Heaphy showed the pamphlet pointed.] I thought the matter was now at an end, so far as I was concerned, when I received a letter asking me to attend your committee to explain certain rules. I thought this strange, as the matter had been so thoroughly gone into by the sub-committee that they would be conversant with every point; but I accordingly went, when, to my surprise, the first thing I heard spoken was the acknowledgment clause called into question, with an intimation that instead of the detailed rules being acknowledged as the Phoenix rules they should be called rules based on the Phoenix. I also found that the whole of the Phoenix rules were to be gone over again—not the original Phoenix rules in the Phoenix cover, but the very slightly altered Phoenix rules that were in the cover of the Telegraph Engineers. What, then, was the position of the Phoenix? Their rules might again have been slightly altered, verbally, and the acknowledgment clause altered objectionably, and all copyright lost; perhaps the very name of Phoenix might have been expunged in the next edition altogether, and what remedy would the Phoenix have had? None. If it objected, the answer might have been. The detailed rules had been drawn up with the consent of your own representative, sitting as one of the committee; you cannot now refuse to recognise these rules, nor object to the acknowledgment clause whatever it may be. Gentlemen, the Phoenix Fire Office after a time might have been entirely deprived of its rules. I only say, might. What was the only course open to the Phoenix? What would any of you have done? Why, what the Phoenix did—say that unless the acknowledgment clause was to stand as agreed upon, in the event of your committee being satisfied with the rules, it must retire from all

negotiation. It then writes this letter: there is not time now to read it, but I do hope that your committee will allow it to be printed in its proceedings. I attended the next meeting, when your committee declined to give me any information until the sittings on the Phoenix rules in their pamphlet had been completed, I to sit with them. Gentlemen, I had nothing left but to retire. Several gentlemen on the committee asked me to stop, saying I could reckon on their support. That I knew; but when I said that you might possibly be out-voted by others of a different opinion, thereply was, "Yes, that might be so." I do not wish for one moment to impute that your committee would have done anything that it did not consider right and honourable. I do not wish to cast the slightest imputation upon any one of them, but there are often two different ways of regarding the same thing, and what would seem perfectly fair and right from one view would be felt as a bitter wrong and injustice from another. Let me give you an instance. A speaker, last Thursday, in this room, actually stated in effect that, because some of the clauses in the Phoenix rules which were brought out in February, 1882, were then similar to certain rules in America, therefore, there is no right to copyright in the present Phoenix rules, notwithstanding all the original thought and labour bestowed upon them to make them perfect, that an installation put up by them is a different one in this country from installations elsewhere, and that thought treating upon systems of lighting undisturbed of six years ago ought not to be monopolised by anyone who chooses to appropriate it. Gentlemen, I can assure you that the Phoenix has always been, and is now, most willing and anxious to do everything that is just and right, but it does consider that fairness should be shown to it in return. Gentlemen, you know what injustice is. You have had to feel the tyranny of Chamberlain's Act, but that Act is mercy itself compared with the one that is now sought to be imposed. You had 21 years allowed you before your work was confiscated. The Phoenix rules are not to be granted any time at all. I will never believe, gentlemen, that you will be a party to such an injustice.

Mr. Hubert rose to explain upon one point. On the last occasion there was mention made of the minimum of electric resistance allowable in insulated covering of electric cables. Mr. Preece had advocated a minimum of total leakage, and had specified 1/10th of the total current—that is to say, a leakage enough to light one lamp, if the installation was for 5,000 lamps. The fire officers wanted to have the best practical rule, and he did not think that this was as good a method of testing as by resistance. Those in the trade could easily measure to so many meg-ohms in resistance, and, of course, in an installation of 5,000 lamps, one lamp would be lighted by the leak. That would be plain. But what he wished to ask about was the case of a small installation, such as they often had to deal with, where, perhaps, only 10, 20 or 30 ampères were used. He would like to ask experts if they could readily and correctly measure, say, 1/10th of 15 ampères.

Lord Crawford said: When rules were multiplied weaknesses also multiplied, for each rule might become a weak point. Practical men of high moral tone would not take advantage of these weak points. Contractors who were not so particular would do so, and the installation, while still technically complying with the rules, might still be unsatisfactory. The Phoenix Fire Office was the first to take the matter up from the point of view of fire risks; the rules published in the *Times* newspaper for 1882 were the first basis upon which they had proceeded. Other offices remained inert. To them electric lighting was an unknown factor; they refused to have anything to do with it for fear they might burn their fingers. We are all greatly indebted to the Phoenix for stepping into the breach and grappling with the question firmly and nobly. They have spent much time and trouble, and have advanced with every advance of science. We have found at the Grosvenor Gallery the Phoenix rules as satisfactory as any that could be framed, and we have had the largest experience in London. We are putting on lights at the rate of ten houses a day, the wiring of these is all supplied by the customers themselves, and we have naturally to insist upon such work as shall not endanger our system or our credit. We have come to the definite determination to have all such installations wired according to the Phoenix rules, and when they had not been so wired, or had been passed by other offices, we insisted upon them being inspected and passed again under the Phoenix regulations before the current was turned into the house. We have a great stake in this matter, and any public building suddenly falling through fault of the contractors is at once laid to us. A man cannot get the best work done unless he is able to pay the price for good workmen, and the sooner the bogus installation-mongers are stamped out the sooner will electric lighting take its proper place as a necessity in London.

Mr. Wharton said he did not think any alteration was required in the rules at present. There were two parties principally interested to consult—the contractors and the fire offices. As a contractor, he did not want any alteration. Fires have not occurred in installations wired under the rules, and although Mr. Heaphy was strict, he was not too strict, and was always open to modification if real necessity were shown to him. Did the fire offices require any alteration? He did not think so. Up to that moment he believed he was quite correct in saying not one fire had occurred in installations passed by the Phoenix office. [Mr. Heaphy: Not one.] These were therefore, the parties most concerned, and the rules were, he thought, now as good as they can be, and any alterations could only be for the worse.

Mr. Shoobrod thought a good deal of feeling had been imported into the discussion which was not within the scope of the paper. It was to be understood that these rules were not to supersede those of the fire offices, but to definitely state the scientific principle from which such rules could be properly derived.

Mr. Marlborough Pryor, director of the Sun Fire Office, chairman of the Fire Offices Committee, said he had objected to the statement upon the copy of the rules, that they were "accepted by the leading fire

offices," because that was not the fact; there were many of the leading fire-offices who had not accepted these rules. He objected to the necessity, evidently insisted upon in these rules, that every house which was fitted with electric light should be personally inspected by the fire-office inspectors. He did not think there was any more necessity to inspect every individual house, than with gas. It was not the business of fire-offices to trouble householders continually about the electric light. If they had to have an army of inspectors the premiums would have to be raised to recruit themselves. They therefore did not accept these rules, which were drawn up, so as to require the inspection of each installation. They wished rules that will sufficiently cover all cases without individual inspection.

Mr. Rawlins said he hoped they would be able to produce rules which would apply under all circumstances, which were not "copy-right," for which there was no charge and which did not require a paid interpreter to interpret them for actual use in installations.

Mr. Hammond said that he would like to take the opportunity while so many representatives of the fire-offices were present to tell them that what all the electrical engineers were looking forward to from them was not only no advance, but a reduction. He thought they should allow a 15 per cent. reduction on all houses lighted by electricity.

Mr. Prescott, in reply, said his hope in reading the paper was that in bringing before the society a series of experiences in cases of failure and accident, it would lead other men of practical experience and scientific knowledge to give other instances which might have led to some further development of the subject. Unfortunately, quite a number of subjects quite foreign to the risks incurred in electric lighting had been inported into the discussion. He had no wish to refer to all of these. There was one thing he would like to point out, that it had been said that the risks incidental to electric lighting was a question solely between the fire-offices and the contractors. It seemed to him the chief risk was with a third party—the users. The chief regard should be to protect the users from the rapacity of certain contractors. Of course, there were contractors and contractors, but with competition so severe there were many contractors who will take all means of making a profit who will even send orders to manufacturers which respectable manufacturers would not care to execute. This discussion was another illustration of the old proverb, "a man convinced against his will is of the same opinion still." He did not think the discussion either on the accumulators and transformers, or on the fire-risks, had converted a single man who had listened. It was true they had passed several very pleasant evenings, more pleasant, perhaps, than even at theatre. There was just one point which should be referred to with regard to the continued rules in one cover referred to by Mr. Heaphy which they had had discussed before them that evening. Those rules were not printed by the Society of Telegraph Engineers at all, but were printed in that form by the Phoenix Fire Office. With regard to the further intention of bringing the fire-offices and the telegraph engineers together, he was always quite ready to do all he could in the matter. In reply to the question as to whether it was possible to measure one five thousandth of 15 amperes, he did not suppose there was any electrician in the room who could not measure a current of three milli-amperes which was one five thousandth of 15 amperes—it was one of the simplest every day problems of an electrician. Mr. Shoolbred had asked him a most interesting question, that with regard to the heating capacity of wires. This question was one which had occupied him more than any other during the last five or six years, and had dealt with this in recent papers before the Royal Institution and the British Association. In the last paper read a set of constants were given, which will enable anyone to find out what current will fuse any wire, of any diameter, of any usual material. This rule he was endeavouring to apply to insulated electric light wires, and hoped to give the result before long. Prof. George Forbes had given a table on which the radiation at normal tables was calculated, and Mr. Robert Sabine not long before had done the same thing, but for this general rule we cannot determine the heating of electric wires; and there was Mr. Macfarlane's experiments on Sir Wm Thomson's laboratory in Glasgow, who showed that "conductivity"—that is, at the rate of loss of heat per unit area of a copper sphere—could be expressed by a constant. There was every reason to believe that a similar constant was applicable to copper cylinders. The experiment was made with brightened and blackened copper spheres. We may have experiments which will give us radiation from bare and covered cables, and enable us to calculate the exact loss from heating with any given current. In conclusion, he could only express regret that more had not come of his idea of bringing out experiences of actual risks connected with electric lighting, but the question remained to be discussed, and he hoped it might at some future time be brought forward by some more competent person.

PROVISIONAL PATENTS, 1888.

MAY 11.

7035. **An electrical coupling.** William Edward Langdon, Telegraph Department, Midland Railway, Derby.

MAY 12.

7083. **Improvements in electro-medical batteries.** Thomas Wm. Ford, Ash Villa, Oxford-road, Caversham, Berkshire.
7102. **Improvements in apparatus or appliances for automatically obtaining light by electricity applicable for lighting cigars, pipes, and the like purposes.** Charles Henry Barnes, 33, Chancery-lane, London.

7105. **Improvements in compasses.** William Cooper Cooper, 24, Southampton Buildings London, W.C.

MAY 14.

7111. **Improvements in electrical couplings, partly applicable to other purposes.** John Hubert Davies, 3, Barry-terrace, Westbourne square, Paddington, W.

7131. **Improved apparatus for measuring and regulating electric potentials and currents.** Sir William Thomson, 115, St. Vincent street, Glasgow.

MAY 16.

7256. **An improved combined holder, switch, and cut-out for electric glow lamps.** Frank Rowling, 2, East Parade, Leeds, Yorkshire.

MAY 17.

7301. **Improved apparatus for measuring and regulating electric potentials and currents.** Sir William Thomson, 115, St. Vincent street, Glasgow.

7308. **Electric date and time printing stamps.** Charles Adams Randall, 19, St. Swithin's-lane, London, E.C.

7321. **An improvement connected with accumulator jars or other receptacles for holding plates of metal or the peroxide plates and negatives for electrical storage batteries.** John Kent and Frederick John Beaumont, 9 and 10, Railway Approach, London Bridge, S.E.

7332. **Improvements in and connected with conductors of electricity.** Henry Edwards, 47, Lincoln's inn-fields, London.

7353. **Improved electrolytes for electric batteries.** Robert M. Kenzie, 47, Lincoln's inn-fields, London. (Henry Weymorsch, France.)

7355. **An improvement in field telegraph and other similar conductors.** Richard von Fischer Treunfeld, 28, Southampton-buildings, Chancery-lane, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MAY 10, 1887.

6809. **Improvements in electric bell indicators.** John Eshelby and Edwin Eshelby, 5, Eden quay, Dublin.

MAY 11, 1887.

6918. **Improvements in telegraphy.** William Edward Gedge, 11, Wellington street, London. (Auguste Claude, France.)

MAY 13, 1887.

7042. **Improvements in electric arc lamps.** Frederick George Chapman, Fred Mitchell Dearing, and William George Chapman, 1, Queen Victoria-street, London, E.C.

JULY 13, 1887.

9829. **Improvements in dynamo-electric machines.** Thomas Stanley, 8, Quality-court, London.

JULY 21, 1887.

- 10,195. **Improvements in dynamo-electric machines.** Joseph Platt Hall, 4, Mansfield-chambers, 17, St. Ann's square, Manchester.

JULY 30, 1887.

- 10,575. **Improvements in instruments for electric measurement.** Walter Emmott and John Hall Ruler, The Northern Telegraph Works, Halifax, Yorkshire.

NOVEMBER 16, 1887.

- 15,717. **Electrical date and time stamp.** Charles Adams Randall, 7, Alfred street, Brimpton.

CITY NOTES.

Dalmatia Mining and Electric Power Company.—The Dalmatia Mining and Electric Power Company, Limited, office is at 3, Queen-street.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the week ended May 18 were estimated at £5,326.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company for the week ended May 18, after deducting the fifth % of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, were £4,405.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company, for the best month ending May 15 were £2,802, as compared with £2,297 in the corresponding period of 1887, showing an increase of £523.

Protean Battery Syndicate, Limited.—This syndicate was registered, with a capital of £5,000 in £10 shares, to carry on business as electricians, and for such purposes to adopt an agreement of February 2nd, between Mr. W. Kingdon and Mr. M. Norworthy. The subscribers include Mr. M. Norworthy, Old Broad-street; Mr. E. R. Gibson, Lloyd's; Mr. P. Lloyd, Old Broad-street, and Mr. J. Davies, Finsbury-square. Registered without special articles.

Government and the Telephones. The war on this question is being kept up in the columns of the *Financial News*. The aim of the paper, and in fact most of the financial papers, seems to be to attempt

to put some backbone into the management of the United Company. The *Economist* recently condemned the colourless and inanimate policy of the United, and is congratulated upon this fact by the *Financial News*. During the past week the columns of the latter have been opened to a correspondence on the subject, in the course of which Mr. A. A. Campbell Swinton says: "The Post Office is not, however, the only competitor with whom the United and its subsidiary companies will have eventually to deal. Even at the present moment, and in spite of the virtual patent monopoly enjoyed by these companies, the most important of the two telephone exchanges existing in Sheffield is a private venture entirely distinct from and out of the control of these companies, and when the United Company's Bell and Edison patents have expired (the Bell patent expires December, 1890 and the Edison July, 1891), or when, what is perhaps more probable than the United Company and its supporters find it convenient to assume, the Equitable Telephone Association is successful in the litigation now pending, and brings these patents to a premature end, or at all events establishes the freedom of its own instruments from their patents, there will be nothing to stand in the way of a direct competition in which the United and its subsidiary companies will be immensely handicapped." The United has made a move in promoting a company with a capital of £10,000,000, evidently with the intention of harassing Government action by-and-by, but we doubt very much if the object will be attained. There are some business heads in the Postal Telegraph Department that can give the wire-riders of this huge company a good many points without losing the lead.

NOTES.

Telephones in America. The United States has 341,970 telephones in use. The net profit from these in 1886 was 1,150,000 dollars. The extent of the wire is 128,231 miles.

French Novelties. Descriptions of a new type of arc lamp, by M. Gance, taking three amperes, and of a small pocket photometer, by M. Mascart, were read at the Societe Francaise de Physique.

Accumulators for Bremen. A very large storage battery will be provided for use in the central station at Bremen by Messrs. Spicker and Co., of Cologne, who have the contract for lighting.

Magnetic Iron-Separator.—Enquiries are made for supply of these machines, which have been exhibited in one of the exhibitions lately. We shall be glad to hear if they are manufactured for sale.

Electric Power Printing. A printer who has tried states that there is no other power to be compared to electricity for running printing presses as regards economy, cleanliness, and easy management.

Telegraph-Engineers Students' Meeting. A paper will be read on Thursday, June 7, at the students' meeting, "On Belts and Belt Driving for Dynamos," by J. N. Cooper; Prof. J. Perry, F.R.S., in the chair.

Schanschieff Battery. The Schanschieff Battery Company, Limited, have had an injunction brought against them on the ground of prior invention, and have had to suspend practical operations until further settlement.

Glass Sleepers. We understand that a company is being formed for utilising toughened glass for railway sleepers, in which Mr. Fred Siemens is interested. These should be used when our electrical tramway companies get to work.

Glass for Electric Light.—A great deal of glass work for shades, reflectors, &c., for electric light use is imported from Germany. Hirsch, Janke, and Co., of Berlin, and Campe and Co., of the same city, are two chief makers.

Eastbourne.—At Eastbourne the light is so much appreciated that the authorities are paying £35 per annum for each arc lamp of 1,000 c.p., burning up to 11.30 p.m., being at the rate of £70 or £80 per annum for all-night lighting.

Elwell-Parker. Two large additional shops have recently been built by Messrs. Elwell-Parker at Wolverhampton, with a view to meeting the increased demand for dynamos and batteries, and additional engine power is also being put down.

Paris. According to the *Moniteur Industriel*, the Compagnie Francaise d'Eclairage Electrique is to be wound up by direction of a general meeting of the shareholders held in Paris. MM. Clerk and Rousseau are nominated liquidators with full powers.

Small Dynamos. We are often asked where a small type of dynamo for experimental or research purposes can be obtained. Messrs. J. C. Hauptmann and Co., of 11, Kornerstrasse, Leipzig, supply a good type of small dynamo for these purposes.

Electric Shoeblack. An electric boot blacking machine is to be seen in New York, in which a brush is rapidly revolved in a non-rotating handle. The whirling

brush brings the shine in one-tenth the time of the old vibratory elbow method.

Paris Electrical Laboratory.—La Societe Internationale des Electriciens have asked permission of the municipal authorities of Paris to have the gratuitous use of part of the ground of the ancient Rollin College, for setting up a central electrical laboratory.

Newcastle College. The new College of Science, Newcastle-on-Tyne, is making progress, though it is not expected to be ready for some considerable time. Prof. Garnett, well known as a skilled educator and scientist, is the principal of the new college. The situation of the college is near that of the recent exhibition.

Catalogue Received. We have received the catalogue of Messrs. Robertshaw and Sunderland, Victoria Electrical Works, Halifax, containing a list of electrical requisites—bells, detectors, indicators, lamp fittings, repeater and needle instruments. A linesman's tool box, fitted with a complete set of tools necessary for electrical fitting, is also included.

Waltham Watch Company. This company has decided to introduce the incandescent light throughout its premises. The installation will be a small central station of itself, and will be one of the largest private plants in the world, comprising a total of nearly 5,000 lamps. The system selected is that of the Mather Electric Co., of Manchester, Connecticut.

Motors at Work.—Electricity is the motive-power for several establishments in Oakland, Cal. It runs a coffee mill for the New York Tea Company; moves a score of sewing machines for M. J. Keller, manufacturer; rotates an ice-cream freezer for O. C. Coiner, wiggles a sausage machine for Fred Becker, and is to give power to the presses in *The Evening Tribune* building.

Fire through Snow. The Pittsburgh Electric Railway Company, finding its line blocked with snow, ordered a large quantity of salt to be thrown along the line so as to dissolve it. The conductors, working at a difference of potential of 500 volts, were carried in wooden troughs, and the melting snow and salt speedily established a circuit between the conductors, with the result of setting fire to the troughs.

Tenders Wanted. The Poole Town Council invite tenders for lighting the borough by gas, electricity, or other means, for one or three years from 1st September next. Particulars from the Town Clerk. Also, Mr. J. Bertwistle, F.S.I., architect, Jacketts-street, Blackburn, is inviting tenders for electric light installation for new weaving shed, Ribchester, near Blackburn. Tenders must be sent by June 9.

Dangers of Gas.—A terrible explosion of a gasometer is reported from Montreal. The whole of the gas works were completely destroyed, and seven persons killed, thirty persons were injured, many seriously. A similar accident has occurred at Gorinchem, Holland, where the gas escaping caught fire, and the explosion which followed totally destroyed the purifying house. One person was killed, and three are in a precarious condition.

A Good Word for the Telegraph Wires.—A large piece of cornice in Chicago fell last week, and fortunately caught and was held suspended on the telegraph wires, and only fragments struck those underneath, who otherwise might have been killed. At a newspaper office

at Des Moines, Indiana, a fire broke out, and the workmen, who found the stairway burnt out, climbed along the telegraph wires and slid down the post, amid the cheers of the spectators.

The Phonograph.—Edison's phonograph, in its improved form, has been launched with great *éclat* in New York, and long descriptions appear in the New York papers. Mr. E. T. Gilliland, Edison's colleague in the matter, read a paper, and numerous interesting experiments were made. It is worked by a small electro-motor; the usual size will record a continuous speech of eight minutes' duration, about one thousand to twelve hundred words. The price is 85dols., and large orders are booked.

Ronard Battery.—At the Société Savantes M. le Capitaine Ronard exhibited a single fluid battery, which he claims far surpasses all previous batteries in its results and cost of maintenance. The first cost, however, is greater, the cells being of silver, with platinum thickly deposited outside. It is worked with a chloro-chromic solution. The battery is remarkable for the smallness of its weight for the work given, and also for its constancy. He proposes using these batteries for aerial propulsion in the French army.

Diamagnetism. At the meeting of the Société Savantes of May 14, M. Mascart presented some observation upon the theory of diamagnetism, brought forward by M. Blondlot, of which we gave an abstract last week, in which he said that the conclusions arrived at were not justified. M. Becquerel, however, had not the same opinion. He thought that M. Blondlot's experiments coincided with the hypothesis he had maintained since 1850 that magnetic and diamagnetic phenomena were mutually dependent.

Leamington. The lively discussion last week seems to have aroused the company to further action. It is announced that they have decided to put down a large supply of accumulators from which customers would be supplied as a protection in case of accident to machinery or dynamos. After June 1st, the supply will be continuous night and day. This will not alter the street lighting, however, of which chief complaint was made, and many persons think that a change of the kind of lamps used in the streets will be satisfactory.

Wimbledon. Notice is given in the *Gazette* of the 25th inst. of the application to the Board of Trade of the Wimbledon Local Board for a licence to supply electricity under the Act of 1882, to break up streets and railways, &c. Copies of the draft of the licence can be seen at the office of the Local Board, Broadway, Wimbledon, and at the office of the solicitor for the licence, W. H. Whitfield, Esq., 22, Surrey-street, Strand, W.C. Representations to the Board or objections must be sent to the Board of Trade within two months from 5th May, 1888.

Enghein-les-Bains. At this station, on the Northern Railway Company of France, the petroleum lamps hitherto used are to be replaced by 90 incandescence lamps worked by 160 accumulators on the Laurent-Cely system. These accumulators are to be charged by a dynamo at the works of La Chapelle, through a copper conductor 24 kilometres in length, and 5 millimetres in diameter. A French contemporary gives the E.M.F. of the dynamo as 700 volts, which would apparently render it ill-adapted for the purpose in view. The enterprising railway company above mentioned expects to realise a saving of 33 per cent. by the substitution of electric power for oil.

Zipernowski-Deri Transformers.—Since 1887 Ganz and Co., Buda-Pesth, have installed, says *L'Electricien*, a number of distributing centres, using the Zipernowski-Deri Blathy transformers, which are acting perfectly, and show the excellence of the system. At Montevideo 450 h.p. is transformed by their means, at Terni 450, at Rome 1,200, at Livorno 450, at Saint Paul 300, and at Odessa 300. The station at Rome consists of two alternate current machines of 600 h.p. each. Several further installations have also been undertaken this year. These transformers are spreading more and more in practical use.

Electric Launches. The propelling of boats by electricity is receiving quite a boom in Massachusetts. The Electric Accumulator Company is in daily receipt of many inquiries of this nature, and has just installed an accumulator plant, to be used with a small Sprague motor, in a rowboat at Attleboro', Mass., belonging to H. K. Sturdy. The same company has also fitted the beautiful new yacht "Sagamore," belonging to John W. Streeter, with an accumulator plant, to be used in connection with the Edison system of incandescent lighting. The yacht was built by the New England Shipbuilding Company, and is shortly to start on a cruise around the world.

Amsterdam. The central station of electric lighting now actually at work at Amsterdam presents certain interesting features. The station being situated very near the places to be lighted, the engineers have passed over the high potential system and alternate current system, and instead have adopted the system of distribution at 100 volts. The current is furnished by two dynamos driven at 100 revolutions only per minute, by a direct driving steam engine of 340 h.p., by this means obviating any risk of stoppage from gearing or belts. In addition, the attendance required is very small. The installation has been carried out by the Helios Company of Cologne.

Telegraph Clerks. The seventh annual conference of the United Kingdom Telegraph Clerks' Association was held in Leeds on Saturday, delegates being present from all the large provincial offices. The financial condition of the association was reported to be in a much improved state. By a special resolution, the insurance subscription was reduced from sixpence to twopence per week. A resolution to petition the Postmaster-General on certain grievances was negatived, it being considered desirable to wait the result of the Civil Service Inquiry. The system of annual leave was declared unsatisfactory. The conference supported the Sunday pay agitation.

Dust on Electric Wires.—The accumulation of dust on electric light wires is explained by Mr. G. A. Nellis as follows:—The magnetic whirl round an electrical conductor acts upon the atmosphere, which is highly magnetic, oxygen being the most paramagnetic nitrogen, and the most diamagnetic of gases. The attraction of the oxygen will cause some of the dust to adhere to the wires; the repulsion of the nitrogen will cause the ceiling near to be blackened. This accumulation of dust is more noticeable on the positive wire of a continuous current system, and is absent on a wire conveying an alternating current, which may be thus easily distinguished by its comparative cleanliness.

Hamburg Central Electric Lighting Station.—The firm of Mr. S. Schuckert, of Nuremberg, has been entrusted by the State of Hamburg with the installation of the Hamburg Central Electric Lighting Station, for which about 24 prominent firms had tendered. This central station is intended to supply about 20,000 incandescent

lamps, and an enlargement is in contemplation. During the course of this year a first installation of 10,000 lamps must be completed. According to the calculations issued by the experts of the Finance Committee, it is expected that the undertaking will prove a financial success, 6 per cent. on the capital invested being the estimated net profits.

M. Desroziere's Dynamo.—At the Societes Savantes M. Desroziere exhibited a dynamo on which he has been engaged for some years at the works in Bréguet. It is of the disc type, the advantage of which is great linear speed of revolution, avoidance of loss of work in alternations of magnetism in the field-magnets; the conductors are bare and well ventilated, and yield a very large current per unit of section. M. Desroziere gave figures which showed a produce of 14 amperes per square millimetre, which is enormous compared with ordinary types, these rarely yielding over six. The air space in this machine was considerable. Allowing for clearance of the armature, nevertheless, the field obtained was nearly 10,000 units.

Accumulator Tests. The tests undertaken by the Electrical Institute at Venice by Prof. von Walden hofen have now terminated. They were instituted to try the merits of various accumulators made by Fahrbaky-Schenk, Reckenzaun, and Julien, especially with regard to their application to tramcar work. Tests were taken of the E.M.F. on open circuit, the density of the fluid, and the difference of potential during work. The comparative efficiency of the batteries is as follows: Reckenzaun, 89.3 per cent. return of quantity, 80.85 per cent. of the total energy, calculating difference of potential, charging and discharging; Julien, 89.7 and 83 per cent. respectively; Fahrbaky-Schenk, 91 and 78.5 per cent.

Carbon Factory. One of the most important carbon factories is Mr. Th. Schmelzer's at Nuremberg, established in 1884. Since its commencement the undertaking has been remarkably prosperous, and at present about 75 workpeople are employed. After many costly experiments, Mr. Schmelzer has succeeded in constructing most efficient pressing machines, especially hydraulic pressing machines, working with a normal pressure of 600 atmospheres, and the machines now in operation are capable of producing 25,000 meters of carbon rods per day. Two gas generators furnish the gas for two furnaces, which comprise about 30 cubic metre available space in 10 compartments. The factory is lighted by 20 arc lamps, fed by a Schuckert dynamo.

Automatic Leak Indicators. In his paper on "Installation Breakdowns," read before the Old Students' Association, which we reproduce this week, Mr. Reginald J. Jones makes a suggestion which we think may possibly be worthy of further and practical consideration. He mentions the fact alluded to by Mr. Crompton, that an installation whose insulation resistance is very high, after actual use often deteriorates considerably in this respect. Mr. Jones suggests the permanent presence in the circuit of what he terms an automatic leak detector, which shall give prominent notice, by alarm bell or other method, when the insulation resistance falls below a certain point beyond which the leakage might endanger the system. We shall be interested to see whether this original suggestion will be carried out.

Central Station at Paris.—The Paris Compagnie Parisienne d'Eclairage Electrique, whose central station is installed at the Place du Pantheon, are proceeding to public trials to learn if they may distribute the light in the

Quartier des Ecoles, where it has been opposed for some time. The installation at present comprises three "Brown" dynamos, 110 volts, and 360 amperes, with a speed of 360 revolutions per minute. Each of these dynamos is driven direct by a quick speed steam engine. Collet boilers are used. A main switch board, well grouped and easily supervised, allows a regular light to be assured. All the material has been installed so rapidly that the machinery had only to be placed in position, everything being sent mounted and ready to work from the works of the (Erlikon) Company, near Zurich. The Sainte Genevieve library will be shortly lighted.

The Distribution of Motive Power.—This application of electricity is more or less general among the central stations of America, by the use of electro-motors, not only for ventilating, knife-cleaning, &c., but also for heavier work, such as printing. The employment of small electro-motors for domestic use does not seem to have received such a development as might be expected in this country, though no doubt when central station distribution for light is more general, these will be used. At Salzburg the employment of electricity for use with motors in the daytime is greatly extending, many motors of the Siemens' type giving $\frac{1}{2}$ to 1 h.p. have lately been put in. These work at a speed varying from 1,200 to 2,500 revolutions per minute, and are used for ventilating kitchens and billiard-rooms, and for various domestic purposes.

New Filament from Russia. We notice an account from Pittsburgh, U.S., of a visit from M. de Routhowsky, secretary of the Russian Legation, to Mr. Geo. Westinghouse, jun., to bring before his notice a new filament invented by a fellow-countryman, on whose behalf he has concluded an important contract with Mr. Westinghouse relating to incandescent lamps. The discovery relates to a filament that is capable of standing so high a temperature as to give two to four times the light with the same power as the Westinghouse or Edison lamps. It is said the filament will give more light for the horse power than two arc lamps, and it is hoped to be used instead of arc light systems. The effect on incandescent lighting would be to double the capacity of existing plants, while saving 10 per cent. in fuel. If Mr. Westinghouse has taken the matter up we may expect to hear more of the discovery—meanwhile rumour requires confirmation.

Electric Tramways. A letter from Lord Bury appeared in the *Birmingham Daily Post* of the 26th ult., in which he says that electricity as a motive power for tramways is not, as a correspondent imagines, "a pleasant vision and a vision afar off," but that it may be seen in actual operation by anyone interested in the subject at Canning Town, London. Lord Bury is chairman of the Electric Traction Company, New Broad street House, which has a contract with the North Metropolitan Tramways Company for working a portion of their line experimentally at first, and afterwards to be extended to the rest of their system. The experimental car is now at work with complete success, and he invites persons interested to inspect the system. He states that they are prepared to equip tramways, which in point of economical working will compare favourably with horses, and that the system is in actual operation, and suggests that the vision, however pleasant, is not a distant one.

Mouldings. Not the least important question where artistic electric lighting has to be considered is that of mouldings for the wood casing containing the wires. Of

course, in running the conductors for an installation, it is quite easy to bring in hundreds of yards of ordinary white wood moulding and run it, *a tort et a travers*, all over the building, but in a good house it is often very necessary to consider the decorative effect of the moulding where the wires are run, so that they may be both harmonious with the surroundings, and not noticeably prominent. Considerable attention to this detail of electric lighting has been given by Mr. F. Geere Howard, Cleveland street, W., and we have also lately received a very well got up pamphlet from Mr. Samuel Elliott, Albert Moulding Works, Newbury, containing sections of high class mouldings suitable for this purpose. The pamphlet contains some five or six hundred designs of mouldings, plinths, cornices, picture rails, &c., from which, in fitting a house, electrical engineers might select to suit the requirements.

Windmill Electricity. The idea in America of utilising wind power by the aid of storage batteries for the purpose of light, heat, and power is very soon to be put to a practical test in a building about to be erected in Minneapolis, U.S. A windmill capable of giving 10 h.p., with a fifteen mile breeze, will be fixed on the tower, and connected to a dynamo, which will charge accumulators when the wind blows above a certain rate. A recording wind pressure gauge, and a recording voltmeter will be provided to show at any time what has been put into the batteries, and a recording amperemeter will be connected in the circuit to show what has been taken out. The plan as described is quite feasible, and its fulfilment is watched for with a good deal of interest at the locality that their frigid nor'-westers may be turned to some account towards diminishing instead of increasing the gas and coal bills. It may be mentioned that Prof. Blythe, of Glasgow, has successfully used wind power for driving dynamos to charge batteries, as also have the French authorities.

Fires from Electric Wires. There have been quite a large number of cases of fire caused by electric light wires reported from America, the Lotus Club and the offices of the *American Magazine* both having a near escape. Mr. Heaphy, of the Phoenix Fire Office, has insisted on a much higher class of installation work in this country, and to the stringent precautions generally adopted here we must give credit for our immunity from these accidents. The same comparative slovenliness that characterises the running of American street electric light cables, railway tracks, and motor car cables, will no doubt lead to similar workmanship being employed interiorly in establishments where a slight accident can cause a great deal of damage. With all the advantages the Americans can claim, of quick workmanship, of "rushing," and "booming," the advantage may be bought very much too dearly if it leads, in a comparatively large percentage of cases, to liability to fires, and we should advise those in superintendence to insist on the most careful precautions against fire risks in their country, such as are now happily quite the rule in England.

Vacuum in Lamps.—The proposal has several times been made to prepare incandescent lamps with a filament which will need no vacuum. Independently from the difficulty or impossibility of getting a filament which shall fulfil the requirements of such a lamp, some experiments of M. Cailliot go to show that the absence of the vacuum, if one may use such a phrase, is by no means desirable on the score of efficiency of the light. M. Cailliot has found, when he has experimented with heating of wires by the passage of electricity under different pressures, that the heating

effect decreases as the pressure increases. A current that will melt a wire of a certain thickness under ordinary pressure will only raise it to a dull red heat when surrounded by a high pressure. This would point out the superiority of lamps with a high vacuum over those filled with a neutral fluid, or with air when furnished with an incombustible filament. American circles are agitated with a report of a new Russian filament, said to be taken up by Westinghouse, which will stand twice the ordinary degree of incandescence without failure. Granting that such a refractory substance were discoverable, and was perfectly incombustible, M. Cailliot's experiments still show the advantage of the vacuum.

The Aid of Photography. Seeing that the profession of electrical engineering is a practical one, far more than a literary or theoretic, all those extraneous means of aiding or advancing the practical issues of the business should be resorted to by those working in its ranks. As an aid of this kind, photography has begun to take its place in workshops, as the type-writer in literary offices, and to an enterprising young engineer, the knowledge of its uses and practical acquaintance with the methods of photography would be much better worth acquiring, as a rule, than other side branches of learning often taken up, shorthand for instance. Many large engineering works now keep their own photographic apparatus for use in sending descriptions, cataloguing, obtaining orders, or keeping particulars of special manufactures, and for anyone with a little spare time at his disposal it is both a pleasant and interesting occupation. Messrs. Lancaster, of Birmingham, are pioneers in cheap sets of photographic apparatus. Mr. Mayfield, late manager to Mawson and Swan, of Newcastle, gives attention to this branch as much as to electrical accessories. The Stereoscopic Company supply sets, and give instruction free to purchasers, and there are some admirable classes at the Polytechnic, Regent-street.

Overhead Wires in New York.—Not a little excitement has been caused in New York by the finding of the verdict by the jury investigating the death of Meyer Streiffel, a lad who was killed on April 15 by a shock from an electric light wire. Dr. Otto A. Moses gave evidence as to danger of high tension currents, and stigmatised overhead wires as "a perpetual menace to human health, and a constant danger to human life. In Europe," he said, "the overhead system would not be tolerated one instant." In a case of general breakage at a fire, Dr. Moses said there would be much danger. After an hour and a half's deliberation, the jury found that the death was due to the neglect of the United States Illuminating Company in not removing the loose wire, which was shown to have been hanging there for more than four weeks, thereby endangering the life of the public. The *New York Herald* organised a commission, consisting of an electrician, a photographer, and a reporter, to investigate the state of the overhead wires, and publishes many columns reporting upon the same, calling attention to the fact that, bad as it has been believed, it was nothing to the real state of the case, wires of all kind being mixed up indiscriminately, with promise of utmost danger in case of fire or accident, and concludes that "the wires will have to be put underground, or else many of the public will."

The Electric Light in Another Newspaper Office. There is, according to the *New York Electrical Review*, a very complete electric light plant in the new building of the *Post Dispatch*, St. Louis. The dynamo is of the Edison

standard type. The capacity of the dynamo machine is 300 16-c.p. lamps, while the feeders and mains of the wiring system are proportioned for 600 16-c.p. lamps, which provides amply for the anticipated increase to 500 lamps of 16-c.p., or 400 lamps of 20-c.p. Since the dynamo is expected to give almost continuous service, the belts are so arranged that power may be had from either the Corliss or high-speed engine. The dynamo is also provided with a substantial brick and cement foundation surmounted by the wooden base frame necessary for insulation. On this wooden frame the side rails are securely bolted, the dynamo being held in position by its own weight in connection with the grooves into which the slide rails fit to keep pulleys in line. The net weight of the dynamo is 2,880 lb. The floor space occupied 66 by 50 in.; the height above base of frame 4 ft. The diameter of pulley, 12 in.; revolution of armature per minute, 1,400. The 25 h.p. required to drive armature when under full load is transmitted by a light double endless Schultz belt. On the side wall, in position most convenient for the engineer, are found the regulator, the pressure indicator, the ampere-meter and the ground detector.

Lighting in America.—The following are some of the numerous items of new plants and extensions in America:—San Francisco is to have another large station, with a capacity of 1,000 arcs, and a goodly number of incandescents; in New Jersey the Edison Company have a contract for a central station of 2,500 lights at Sea Isle City; Sing-Sing, New York, is to have a large central plant; Hagerstown, Md., has 100 arcs and 1,200 incandescents; Knoxville, Tenn.; Robertsville, Conn.; Santa Ana, California, are lighted; Greenville, South Carolina, is to have 60 arcs and 400 incandescents. Under the United Company many central stations are being installed. Among others may be mentioned Freehold, N.J.; Jackson, Ohio; Greenville, Miss.; Charlottesville, Va.; Laredo, Tex.; Oswego, N.Y.; Cooperstown, N.Y.; Fulton, N.Y.; Massillon, Ohio; Chetopa, Kansas. We may mention, also, in the way of isolated plants, the Averne Hotel, at Rockaway Beach, to have a 400-light plant; Omaha and Grant Smelting and Refining Company, Omaha, Neb.; Marshall Saw Mills, Marshall, Cal.; Tivoli Opera House, San Francisco, Cal.; San Francisco Cordage Factory; Los Angeles College, Los Angeles, Cal.; Puget Lumber Company's Mill, Port Ludlow, Washington Territory. New York City has asked for tenders for lighting the city streets with some 400 arc lights. These are a few out of numberless items with which the American papers teem. Matters seem to be pretty brisk with electric lighting over there.

Eccentricities of Lightning. The following letter appeared in the *Times* of May 26:—"Sir, The case mentioned in your impression of to day of three persons sitting together, the two outer ones being killed by a stroke of lightning while the middle one escaped, is known to electricians. Arago (*Annales* for 1838) and others have recorded many examples. On the 2nd of August, 1785, lightning struck a stable at Rambouillet, where 32 horses were ranged in a line, side by side; the two outer ones only were killed. On the 22nd of August, 1808, a house at Knonan in Switzerland was struck. Five children were sitting on a bench in a room on the ground floor. Of these the first and last were killed on the spot, while the others experienced only a violent shock. In 1801 lightning fell on a windmill near Chartres, and set it on fire. The miller was approaching the mill between a horse and a mule, both laden with corn; the two

animals were killed on the spot, while the miller escaped with a severe shock. In attempting to explain such facts, Arago instances the case of a bar of metal struck by lightning, which was apparently not much damaged, except at the spots where it made its entrance and its exit, so that in the above cases the intermediate bodies simply transmitted the charge. Many cases are cited to show that human beings resist the effects of lightning more powerfully than the lower animals. It is difficult to generalise on such cases as the above, however numerous they may be, seeing that we sometimes meet with exceptional cases. The following was related to a nephew of mine, while vicar of Denchworth, near Wantage. On the 9th of June, 1832, a woman, Martha Warman, was walking from Wantage in company with two men, she occupying the middle place, when about 1.30 p.m. they were struck by lightning and fell to the ground. The men soon regained their feet, but the woman was dead: her face, body, and clothes were cut and torn, her stockings set on fire, and her boots much rent. But seeing the curious way in which lightning picks out bits of metal, it must be noted that she had been carrying an umbrella, she wore steel in her stays, and had wire in her bonnet, which was fused and twisted. A cross by the wayside still marks the spot.—I am, &c., C. TOMLINSON, F.R.S. Highgate, N., May 24."

South Kensington.—The official report of General Festing, R.E., upon the electric lighting at South Kensington Museum showed good things for the electric light. General Festing stated that the cost under the new lighting last year was £1,224; the cost of the same lighting with gas would be £2,845—a saving of £1,621 in favour of electric light. These figures seem to need some comment, as it is hardly likely that if it were quite clear that a saving of more than half were effected, and that the same could be expected from every public institution, so few public galleries would have been lighted. There are galleries and galleries, and at those where the gas lighting itself might be considerably reduced with a different disposition of gas jets, electricity, of course, has by far the better field before it. In galleries centrally lighted, where the disposition of the gas jets has been carefully attended to, and the greatest possible effect from gas obtained, it is well known among electrical engineers that it is not always possible to prove an advantage on the score of cost, and it is generally upon the distinct benefit from absence of heat and of dirt that the electric light has been adopted. But this favourable disposition of gas is not always present. In many galleries there are long lines of flaring gas-jets down each side of the room, sometimes containing many hundreds of burners, placed high, to be rid of fumes or scorching, and therefore, seeing that light varies as the square of the distance, considerably extravagant. It is these places where we can best see the way to advocate the electric light on the score of cheapness, as well as of cleanliness. One gallery in Bond-street, hitherto lighted with double rows of gas-pipes, containing 120 burners, is now lighted with 12 or 14 incandescent lamps of 50 c.p. quite as effectively, if not more so, than with the gas. The additional advantage is also found of immediate light being obtainable by the motion of a switch handle, instead of the troublesome method of lighting a taper and proceeding gradually around to light the rows of burners while the gas is escaping. We commend the serious consideration of the South Kensington report to the principals of the National and other galleries.

ARTISTIC FITTINGS.

II.—FARADAY AND SON.

At the time of the first development of the incandescent electric lighting in this country after the historical lectures

that the beauty of the lamps called forth was due to the attention that Messrs. Faraday and Son gave to the graceful appearance of the special fittings there used. Having a large connection among public institutions and West End private individuals, this firm were in a position to gauge the necessities of the occasion, and enterprising enough to throw

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 5.

FIG. 6.

FIG. 7.

of Mr. J. W. Swan, and the exhibitions of lighting at the Paris and Crystal Palace Exhibitions, apart from the scientific interest of the invention, not a little of the interest

themselves came into the breach now provided for the introduction of suitable fittings for the new light. In many places at first nothing seemed to be thought of the

the adaptation of existing gas and oil fittings to the wires of the incandescent lamp, but it was soon recognised that the character of the light was essentially different from that of gas, that appearance practically was all that need be considered, the lamps being adaptable to any situation and position. A much lighter form of fitting then became the desideratum, and those light elegant floral designs originated by Faraday's were speedily adopted. The now almost universal tulip or lily glass,

FIG. 7.

like the petals of a delicate flower, blown in blue or straw opal glass, was originated in this firm's show-rooms, and was the outcome of mutual deliberations of Mr. Alfred Waterhouse, F.R.I.B.A., the well-known architect of the

FIG. 8.

Law Courts, &c., and Mr. Harold Faraday, and was rapidly adopted wherever the incandescent lamps came in use. When Mr. J. W. Swan gave the first lecture before the

Royal Institution and at the *conversations* at the Royal Academy, the fittings were designed specially by this firm,

FIG. 9.

FIG. 10.

and also for the before-mentioned Paris Exhibition, where the memorable display of the first patented Swan lamps was brought before the world, and at the exhibition of

Messrs. Siemens and Swan at the Crystal Palace. Simple and elegant, or rich and elaborate, the light lends itself easily to either treatment, and we give illustrations this week of some of the more noticeable and novel designs of artistic fittings designed and made by Faraday and Son. The specialty of the firm seems to be that of brasswork in all its forms—polished, and gilt or silvered, in airy and elegant shapes, as distinguished from the more ponderous of some other forms of fittings. Not a little of this effect is due to the special holder, named the "Sydenham Holder," of which we give an illustration (Fig. 1). It is made in pierced brasswork, of a shape that fits and carries out the lines of the lamp globe, and enables the lamp itself—ground glass or plain—to be fitted in beauty unadorned in many cases most effectively, a result hardly possible with the old forms of outside wire springs, or large metal cases. The fittings, Figs. 2 and 3, show this; one is a simple little standard for a piano, to be connected with a flexible cord to the wall plug, and moved about on the piano. The arm is jointed, the joint being a concentric contact of two brass spheres, is not liable to short circuit. Fig. 3 is a very useful little pendant with a white porcelain ribbed reflector, behind which the lamp is hung for use in front of pictures, or in shop windows, or any position in which the light is required to be guarded from the eyes and thrown in front. The centre of gravity is shifted by means of the wire arm, so as to cast the reflector forward as shown.

A very pretty design is shown in Figs. 4 and 5, which Messrs. Faraday have made their own. Filigree work of hand hammered flat brass in little curls surround the opal glass inside which the lamp is fixed. It is suspended on flexible cord, which is often variously adorned with beads, or rings, or knobs of Eastern wood, or turned in brass. Sometimes these pendants are oxidised in antique patina bronze, to increase the Oriental effect. The parachute pendant, Fig. 6, is a useful and very ornamental little fitting: a silk shade with fringe shades the lamp, and the flexible attachment is coiled on a spring drum, which allows it to be raised or lowered by slight pull of the cord in the manner of the patent blinds. Messrs. Faraday make several patterns of ornamental counterweight pendants with cords and pulleys. An adjustable pendant invented by Sir David Salomons, and named by him the "Perfect" pendant—a great favourite in installations, being universally adjustable—has three cords of attachment, which run over separate pulleys, so that, besides motion up and down, it can be tilted, and will remain pointing in any direction. This fitting is very useful both for ladies' dressing-rooms (where very particular and artistic operations must be performed) and also for drawing offices, as it can be raised or lowered and shaded from the eyes. The fittings illustrated by Figs. 7 and 8, the floral and eschiline brackets are of hammered copper, or copper and brass mixed, of a leafage or floral design, and are very effective in certain positions, the warmth of the reflection of the polished copper being harmonious and soft. A handsome electrolier is illustrated at Fig. 9, selected out of several various and equally artistic designs suitable for use in large drawing rooms or similar positions. It is in wrought and turned brass work, chased by hand, leafage in decorated *repoussé* work, with engraved arms, and with filigree brass work crowns to fit the cut-glass pine-shaped shades. These electroliers are also very effective when finished, as is often the case, in antique oxidised silver, and with crimson suspending cords. Of standards of all kinds for offices, writing tables, drawing-rooms, and bedrooms, there is a large variety. We illustrate one a little out of the common, Fig. 10. The stand is a sculptured mask, with Renaissance decoration, and bears a silk shade with lace fringe, and is very suitable for a lady's boudoir or drawing-room.

THE EFFICIENCY OF INCANDESCENT LAMPS WITH DIRECT AND ALTERNATING CURRENTS.*

BY W. E. AYRTON AND JOHN PERRY.

It is now well understood that in order to economically distribute power by means of electricity, it is necessary to

employ a high potential difference, or P.D., between the mains and a small current flowing through them; while considerations of safety require that the P.D. between the leads in the houses shall not exceed 100 or 200 volts. Hence, some system of converting a large P.D. and a small current into a small P.D. and a large current has to be employed, and the four systems of conversion that have hitherto been devised consist in the employment of—(1) motor dynamos, (2) accumulators, (3) alternating current transformers, (4) direct current transformers.

Of these four methods, the third is the one that is most extensively utilised at the present time; indeed, it is the only system of conversion that is at all extensively used, at any rate in this country. But in view of some direct current system of conversion coming also into common use, there arises a question of considerable importance to the consumer—viz.: Is more light obtained with the same expenditure of power with direct or alternating currents? And, apart from considerations of the electric distribution of power on a large scale, the answer to this question is of importance in supplying one factor towards the decision as to the relative advantages and disadvantages of direct and alternating currents for detached installations.

Where the electric energy supplied to a consumer has been charged by meter, people have, as a rule, been content to measure only the number of coulombs supplied, ignoring altogether any variation in the volts; but as electricity *per se*, apart from the P.D., is of no commercial value whatever and, therefore, is unlike water apart from pressure—it is clear that in estimating the value of a supply of electric energy we must measure the watts, and not merely the current. The problem, therefore, that we have attempted to solve is whether a Board of Trade unit (1,000 watt-hours) is more valuable for lighting by incandescent lamps when the current is direct or when the current is alternating.

For a complete solution of the problem we must ascertain not merely the "efficiency of the lamp" or number of candles per watt with the two systems of supply, but also the life of the lamp, since the cost of lamp renewals may be as important a question for the consumer as the bill for electric power. Unfortunately, however, there does not exist, as far as we are aware, any accurate information as to the life of an incandescent lamp with various alternating P.D.s. Indeed, the data at our disposal for the life of a lamp with various non-alternating P.D.s. is most meagre; and if any member of the society can supply us with any information regarding the life of some fixed type of incandescent lamp, either with different direct P.D.s. or with different alternating P.D.s., we shall be grateful for the information, as it will furnish us with a further opportunity of using the method described in our paper read before this society for deciding "On the most Economical Potential Difference to Employ with Incandescent Lamps."

For the present, therefore, we shall confine ourselves solely to the question of efficiency, and, as it is known that the efficiency of an incandescent lamp is increased with the current passing through the lamp, it is clear that to obtain an accurate comparison of the efficiency with direct and alternating currents, we must employ exactly the same current in both cases, or rather the same mean square of the current, for this will be most likely to develop the same rate of production of heat in the lamp, since this rate is proportional to the resistance into the mean square of the current, whether the current be direct or alternating. We say most likely, because it must not be assumed without experimental proof that the resistance of a filament is exactly the same for the same mean square of current, whether that current be direct or alternating.

Some writers have stated that the current, as measured by an electro-dynamometer, required to be sent through an incandescent lamp, when emitting a definite amount of light, had a different value, when the current was an alternating one, from what it had when the current was direct. This difference might be due either to a defect in the dynamometer measurement, or to some variation in the light standard. If the wire with which the dynamometer is wound be thick, then the current density may be far from uniform when the current is alternating; and on this account, as observed by Captain Cardew some years ago, a

In all the experiments the plane of the filament was perpendicular to the screen.

dynamometer might give different readings for different rates of alternation, while an incandescent lamp in circuit remained equally bright.

To avoid this possible source of error, the dynamometer which was constructed by Messrs. Shepherd, Vignoles, and Wheatley (the three of the students of the Central Institution who carried out the investigation) was wound with much finer wire than would usually be employed in the construction of a dynamometer not required to read currents much below one ampere. The dynamometer was for that reason unnecessarily sensitive, and it required a fairly strong spring to control the motion of the suspended coil. This led to an unnecessary waste of energy in the dynamometer, but that was of no consequence in this investigation, as our object was to measure the mean square of the current most accurately, and not to satisfy the condition, which is of considerable importance in the design of commercial measuring instruments, of wasting as little energy as possible in the instruments.

To the suspended coil of the dynamometer was attached a mirror, and the values of the deflection of the spot of light were determined by direct comparison with the simultaneous readings of an accurately calibrated spring ammeter when various direct currents were sent through the circuit. The sensibility was such that a deflection of 100 scale divisions was produced on a scale 68.88 inches away for a current of 2.53 amperes, which corresponds with a deflection of 110 scale divisions for 1.5 amperes, which was about the usual current passing through the dynamometer in the actual lamp experiments. The values of the current could,

therefore, be accurately measured by the dynamometer, which is indicated by D in the figure, and then, by knowing what fraction of the current passing through the dynamometer, D, passed through the non-inductive voltmeter, V, the current passing through the lamp is known.

Any error that might have arisen from a variation of the light standard was eliminated by taking successive readings with a direct current produced by a Gramme dynamo, G, and with an alternating current produced by a Ferranti dynamo, F, the switches, S and s, being turned to 1, 1 in the first case, and to 2, 2 in the second. The Gramme dynamo was also used to excite the field-magnets of the Ferranti, a suitable current being obtained by a proper adjustment of the resistance, p. By means of the resistances, q and l, the direct and alternating currents passing through the incandescent lamp, L, could be respectively varied; and it was found that if the resistances were so adjusted that the reading on the dynamometer, D, was the same in both cases, so also was the reading on the non-inductive voltmeter, V.

It is known that when power is supplied by means of an alternating current to a circuit of resistance, r, ohms and coefficient of self-induction, l, secohms that

$$\text{Number of true watts} = \frac{r \tau}{\sqrt{l^2 \pi^2 + r^2 \tau^2}}$$

where the measured watts were obtained by multiplying $\sqrt{A^2}$, the square root of the mean square of the amperes as measured by the dynamometer, by $\sqrt{V^2}$, the square root of the mean square of the volts, as measured by the non-inductive voltmeter, and where τ is the time between one alternation and the next, or half the periodic time. Therefore the

$$\text{Number of true watts} = \frac{r \tau \sqrt{A^2 V^2}}{\sqrt{l^2 \pi^2 + r^2 \tau^2}}$$

where in our case r and l are the resistance and co-efficient of self-induction of the carbon filament of the lamp. In the first set of experiments a lamp with a looped filament was employed, but the experiments seemed to indicate that the value of l was not quite small enough to make the term $l^2 \pi^2$ absolutely negligible, or else that there was some slight mutual induction between the dynamometer coils and a small brass vessel containing oil, in which moved a damp-

ing vane, attached to the moving coil. The results were therefore discarded, and this vessel was removed and replaced with one made of non-conducting material, and all metal near the dynamometer was, as far as possible, removed. The lamps subsequently employed were, first, one with an M shaped filament, and another with a simple horseshoe-shaped filament, each possessing little self-induction.

The light was measured by comparison with a standard candle, the two being placed 130 centimetres apart on the photometer, P, and a screen, composed of two pieces of paraffin wax, W, with silvered paper between them, was adjusted until the two pieces of wax appeared equally bright, the comparison being first made when the screen was looked at through ruby red glass, and then through signal green glass.

The following is a sample of the results obtained, *a* and *b* being the distances respectively of the screen from the incandescent lamp, and from the standard candle :

It will be observed that in the set of four successive observations given in Table I. for green light, the candle-power of the lamp appears to be steadily increasing, a result probably due to the brightness of the candle slowly diminishing, but although this would make the absolute determination of the efficiency of the incandescent lamp inexact, it introduces no error in the determination of the relative efficiencies of the lamp with direct and alternating currents, since every observation with the direct current was immediately followed by one with alternating current, so that the means of all the corresponding direct current measurements may be safely compared with the means of all the alternating current measurements. Similarly, it is unimportant whether the standard candle used on one day was slightly more or less bright than the standard candle used on the following day. Further, since for any two successive observations with the same coloured light with direct and with alternating current, the screen was at practically the same distance from the lamp, the fact that the rays of light coming from the lamp made a somewhat different angle with the surface of the paraffin wax from the angle made by the rays coming from the candle introduced no error in this investigation of comparative efficiencies, although it might very likely do so in the absolute determination of the efficiency of an incandescent lamp. In fact, the simple device of successively taking observations with direct and with alternating currents throughout the whole investigation, removed most of the objections that usually may be made against photometric determinations carried out with a candle as the standard of light.

Disregarding the experiments made with the lamp with the looped filament for the reason given above, Table II. gives the summary of the results obtained ; and the conclusion to be drawn from them is that although the watts per candle for green light are not quite the same for direct and for alternating currents, and although the watts per candle for red lights are also not exactly the same for direct and alternating, still the difference between the results is so small that it may be put down to experimental errors, and this, combined with the fact the mean of all the 75 experiments gives practically the same number of watts per candle for both direct and alternating currents leads to the practical certainty that the efficiency of an incandescent lamp is the same for both direct and alternating currents.

A SMALL SELF-REGULATING DYNAMO.

Our illustration represents the improved self-regulating dynamo of small size built by the Waterhouse Electric and Manufacturing Co., of Hartford, Conn. It will be remembered, says the *Electrical World*, that the regulation of these machines is effected without shifting the brushes. It will be noticed that there are three brushes on the commutator—the two main brushes and an auxiliary brush. The current from the auxiliary brush passes to the lamp line outside of the field magnets, and the current from the upper main brush passes around the field magnets and then joins the current from the auxiliary brush, and the sum of the two is the current passing to the lamps. At the instant of

cutting out lights, the current from the main brush decreases while the current passing from the armature by way of the auxiliary brush increases, but this increase is in like proportion to the decrease of the main current, and the current on the lamp line, which is the sum of the two currents, remains normal. This balance, which, it is true, seems difficult to conceive in practice, is yet vouched for to take place in the machine, so that its operation is perfectly automatic. The new machine has been further improved by the addition of a new brush holder, and the commutator is composed of drop-forged copper segments. The groove near the rim of the pin prevents any oil from saturating the floor, and the slides, with adjustable bolts, insure a tight

The Waterhouse Dynamo.

belt. The dynamo illustrated is furnished for plants of 3, 5, 10 and 12 arc lights, and for incandescent plants of 30, 50 and 100 16 c.p. lights.

SHORT SERIES SYSTEM CONDUIT.

We have recently referred to Prof. Short's system of using electricity for traction purposes. The accompanying figure shows a section of the conduit he uses, but, fortunately for the electrical engineering industry in America, in the

Prof. Short's Conduit. Section.

smaller towns our cousins seem to have no great objection to the use of overhead conductors, which are less expensive and less troublesome to maintain.

MAGNETIC QUALITIES OF NICKEL.*

By J. A. EWING, F.R.S., Professor of Engineering, University College, Dundee, and G. C. COWAN.

The experiments described in the paper were made with the view of extending to nickel the same lines of inquiry as had been pursued by one of the authors in regard to iron (*Phil. Trans.*, 1885, p. 523). Cyclic processes of magnetisation were studied, in which a magnetising force of about 100 c.g.s. units was applied, removed, reversed, again removed, and re-applied, for the purpose of determining the form of the magnetisation curve, the magnetic susceptibility, the ratio of residual to induced magnetism, and the energy dissipated in consequence of hysteresis in the relation of magnetic induction to magnetising force. Curves are given to show the character of such cycles for nickel wire in three conditions: the original hard-drawn

* Abstract of a paper read before the Royal Society, May 17.

state, annealed, and hardened by stretching after being annealed. The effects of stress have also been examined (1) by loading and unloading magnetised nickel wire with weights which produced cyclic variations of longitudinal pull, and (2) by magnetising while the wire was subjected to a steady pull of greater or less amount. The results confirm and extend Sir William Thomson's observation that longitudinal pull diminishes magnetism in nickel. This diminution is surprisingly great. It occurs with respect to the induced magnetism under both large and small magnetic forces, and also with respect to residual magnetism. The effects of stress are much less complex than in iron, and cyclic variations of stress are attended by much less hysteresis. Curves are given to show the induced and residual magnetism produced by various magnetic forces when the metal was maintained in one or other of certain assigned states of stress, also the variations of induced and residual magnetism which were caused by loading and unloading without alteration of the magnetic field. Values of the initial magnetic susceptibility, for very feeble magnetising forces, are stated, and are compared with the values determined by Lord Rayleigh for iron, and the relation of the initial susceptibility to the stress present is investigated. The paper consists mainly of diagrams, in which the results are graphically exhibited by means of curves.

LITERATURE.

A Pocket-Book of Electrical Rules and Tables for the use of Electricians and Engineers. By JOHN MASON, C.E., and ANDREW JAMIESON, M.I.C.E., F.R.S.E. Fifth Edition Revised. [London: Charles Griffin and Co.]

When a book of this kind has reached a fifth edition in less than four years, and when the preface to each edition refers to corrections and additions, the interest of the critic is apt to flag, and his work becomes a mere monotonous repetition of the fact that "another edition has been issued." There is one use of such a work as this which is too often overlooked, that if generally adopted, as this evidently is, it consolidates our notation and nomenclature, and tends to stop the vagaries of ambitious authors from framing a notation for themselves. The authors of the pocket-book, however, should be careful to accept and define terms which are practically adopted—such, for example, as "impedance," and other terms suggested by Mr. Oliver Heaviside, and generally used by authors. Magnetic permeability, again, does not find a place, or we have failed to find it. The authors who excel in compiling this kind of work have not only the ability to decide what is useful from among the common property of engineers, but also the prescience to foresee what is at the moment only in the air, yet in the near future will be accepted by the profession. The first editions are not expected to be complete, but as time goes on, and new editions are issued, the corrections and additions should become microscopically small. It is impossible to enter into detailed criticisms. We know the book, and have used it constantly since the first edition appeared, and always with satisfaction. Still, there are some alterations or emendations that in our opinion might be made—principally, however, in arrangement. Thus, p. 6, last line but five—

Work. $W = FL = (\text{eq. 3}) L^2 M T^{-2}$; we prefer

Work $W = FL = (\text{eq. 3}) L = L^2 M T^{-2}$; or,

Work. $W = FL = L^2 M T^{-2} = (\text{eq. 3}) L$.

Take, again, the tables relating to measures of length, p. 24. The equivalents for 1 and 100 are useful; but equivalents for, say, 1, 2, 3, 4, 5 and 10, would be very much more useful. Further, the money equivalents, p. 32, ought to be extended. Estimates are not made for France only, but for every civilised nation under the sun; but while 90 per cent. of business men know something of French money, a lesser number know about Spanish, Portuguese, Italian, Brazilian, Chinese, Japanese, &c. Jumping to near the end, p. 422, we object to the attempt to Anglicise "galvanoplasty." Such alterations as we have suggested, and similar ones, would further improve a work upon which the authors have evidently spared no pains to

make as comprehensive and useful as possible, and which, in fact, is a necessity to every man connected with electrical engineering.

CORRESPONDENCE.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I hope you will allow me to state a few words in reply to the letter appearing in your last issue signed "F. C. Allsop." What he states about the trials of Mr. Reckenzaun is quite true; but the lines upon which I am working are different. In the article by J. L. Huber it will be seen that practice has dictated the use of a double armature. If Mr. Allsop will think again, he will perceive the reason of both armatures being perfectly cool because the strain is divided. Had the full strain been placed upon one, it would no doubt have become very much heated.

One of the main points I aim at is to keep the armatures as cool as possible, because of the fact that when a conductor becomes heated its resistance increases. Hence the advantage of starting upon each journey with a cold armature.

Another feature, and a very important one too, is the fact that a tramcar in ordinary traffic *must keep its time, no matter the number of stoppages.* Two armatures enable this to be done far better than one at any time a good speed is required with a heavy load. As to cost, the car in question has never exceeded *per farthings per mile run for coke burned under the boiler,* and this consumption will be reduced to a halfpenny as soon as the cars can be got to work. The comparison is considerable between the seven ton electric locomotives at Stratford and their load and the self-contained cars which I propose, which will not weigh a pound over four-and-a-half tons. There will be only sixty cells, weighing, with their total contents, 50lb. per cell.

I am decidedly of opinion that electric traction, like everything else, will stand or fall by its commercial value. If a farthing per mile can be saved over horse haulage, depend upon it it will be only a matter of time to displace the horse for tramcar haulage.

The report referred to does serve a purpose, and that is, the amount of energy used to do a certain amount of work, the present car complete weighing five tons. The repeated trials with accumulator cars in my experience has had a good effect upon the public mind, and tramway companies, like sensible people, will see any system of electric haulage thoroughly proved first upon all points before they will adopt it. One thing is certain, no half hearted men need touch the subject of electric traction, and those that have the pluck and energy to carry it out to a successful issue should have their just reward.—Yours, &c.,

Brixton, S.W., May 30th, 1888.

A. J. JARMAN.

TAVENER COULOMB METER.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR, As you inserted in last week's *Electrical Engineer* a description of an electric meter by Prof. Elihu Thomson, which is identically the same in principle as one patented by me in 1884, and, as a correspondent has called your attention to the matter, I feel I should not leave the indication of my claim entirely to others. I may add to what your correspondent has already stated that had there been no patent to fix the date of my prior claim, I could have brought ample testimony that I had been some time prior to 1884 experimenting on the heating effects of the current, with the object of constructing an electric meter, as it appeared to offer the only means of making a generally useful instrument applicable both to alternating as well as to direct currents, and which resulted in the adaptation of the tube with bulbs to that purpose as the only solution of the difficulties of using the heating effects of the current in the way I have with a variable surrounding atmospheric temperature and pressure.—Yours, &c.,

J. TAVENER.

South View, Basingstoke, Hants, May 29, 1888.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

THOMSON v. THOMPSON.

"Unfortunately I arrived just at the conclusion of Sir William Thomson's address," said Prof. Sylvanus P., "but I have just one question to ask, and that is, When will Sir William supply us with electrical measuring instruments at half-a-crown each, as accurate for their purposes as are the cheap watches for keeping time?" The audience laughed, and many of them ridiculed the idea of Sir William Thomson's splendid instruments being obtainable for half-a-crown. This we may fairly say was not Prof. Sylvanus Thompson's idea. Had he cared to explain—unless indeed our interpretation of his meaning is wrong—he would have said that the world of pure science needs instruments of the greatest precision, and these Sir W. Thomson is supplying; but the world of applied science does not require instruments of such great precision, nor indeed can it use them if it has them; but it requires something cheap, handy, and fairly accurate—instruments that will survive a considerable amount of rough usage. Examples of the use of the two classes of instruments can be selected in any direction. The draper who measures so many yards of calico, troubles himself nothing at all about the accuracy of the standard yard. The ordinary surveyor with his chain troubles himself nothing about the accuracy of a base line for a trigonometrical survey. The object of the standard yard is not to measure calico, nor is the accurate base line wanted to obtain the area of the kitchen garden. The draper's measurement is perfectly satisfactory for all practical purposes, so is that of the ordinary surveyor. Just so, then, may less precise calculations be satisfactory for all practical purposes in electrical engineering work, and the workman will be satisfied to get a correct result within '01 just as much as if it was correct to '00001. Prof. Sylvanus Thompson took an example of cheapness and accuracy of measurement from the work of watch-makers, but he would be the last man to contend that the cheap American, Swiss, or English watches were sufficiently good timekeepers for standards in astronomical work. He would admit both classes of instruments had their uses, and we should be inclined to contend that his question was put to the wrong person. It is not to Sir William Thomson that the scientific world looks to produce instruments that are "about" right; they rather look to him for the accurate scientific weapons by means of which they can tell the "aboutness" of those instruments called for by Prof. Sylvanus Thompson. Messrs. Schuckert, Deprez, Ayrton, and Perry, Kapp and Crompton, Muirhead, Paterson and Cooper, Howard, Appleton, Burbey and Co., and such like designers and manufacturers are the people to whom we must look for these cheaper tools for the workman, and it may fairly be maintained that their part of the work has not been

badly done, or the period which has elapsed since the want was felt been unduly long before the cheapening commenced. It may well be said that the function of the standard yard is to measure other yards, so the function of Sir William Thomson's admirable series of instruments seems to be to measure, compare, or standardise other instruments rather than be placed themselves in the dynamo rooms for everyday use. Generally, and within certain limits, cost is directly proportional to accuracy, and, other things being the same, the cost of the instrument accurate to '1 will be less than the cost of the instrument accurate to '01. Thus, before Prof. S. P. Thompson can safely determine the price at which an instrument should be sold, he and others holding similar views must determine the point of accuracy to which these cheap instruments are expected to work. Something was said about accuracy to one per cent., and so far as the greater part of electrical engineering work is concerned, that percentage of error might not be inconvenient, but there are many cases in which it could not be allowed. Perhaps the accuracy that will be tolerated for practical purposes may be set down as '001, and if what is said about the extreme accuracy to which electrical measurements can be carried, there ought to be little difficulty in getting the cheap working instruments to the accuracy we have mentioned.

CRITICISM ON THE ELECTRIC LIGHTING BILL.

It is a great pity that some of the writers upon this subject do not make themselves acquainted with the rudimentary principles of trade and finance. In the last number of the *Local Government Chronicle* is a short article on the Electric Lighting Bill, in which are the following remarks:—"The experience of the present generation in towns where the gas works or water works are owned by companies ought to be a warning for all time against the setting up of any similar monopolies. If the electric light had been as great a success as gas soon became after its introduction, we doubt whether the terms imposed by the Act of 1882 would have had much effect in deterring enterprise; and until some company can show a large margin of profits from its electric undertaking, we doubt whether the present Bill will have much effect in stimulating it."

The electric light industry has not asked for a monopoly—it does not want it; but it wants fair play and just that latitude and licence that is given to almost every other trade under the sun. Does our sapient contemporary think that a grocer or a tailor would do much in the way of business if he knew that before he had time to look round a second party could step in and say, "I'll take your business off your shoulders at my own price." Does a full-blossomed business drop into the hands of any man who

opens a shop and sets up a sign? How many years elapse before the capital sunk in making a business is returned? The great cry of many engaged in electrical engineering is that they cannot influence sufficient capital for the work in hand or in sight. The capitalists say no business under the sun can succeed if handicapped with such provisions as that under discussion. They will not wait five or six years for a dividend while a company is being developed; they want a good return at once; and till there is some prospect of this and of a continuity of return great difficulty will be experienced in the matter of capital. Talk about monopoly! If there was the slightest chance of monopoly, capital would be plentiful; but confiscation is rather the term to be used, and the word frightens those who hold the purse strings. Generally, the consent of two parties is necessary to make a bargain. You cannot compulsorily purchase the farmer's cow because he has had it six months or six years. In fact, the case of the farmer, which has been so much discussed of late years, is somewhat analogous to that of the electric light company at the end of twenty-one years. He has agitated and has been granted compensation for "unexhausted improvements"; but under the old Bill the company neither got return nor compensation; and though we admit forty-two years is better for the undertakers, the principle is radically wrong. If the concern is to be taken over compulsorily at any time, it should only be by paying a fair and square compensation.

ENGINEERING ELECTRICAL.

Electrical work as heretofore carried out up to the last few years was little else than purely electrical. Now the case is widely different, and will become rapidly more so. An electrician who has not been through the mechanical engineering shops, and who undertakes a large installation comprising machinery and boilers, gearing and shafts, may sometimes involve himself in considerable difficulties through not sufficiently considering, or being able to consider, the engineering part of his plant. In the future, no doubt, electrical engineers will more and more be engineers quite as much as electricians, but at the present time there are a large number of electrical engineers who need further experience in the latter half of their business. It is often useless to expect these to give up a year or two of their time to be re-apprenticed to an engineering firm to obtain a thorough training by going through the shops. There are, however, several ways of meeting the question which it might be quite worth while to point out. Not the least efficacious of these methods, of course, will be to attend a course of mechanical engineering instruction where practical work in engineering is allowable, and where occasion is afforded for fixing, taking to pieces, and repairing steam engines, gas engines, and shafting. But it may be quite worth the while of some of our more advanced electrical engineers to obtain when they can a position in an avowedly engineering firm—many of such we could name who do not lay themselves out to make electrical machinery, but who do make a speciality of engines and machinery connected therewith. A person with good electrical knowledge, and willing to help and learn, might there find both scope for what he does know and ample opportunity for furthering the development of what we have called his "engineering electrical." These firms

constantly work in conjunction with true electrical firms, and the experience thus gained would no doubt serve many who now labour somewhat under a disadvantage when the heavy part of their work has to be considered. As a third resource, we would have them not forget that our friends the mechanical engineers are our friends, and are ever ready and willing to help us in any difficulty with which they themselves are better able to grapple. Especially would that be the case when any pecuniary or contractor's advantage might be looked forward to. The electrical engineer should feel that he has at his back, as permanent consulting engineer, the whole of the best of the mechanical engineering trade, to whom he can go to in confidence in case of difficulty of arrangement in engineering skill—a partner to whom he should not hesitate to look to, who is ever ready to help, and whose help when taken will often obviate many faults, bring into use many labour saving suggestions, and enable the resulting work to redound to the credit of both.

INSTALLATION AT PEARS' BY MESSRS. LAING, WHARTON, AND DOWN.

We herewith illustrate the dynamo and battery rooms of what is perhaps one of the prettiest of the London installa-

tion of the year falls almost wholly upon the storage battery. Current is taken from it not only for the incandescent lamps, but also to actuate a small Immisch 4 h.p. motor, which works the lift. The fittings used are principally simple and neat office fittings, but an exception

Imitation Roman Lamp. Pears' Installation.

must be made to the bronze lamp used in the ante-room, which is fashioned after the manner of the old Roman hand lamps, and looks extremely tasteful. It is perhaps hardly necessary to add that the grouping of the incan-

PLAN OF DYNAMO ROOM.—PEARS' INSTALLATION.

tions. It could hardly be expected that one of the greatest, if not the greatest, advertisers in the whole world would miss the opportunity offered by the electric light, and especially so as it combines profit with pleasure. The profit arises in that, all things considered, at the present moment "it doth give Pears' a cheap advertisement," and the pleasure from the fact that the working staff get a better light and better ventilation than would be the case using any other illuminant. It is beyond our province to enter into any detailed description of the architectural features of the building, but it is worth a special visit to Oxford-street to see the ante-room, and to view the pictures. The electric light plant consists of two of Crossley's "Otto" gas engines, one driving a Thomson-Houston machine for arc lighting, the other a Jones dynamo for charging a storage battery. The arc lamps are not much used in summer time, so that the work at this

descent lamps in the ante-room is specially arranged to effectively light the exquisite marble statuary.

PATERSON AND COOPER'S MEASURING INSTRUMENTS.

In an ordinary small engineering job, if there is no special need of scientific testing, measuring instruments, in the ordinary sense, are not required. There are the pressure and water gauges for the boiler, but with dynamometers and work and speed counters for the machinery we can usually dispense. With electrical engineering this is far from being the case, the agency being invisible, and no installation is nowadays complete without its ammeter, voltmeter, and speed-counter. Without measuring instruments the elec-

trical engineer works in the dark. If anything goes wrong he is at sea, but with proper instruments he can soon trace the fault. The electrical profession, as a whole, is not a little indebted to Messrs. Paterson and Cooper, who have taken up in a business spirit the clever inventions of Profs. Ayrton and Perry, Captain Cardew, and others. The new illustrated catalogue of these instruments has reached us, and we take the opportunity of drawing attention to the various points. The well-known Ayrton and Perry ammeters and voltmeters come first, with all recent improvements—simple form, calibrated in amperes and volts direct; or commutator form, with commutator in parallel, reading either direct or ten times the amount. Directions and formulae are given for recalibrating. Electro-magnet ammeters, in which the values of the deflections are constant, measuring from 25 to 2,000 amperes,

16 and an arc lamp of 2,000 c.p. Speed counters, galvanometers, and resistance boxes complete the pamphlet.

WOODHOUSE AND RAWSON'S SWITCH-BOARD.

This switch board is intended to be used on an installation where the dynamo current is used to charge accumulators, besides being used for ordinary lighting purposes, &c. The centre switch is used when charging the accumulators, also when using them on line. It is arranged with a resistance coil on the two contact arms so as to prevent short-circuiting the cells when moving from one contact to

Gravity-Controlled Engine-room Ammeter.

Combined Portable Ammeter and Voltmeter.

and rougher engine room ammeters are also shown; and a combined portable ammeter and voltmeter, with leather shoulder strap for use in testing installations. An extremely neat little voltmeter is illustrated with a dial and case about the size of a Waterbury

the next, and also to prevent sparking. The moving arm is laminated, so that each section has an independent bearing upon the contact blocks, thereby ensuring full area of contact. The two side switches are of the G type, and are for the dynamo circuits.

Simple Ammeter with Permanent Magnet.

Pocket Voltmeter.

Electro-Magnet Dead-beat Ammeter.

watch, measuring from 1 to 10, or to 80 volts. It weighs 6oz., has a permanent magnet, and needle working in jewelled holes. The Cardew voltmeter has been slightly improved in small details, and by passing a current for many days through the wires before calibrating, it is ensured that they are perfectly stretched before sending out. In the Cardew voltmeter the indication is caused by the proportionate heating and lengthening of a fine wire; it has, therefore, no need of coils or magnets, and it is equally applicable to alternating as to direct current systems. It does not require recalibration, and it is the only one that has the advantage, sometimes considerable, of being able to be kept continuously in circuit without injury. Prof. Thompson and Mr. Starling's universal photometer is illustrated in its arrangement for measuring both an incandescent lamp of

At the top are two magnetic cut-outs, which are arranged so as to automatically break the circuit should the current exceed the required amount. These with a slight modification can be made to break the circuit when the E.M.F. rises too high. The instrument at top in the centre is a resistance switch, which can be used for throwing resistance into the field magnets of the dynamo. On the shelf at bottom is a voltmeter of standard type (see catalogue for description), with switch, so that the E.M.F. on line and at terminals of dynamos may be tested with it, also two ammeters of standard type, one for dynamo and lamp circuit, and one for accumulator circuit, so that the accumulators can be charging at the same time that the lamps are lighted.

The whole of the instruments are mounted on a slate slab, with name plates, &c. The permanent connections

being made at the back, with copper strip, each instrument having copper connectors passing through the slate, and screwed and soldered to the copper strip, so that the switch-board, with the instruments upon it, can be fastened to the wall, and the cables connected to external terminals. The slate has a strong wooden frame at the back to keep it from the wall, and, if desired, the whole is enclosed in a strong mahogany case with glass doors, lock and key, &c.

PORTABLE ELECTRIC LIGHT PLANT.

The accompanying illustration represents a portable electric light plant made by Messrs. Paterson and Cooper for Mr. A. B. Simpson, of Bombay. The boiler, engine and dynamo are mounted on a strong cast iron bedplate, provided with wheels, so that as a generating plant the whole is self-contained. The "Phoenix" dynamo is compound-wound for a difference of potential of 60 volts, and therefore suitable for burning incandescent lamps in parallel with arc lamps, or either separately. The boiler is 6 h.p.

Portable Electric Light Plant.

nominal, and steams at 80lb per square inch. The engine is a 6in. by 6in. "Invincible," by Gwynne, of Hammer-smith, and the dynamo, which is coupled direct to its crankshaft, gives, at a speed of 350 revolutions per minute, 60 amperes at 60 volts.

INSTALLATION BREAKDOWNS.*

BY REGINALD J. JONES, A.S.T.E.

It has been aptly said we learn more from our failures than our successes. In no branch of science does this apply more truly than to that of electrical engineering. A breakdown is, perhaps, the best practical test of the efficiency of the *main* part of an installation.

Speaking very generally of breakdowns, they may be divided into four great classes:

1. The motive-power.
2. The electrical generating and storing plant.
3. The conductors.
4. The lamps and fittings connected therewith.

With regard to the first, it is outside the object of my paper to go into details of accidents in connection with steam or gas engines, turbines, &c., but in passing it may be stated practice seems to point out that the best results as far as continuity of supply of current, for whatever pur-

pose it may be required, is obtained by using several engines and dynamos instead of one large one, for with the latter condition it is simply a question of time before you have a breakdown. From an economic point of view it would seem, too, that the former is the best arrangement, as friction is proportionate to the load.

The following points are essential in connection with the management of long running engines, shafting, &c.:

1. Examine every bolt and nut, such as on eccentric straps, &c., before starting. Do not trust to luck.
2. Tap all cast-iron fly-wheels, riggers, &c., to see if they are cracked.
3. If there are joints in bands or splices, examine carefully before starting.
4. Have electrical heat alarms on the main bearings.
5. Clean and tighten all electric connections.
6. Provide a water supply over the main journals in case of need.

Prof. Thompson, in his admirable paper on "Diseases of Dynamos," pointed out the most probable sources of failure in these machines. From actual experience, it will now be

W. House and Rawson's Switchboard.

my endeavour to tell you a few acute cases, with their symptoms, causes, and cures.

ARC DYNAMOS.

Firstly, we will consider some cases of arc light dynamos failing to work, owing to faults (first) in the armatures, (secondly) the fields, (thirdly) the connections, and (fourthly) the driving gear.

The machine we will consider first is a 16 light arc Brush machine. A short time after starting sparks were noticed on the outside of the armature coils when they passed the pole piece, where the coil is cut out. These in a very few minutes became so big that the dynamo had to be stopped. On examination, the insulation between some of the wires on a coil was found to have been scraped away, and a small arc was formed. The spark only occurred when the coil was cut out of circuit, the extra current causing it then to jump the air-space. The cure was effected by blocking the wires apart and putting some tape, soaked in shellac varnish, to insulate them.

Another breakdown of a brush armature may be here mentioned. A 16 light dynamo, on being started with the circuit open, instead of showing very small sparks, kept up a continual flashing round the commutator. The cause of this was the breaking down of insulation between the wires of the armature coils in the bundle, and thereby causing a circuit through some of these armature coils—this generally necessitates a new set of wires connecting the coil and commutator.

* Paper read before the Old Students' Association, at the Finsbury Technical College, on May 29.

Connections.—In some large engineering works, a Brush dynamo had been running the lamps on the previous night well; but towards the end of the run some smoke was seen to come from under the wooden base, on which the copper springs, which connect the brushes to the outside circuit terminals and fields, are mounted. As is very often the case with non-electrical persons, the water cure was tried, but naturally without success, and on the following night the machine would give no current at all. By short-circuiting from the brush to the terminal, so as to cut out the connection below, the dynamo started all right; the cause of the trouble was the nut clamping the brush spring to the wire connection below becoming loose and starting an arc. The arc carried the current all right as long as the machine was working; but on cooling down these metals were further apart, and coated with a poor conducting film having too high a resistance for the machine to build up current through it. A cure was effected by taking off the washer, scraping the dirty surfaces, and securing it in place again.

Another mishap coming under the head of connections occurred to a Brush dynamo running in a central station. The only symptoms were a sudden flashing over on the commutator, then total extinction of the lights. On stopping the dynamo it was tested with a detector to see if the circuits were intact. No deflection could be got by testing through the terminals of dynamo, but keeping the galvanometer and battery still on, and examining the wires which connect the fields, the needle was found to move when one wire was handled. Ultimately it was discovered that the tin sleeve joining the two wires had been placed considerably more on one than on the other. The solder which had hitherto held the wires in place was melted. Further tests showed a short circuit on the mains; thus, the lead acted as a fuse, and probably saved something more expensive to repair.

Driving. One rather curious accident happened to an arc light dynamo, which was driven from a countershaft with a very tight short-drive belt. About half an hour after starting the night's work the machine flashed continuously at the commutator, the engine raced, and finally the belt was thrown off the machine. This was replaced, and a second time there was a repetition of the flashing and racing of the engine. On putting treacle on the belt and tightening up slides these troubles disappeared.

The cause was this. A sewn joint had been made in belt in the morning, and a new piece of leather introduced. This suddenly stretching, caused engine to race, dynamo to flash, thereby increasing racing of engine, finally causing belt to slip off dynamo pulley.

Driving Gear.—A fault in the driving gear of an alternating current machine assumed an uncanny bearing by appearing just at nine o'clock every night. The machine was driven by a gas engine and a leather link belt. To all appearances everything was in its normal condition, the lamps were up to full E.M.F., &c., but just at nine o'clock the belt began to run to one side of the pulley, and always ended by coming right off. This occurred for many nights in succession. At last we found, by putting some waste on belt as soon as the symptoms of running off occurred, the belt would run all right. At last it was found that the main bearing oil way was stopped, and all the belt surface became coated with oil about two hours after starting, thus causing the belt to lose its grip.

In the maintenance of high tension arc dynamos, the following are important points to be observed:

1. Have the framework of the dynamo thoroughly insulated from earth.
2. Keep your commutator segments and brushes scrupulously clean.
3. Keep the commutators thoroughly wiped during running. Never use articles like sponge cloths to wipe commutator of open segment type. A case once came under my notice where this was done—the public did not think much of the experiment from a lighting point of view, and there were four brushes to straighten.
4. Keep the oil from getting in among the wires leading to commutators.
5. An automatic regulator on the fields reduces the risk of breakdown very much.

ARC LIGHT BREAKDOWNS.

By no means the most secure portion of a high tension system of lighting is that comprised under the heading of circuit. These may be divided into two distinct classes or types—viz., overhead and underground. In the former the chief risks are from breakage, due to stress of weather or flaw in materials used, accidental contacts of other wires, such as telephone, either causing a short circuit or damaging the instrument, and, lastly, liability to atmospheric electrical discharges. In big cities the continuity of supply is frequently endangered by fires breaking out. The advantages may be said to be cheapness of erection, ease of testing, and maintenance.

In the underground system the great danger is the difficulty of maintaining insulation and cost of putting down the system. The advantages of underground systems are the freedom from breakdown in heavy weather and stability, and certainly it must strike every mechanical engineer as being a better job. We will consider first a few cases of overhead breakdowns.

In an arc light circuit in some large engineering works, when the circuit was tested for insulation on a certain day, by bridge measurement it varied from 400,000 ohms to dead earth. The insulation would then remain high for half an hour at a time, and again vary intermittently from zero to the maximum. This went on for several days, until it occurred to me to test on a Sunday, when the works were stopped. On this occasion there was a permanent dead earth. After a little cutting of sections the weak spot was traced out, when it was found that a portion of cable had been dragged away from the cleats by a travelling crane, and was rubbing against a fast and loose pulley, the insulation being rubbed right through. When the cable rested on the belt there was good insulation, but when the belt was shifted to the other pulley it rested on the iron and gave dead earth.

In one case of arc lighting from a central station, run on the overhead system, the following occurred. On the previous day, the conductor was about 15 ohms, including lamps. The lamps ran perfectly well until midnight, the usual stopping time. On testing the conductor next day it was found to be 3,000 ohms. The fault could not be discovered by lighting up time, so we decided at any rate to try what would happen by starting the dynamo, everything lit up as if 3,000 ohms, more or less, were a mere matter of detail. Afterwards, we found it really lay in a quadrant switch, which had become loose, the two contact surfaces were covered with little incrustations caused by the arcing. On the machine building up this spurious resistance disappeared.

In another long circuit of arc lamps, the circuit on being tested showed a perfect break of continuity, while at the same time the positive end of the cable gave good insulation and the negative a dead earth. There had been a heavy gale during the night, causing a lamp to become unhooked at one terminal only, consequently the chimney touched the iron hood, which was in contact with earth, while the unconnected terminal gave perfect insulation—hence the necessity of snap hooks.

A very curious phenomenon showed itself in connection with a series system of transformers on an alternating high tension system. There was a leakage to earth on the mains somewhere. On placing an incandescent lamp in series to earth in the engine room, the filament was incandescent. As many as 18 lamps could be put in series, all lighting up with a very small difference in illuminating power to the single lamp. It would be of interest to know if others have observed a similar thing.

In dry climates, such as South Africa, they have to put comb collectors over the brushes of the dynamo, to discharge the atmospheric electricity from the line. In England, too, we occasionally suffer.

During a heavy thunderstorm a breakdown occurred on an arc light system of underground wires. A portion of the lamps on circuit were suddenly put out. The lightning had struck a lamp post, burnt out coils and lamp cut-out, then broke down the insulation of cable at two places, so that a portion was short circuited, thus cutting out a loop of the cable, with the lamps included in it. Still following up this subject of underground arc

circuits, the following is interesting in showing how the faults were eliminated. The symptoms were: The engine raced and dynamo flashed. On going round circuit a portion of the lamps were found to be out, and it was seen that No. 1 fault lay on the wire before No. 1 lamp. The dynamo was stopped, and circuit broken at No. 1. The dynamo was again started, so that current ran through faults only. We then followed line up by opening street boxes and tested for current with a compass needle, and found fault lay between two boxes. Dynamo was again stopped, and a temporary cable connected through over-ground.

ARC LAMPS.

The arc lamps themselves are frequent causes of trouble in the circuit. The Americans call this the specific cussedness of the lamps; the minor faults are so numerous that they would fill a paper by themselves.

The following, however, is a somewhat curious example of some of the freaks of arc lamps. A set of 40 arc in a public building had been running very well for three or four months, when suddenly, night after night, lamps in various parts of the circuit would burn very dull red, get duller, and finally go right out. The dynamos were in good order, the current the same, and the insulation perfect of machines and circuits, yet sometimes as many as eight or ten lamps would be out together.

To discover the cause, a lamp was taken down low, and someone put on to watch its behaviour. Then was noticed a sort of bubble of molten liquid collecting on the positive carbon, which trickled down into the arc. The lamp then gave only red glow, the globule gradually cooled and finally short-circuited the carbons. The difficulty was thus solved, for it was then remembered that a fresh batch of carbons had been used since the commencement of the fault. On changing these for good carbons we had no further trouble.

Let us now consider a few points in connection with low-tension systems.

INCANDESCENT DYNAMOS.

Driving Gear.—A very puzzling, though simple, fault occurred in a compound dynamo, which had been running extremely well for several months, until one night when it was found that, with the full complement of lamps, only 20 volts could be obtained instead of 80. On running the machine light, the full E.M.F. was shown on the voltmeter. The circuits of the dynamo and those of the installation were tested and found to be in perfect order—the engine and dynamo were running at normal speed. Eventually, on going to take the speed at the commutator end, it was observed that the end of dynamo shaft and commutator were rotating at different speeds. On further investigation it was found that the commutator and armature, which were mounted on a sleeve, were slipping round the shaft, the set screws having slackened away. The load, of course, dragged the armature back, whereas when light it rotated at proper speed.

Connections. A mistake in coupling up led to a curious result with another compound dynamo: the direction of rotation was changed, and the shunt wires only were crossed. On running the machine light, with the pilot lamp only, the dynamo worked all right; but on putting the whole load on, as the series coil now worked against the shunt, the light may be best described as a minus quantity. We have yet another instance of faulty connections in the case of a new shunt dynamo installed, but all efforts failed to get it to build up. The insulation of the armature and fields was perfect, the field circuit was intact, and to all appearances the armature wires were not broken. There was no sign of sparking at the brushes at any angle, or any speed. The cause of this was that the field connections had been by mistake crossed and connected to the wrong terminals, probably after varnishing. Reversing these caused the dynamo to magnetise without further trouble.

ARMATURES.

We find that the armature is the part of a dynamo most liable to disaster. In series wound or compound dynamos there is great danger of an excess of current causing fusion or breakage should a short circuit occur. Another fault common to armatures is shown in

the following breakdown. A small shunt dynamo, which was used for charging accumulators and driven by a gas engine, exhibited these symptoms: no current could be got through the cells, but the machine would run a few lamps direct. There was, however, continuous sparking at the commutator. On taking adrift a pair of wires on the commutator a break was found (by testing with a galvanometer) in one of the coil wires just where joined to the commutator. One circuit of the armature was always supplying current, and whenever the broken part passed the brushes, sparking occurred. On repairing this breakage the machine worked well again. The following, too, is an interesting case of the mischief damp causes. Two 300-light plain shunt dynamos were used to run an installation. They were run generally week and week about. After a week's idleness one dynamo refused to build up at all. On testing with a battery and detector the armature was found to be in connection with the shaft, and on further inspection was discovered to be quite damp. Then it was remembered that a pane of glass in the skylight above had been cracked during the week, and through it rain had dripped on to the machine. To restore the insulation a small current was kept on through the armature, the heat set up dried out the moisture, and the machine worked perfectly again.

Fields. Apropos of the extremely bad habit of breaking the circuit of a dynamo by lifting the brushes whilst the machine is running, the following case shows the effect on the constitution of a machine. A four pole shunt machine had been doing its work perfectly well for some time, until one night it was found impossible to get the full amount of light. The machine was taken to pieces, and a hole was found on one field burnt right through insulation consisting of three layers of calico steeped in paraffin, and the layer of paper and two holes were found on the other pole, thus short-circuiting a pair of limbs of the magnets. The attendant here had been in the habit of breaking the circuit with the machine running at a high speed.

Armature.—A very serious structural weakness of drum armatures is exemplified in the following case, which occurred to a compound machine running incandescent lamps. By some external means the mains were accidentally short circuited; the main fuse went, but did not go before allowing a considerable rush of current through the armature. This caused the end band binding (made up of fine steel wire) of the armature to burst before the dynamo could be stopped; quite a number of sparks were seen at the pole-pieces, accompanied by a very strong smell of shellac burning. The pilot-lamp over the dynamo, however, burnt properly. On examination of the armature, it was found that the sparks were caused by loose steel wire ends striking against the pole pieces; and the smell of shellac was probably due to heating of the wire by friction, and consequent heating of shellac on armature wires—the latter were quite uninjured.

In connection with the subject of bands breaking, a very novel accident occurred to a generator supplying current for a tramcar. The dynamo was a 300 volt shunt machine. The plant had been working well for some hours. On the first part of the journey the tram had to go up a stiff incline, while just before the terminus the incline was in its favour; the current at this point was switched off. The car completed one journey, but on trying to start again the machine would not build up; the circuits and insulation were tested with a galvanometer, and found in perfect order. The fields were then externally magnetised by a hand dynamo, all other means having failed. For a while the dynamo worked all right, but again broke down, exhibiting the same symptoms, except that now the field was broken. After the second stoppage it was found one of the armature-bands had broken, and the broken ends, in rotating, had cut through a field magnet circuit. This, however, had fused together again, probably by the arc caused by extra current; but how the permanent magnetism of the poles disappeared was never made very clear.

These bands very frequently break. It would be interesting to hear from others what has generally been the cause of this—viz., bad mechanical fastening of ends, insufficient initial strength, fusion through contact with opposite sides of armature, or some such cause as the above first case.

COMMUTATORS.

The next part of the dynamo we will consider as a cause of breakdown is the commutator. As would naturally be supposed, the copper dust cut by the brushes and oil used in wiping the surface of commutator frequently gave trouble. As examples of this fault, two cases may be cited—the first of a compound machine which, after running well for some time, began to spark very much, the armature becoming unduly heated. The cause was found to be copper dust and grease getting in behind the leather shield which covers right close up to the commutator, and causing a partial short circuit.

The second case was that of a series-plater, the commutator segments of which have air insulation below and between them. Here, after a while, a little mound of copper dust accumulated under the segments, eventually short-circuiting the commutator on to the steel shaft. To effect a cure the segments were removed and cleared. A second weak point is in the ring which clips the segments together at the end. Cases have come under my notice in which the insulation has broken down, and a short circuit established.

As Professor Perry in his recent lectures has shown us, the mechanical engineer seems sometimes to think that a dynamo being a new departure, old methods may be neglected and has strangely forgotten or left out precautions which he would in all other high-speed machinery adopt. The following case, bearing upon this point, came under my own notice. The makers of a well known ring armature made their machine so that at the pulley end the inside face of the pulley was made to act as the distance-piece to prevent side play of the armature. The pulley itself was fixed on by a feather and secured at the end by lock nuts; these while running worked loose. The result was a general firework display and a job for the armature winders, for although an armature puts up with very little clearance at the pole-pieces nowadays, it draws the line at actual contact with the same.

We now pass on to consider incandescent lamps, circuits, fuses, &c

INCANDESCENT LAMPS.

Unlike arc lamps, the faults of incandescent lamps are not as varied. The principal causes of failure may be stated to be weakness of the glass bulb, which frequently breaks under atmospheric pressure; weakness of a portion of the globe at one point, as specimen exhibited; leakage at the points where platinum wires enter, and bad vacuum resulting therefrom; want of symmetry in diameter of filament, hence heating unduly at one point, causing rupture ultimately; want of stability of filament, causing it to fall to one side touching the glass and breaking it; deposition of carbon on the glass, &c. In very bad lamps the sudden expansion of gases has caused the globe to burst outwardly. The glass at point where the platinum enters sometimes cracks, due to imperfect contact and arcing.

Fuses.—No one will dispute the fact that the circuits of an incandescent system may be a source of danger to a building if not properly installed. As it is now a *sine qua non* that all such work be protected from short circuit or leakage with fuses that danger is reduced to a minimum. It would seem to me that the system most likely to give best results in placing of fuses is one which reduces the number of these to as few as possible consistent with safety. By this is meant that there should be a double pole fuse placed at the root of a branch so that the fuse will go should a current pass, by leakage or short circuit, which would dangerously heat the smallest wire on that branch. In the future it seems likely that double-pole magnetic cut-outs will be more extensively used for this purpose, as this form may be relied upon to go at a given current.

As an instance of the result of improper use of fuses, there is the not uncommon fault of putting in single-pole fuses indiscriminately. This has doubtless been the cause of some trouble, and one case came under my notice where a sub-circuit was burnt right out through this. From a well-authenticated source, the following very curious case, where combination of gas and electricity were responsible for some damage, has been given me. An ordinary lead wire fuse gave out through excess of current passing, and

actually set fire to some gas which was escaping from a pipe close by. One great source of danger in an installation otherwise admirably protected by double-pole fuses arises from the fact that in these double-pole fuses both terminals of the mains are brought close together and bared. It would be far better, in my opinion, if two separate single-pole cut-outs were inserted, one on each main.

Alternating currents seem to cause molecular movement in wires. A case which came under my notice in a building, in the basement of which was a three-light electrolier, the lamps of which all began to flicker very rapidly; the cause was at last traced to the fuse, which was found to be working loose. From my experience of alternating currents, it seems that nuts always tend to work loose. Hence another reason for reducing the number of points of fuses.

It would be of great interest to hear if others have noticed the same phenomena more markedly in alternating circuits than in those of direct currents. As may be generally known, the fuses for the high tension currents used for transformers are made of copper wire passed through sheets of asbestos, which are inserted to break the arc when the fuse goes. This asbestos seems to have a peculiar corrosive action on the copper wire, for at the points of contact the wire gets green, and soon eats away. *Appropos* of fuses and incandescent circuits, it would be of great value to all to hear of some authenticated cases of a fire arising from a minute leakage, but one not great enough to cause the fuse to go.

Insulation. In concluding this interesting part of the subject, the following example of breakdown of insulation may serve as a warning to those who take what is sent them without making any tests. A whole floor of a large hotel had been very carefully wired, as far as mains were concerned, with a new cable laid in a wooden casing let in the joists, and on the wiremen completing the work the cable was tested to see if there was any sign of leakage. A very sensitive astatic galvanometer was used with a 200-volt chloride of silver battery. To their dismay, the cable showed a leakage of about 80 degrees—they were absolutely sure it was kept perfectly free from iron or earth contact. To find the fault the whole of the covering was taken up, and the mode of laying examined. Nothing could be seen, until at last it occurred to me to cut off a short length and test it. This was done by getting a fairly damp brick and laying the cable on top, putting one wire to the core and one to the brick.

The leakage deflection was reproduced, and on carefully overhauling the cable a small portion was found touching the brick work of one of the walls. It was then ascertained that a new outside compound had been tried on this cable in manufacture, which caused the insulation to be a partial conductor, and thus rendered it unfit for active service.

Automatic Leakage Detector.—It is often the case to find the insulation of an installation, which was at first many thousand ohms, fall rapidly from some cause or other after short use. I should like to make the suggestion here that a very useful piece of apparatus might be invented, and if made sufficiently cheap would no doubt be specified in all large installations to indicate at once when the insulation resistance of the mains fell below a certain point. This might be left permanently on the circuit on both mains, with an arrangement to call attention if the resistance fell below a predetermined point.

CONCLUSION.

It has been very difficult to make anything like a connected story of these chapters of disasters from the nature of the subject of the paper. I trust, however, that benefit may be derived from the simple enumeration of these defects and their causes. There are several instances of breakdown here quoted of Brush machines. The Brush dynamo I consider the best in the market, and that the instances, many of them from this class of dynamo, is simply from the fact that I have had more experience with this any other class.

In conclusion, I must thank several of my friends who have been kind enough to assist me with tit bits from their own experience.

COMPARATIVE VALUE OF THE ALTERNATING TRANSFORMER AND CONTINUOUS CURRENT SYSTEMS FOR CENTRAL STATION LIGHTING.*

BY F. B. RADT.

We have heard three papers on apparently the same subject, though each of these papers was named differently by its author. I know a good many of you are under the impression that I will be an advocate of the alternating system against the continuous current system; but such is not the case. In the title I have given my paper I have narrowed this discussion to its proper limits. I do not believe, by any means, that the alternating transformer system will be substituted for isolated lighting, or for lighting within moderate distances, but I do believe that, for an economical central station lighting system, the alternating transformer system is the best in existence. This remark may seem superfluous; but lighting within short distances, and even isolated lighting, has been dragged into the discussion on this subject. Although the author of the first paper read apparently tried to show that the only practical system for central station lighting of to-day is the three-wire system of, say, not exceeding 230 volts, I propose to show to you that this attempt is not even consistent with the practice of the company this gentleman represents. In the first place, let me read an abstract of a circular concerning the Edison municipal system.

I quote: "The Edison municipal system has especially been devised to meet all the requirements of perfect outdoor illumination. . . . The current used in this system is of high tension (1,200 volts), which would be unsafe to introduce into dwellings, hotels, stores, or buildings of any character, where the wires and sockets are liable to be handled by inexperienced persons, but when they are stretched on poles in the open air, and the lamps are attended by persons who have been properly trained, all danger to the public ceases. If desired, the circuits for this system can be laid underground at a reasonable cost.

"Each lamp is screwed into a socket, which is protected from rain by a metal hood, and in the upper part of the hood is placed an apparatus that closes the circuit whenever a lamp carbon breaks, thus keeping the continuity of circuit uninterrupted. At the same time an instrument in the station indicates the breakage, so that the attendant may be sent out with another lamp to replace the broken one. N.B. I hope he is provided with a bicycle.

Secondly, I will quote from a paper read by a gentleman during the Edison convention in Chicago, February, 1888: "A modification of the Edison three-wire system was mentioned where two Edison 600 volt, 26 ampere dynamos furnished current for several hundred lights, five 100 volt lamps being used in series on either side. The dynamos run without sparking. There is no more evidence of high pressure visible at this plant, or in the municipal 1,200 volt machine, than with 125 volt dynamos. There is probably no more perfect plant running than this, which has been in service since the middle of last year." And again, "Within proper limits, the principle of high pressure is not absurd or inconsistent with correct principles of future progress. The idea underlying the transformer is the logical outcome of experience, but thus far we have no satisfactory application to general commercial uses excepting possibly through the electric motor.

Now, in both cases, an electromotive force of 1,200 volts is employed, and they call the last-named system a "modification of the Edison three wire system." If what we heard in the first paper is true, why does the same company employ an electromotive force up to 1,200 volts? The 1,200 volt three wire system, as I understand it, is used for store lighting, and is introduced into houses, while in the pamphlet concerning the municipal system the introduction of 1,200 volts into houses is condemned.

Where is logic! Where is consistency! I cannot see it, but I hope that during the discussion, which probably will follow the reading of this paper, some of the gentlemen will be kind enough to explain it to me. I am well satisfied that there is a tendency, even among the most

ardent advocates and admirers of the low tension system for central station plants, to occasionally raise the electromotive force when they cannot raise the necessary money to buy copper enough for their feeders and mains on the 230-volt three-wire plan. There is certainly less objection to even a 1,000-volt alternating transformer system than to the introduction of a 1,200-volt continuous current into houses.

Now, what I believe is, that all these systems, namely, multiple arc, three-wire, and multiple series continuous current, as well as multiple arc, multiple series, and transformer alternating system—are good in themselves, and that it is our task to find the proper places and the proper conditions for each. Each one has its place. We all agree that for isolated lighting, the multiple arc system is the best; whether continuous or alternating is a question which I do not want to answer here. For longer distances we will properly use, according to circumstances, multiple series of two lamps (three-wire) or multiple series of more lamps, again either continuous or alternating. And for still longer distances, we will employ a general system of incandescent lighting, where all points near and far must be reached in order to supply all customers the alternating transformer system. These few remarks will probably outline my ideas of the application of the different systems of incandescent lighting under different conditions. What I want to show, however, to-night is the comparative value of the alternating transformer system and the continuous three wire system for central station lighting. I will adhere to the points named in the previous papers, namely: 1st, first cost; 2nd, economy, efficiency, and depreciation; 3rd, reliability; 4th, variety and value of the possible sources of revenue; 5th, safety to life; 6th, effects upon existing property.

First and Secondly. First Cost and Economy, Efficiency and Depreciation.

It was shown in the first paper that the cost of the conductors transmitting a given amount of energy at given loss for a given distance varies inversely as the square of the initial E.M.F. employed. Figs. 1 to 6 show the combined cross section of copper feeders at five per cent. loss for 500 16-c.p. 110 volt lamps at a distance of one mile. They represent:—

[It is not necessary to show these sections. We give the diameter in inches. Ed. E. E.]

Fig. 1, multiple arc. (110 volts, 3½ in. diameter)

Fig. 2, three wire system, according to Prof. Forbes (220 volts, 3 in. diameter).

Fig. 3, three-wire system, according to H. Ward Leonard (220 volts, 2 in. diameter).

Fig. 4, five 110 volt lamps in series (550 volts, ¾ in. diameter).

Fig. 5, alternating transformer system (1,000 volts, ¾ in. diameter).

Fig. 6, alternating transformer system (2,000 volts, ½ in. diameter). The ratio is as follows:—

TABLE NO. I.

Fig.	1	2	3	4	5	6
System.	Multiple Arc.	3-wire Forbes.	3-wire H. W. Leonard.	Multiple Series.	Alternating Transformer.	
E.M.F.	110	220	220	550	1,000	2,000
Ratio of cost of feeders	320	216	108	13	4	1
Cost of feeders per lamp at 5 per cent. loss at one mile.	\$71.00	\$53.00	\$23.00	\$2.80	\$0.85	\$0.21

I think this table is perfectly clear without any further explanations. I will repeat, however, the statement made by Mr. Slattery, that according to Prof. Forbes (*author Lect.*), the saving of the three wire over the multiple arc system is only 25 per cent., and that to assume any more saving may suit American financiers, but is not electrical engineering. The originator of the so-called Edison three wire system (Dr. Hopkinson, of England) thoroughly concurred with Prof. Forbes in this view.

For the sake of argument, however, I will assume, whenever I speak of the three wire system, the figures given by Mr. Leonard, or a saving of 66½ per cent. over the multiple arc system.

* Read before the Chicago Electric Clubs, April 23, 1888.

Table No. 1 also shows the cost of feeders per lamp, at 5 per cent. loss, at one mile, assuming the cost of copper at 20 cents per pound. In Mr. Leonard's paper the parallel was drawn only between the 1,000 volt alternating system, employing 50-volt lamps, and the three-wire system, employing 110 volt lamps. I hardly think this fair, as it increases the cost of copper wires for the secondary circuits four times the cost of the copper wires in the branches of the three wire system. In making this comparison the most economical alternating systems employed to day in Europe and America should be considered. These systems employ an E.M.F. in their primary mains of about 2,000 volts, and use 110 volt lamps in their secondary circuits. Any improvement which in future should be made in these lamps will, of course, be an improvement in the alternating transformer system as well as in the three wire system.

Now, in comparing the cost of the two systems, I will, for the sake of argument, again compare the three-wire system to the 1,000 volt alternating system. Let us assume that the cost of feeders per lamp at a certain distance for a 1,000 volt alternating system at $2\frac{1}{2}$ per cent. the loss is one dollar. Then, according to Mr. Leonard, the cost of the copper for the three wire system would be 27.50dols. Table No. 2 gives the cost of the two systems at $2\frac{1}{2}$ per cent., at 5 per cent., at 10 per cent., and at 20 per cent. loss.

TABLE II. Comparative Cost of Feeders per Lamp.

Loss in Feeders.	3 wire Syst. m.	1 000 volts Alternating System.	Difference of Cost between the two Systems.
$2\frac{1}{2}$	\$27.50	\$1.00	\$26.50
5	13.75	.50	13.25
10	6.87	.25	6.62
20	3.43	.12 $\frac{1}{2}$	3.30

You can very easily see that the ratio in columns 2 and 3 is the same; but I want to draw your attention to column 4, showing the difference of cost per lamp in the two different systems under the conditions named. Suppose, now, that the cost of machinery, including boilers, pumps, engines, dynamos, house wiring, and lamps in each case is about 15,000dols. for a 1,000 light plant. We would have to add in the three wire system, figuring on 20 per cent. loss with full load.

$$1,000 \times \$3.43 = \$3,430.$$

In the alternating system we would have to add $1,000 \times \$1.25 = \$1,250$.

But we will allow five times this amount in order to enable us to get a wire of very high insulation. This would make 625dols. In addition we should calculate 3,000dols. for transformers (3dols. per lamp). This would make a total of 3,625dols.

It must be borne in mind, however, that a pole line, or underground conductors for the three-wire system, would be much more expensive than for the alternating system for obvious reasons.

This would give us the following total result. — Total cost of 1,000 light three wire system, 18,430dols. Total cost of 1,000 light transformer system, 18,625dols.

This would show the three wire plant 195dols. cheaper than the alternating plant. But now let us make some calculations on $2\frac{1}{2}$ per cent. loss in the feeders, and we find that the feeders for the three wire system would cost $1,000 \times \$27.50 = \$27,500$, and for the transformer plant 5,000dols. (again allowing five times the cost of copper for good insulation) and 3,000dols. for transformers, making total cost of 1,000 light three wire system, 42,500dols. Total cost of 1,000 light transformer system, 23,000dols. This would make the transformer system 19,500dols. cheaper than the three-wire system.

You can very easily see the trick in this calculation. Take a certain amount of money as cost for the entire plant, excluding copper feeders in both systems, and also excluding transformers in the alternating system, and assume a comparatively high loss in feeders, the difference in cost for such feeders in the two systems will then appear as a small percentage of the total cost of the plant. Then assume a high efficiency of such conductors, say only $2\frac{1}{2}$ per cent. loss, and the cost of such

feeders will be a very large percentage of the total cost of the plant. You see in column 4 of table No. 2, that, though the ratio at different losses is the same, the difference in cost will appear very small when a large loss in the feeders is allowed.

This method of calculation is not electrical engineering, but is, instead, a calculation invented and probably patented by some selling agent who worked on commission. You can very easily see that if you want to sell a low voltage system, a high loss must be assumed, but if you want to sell a high tension transformer system, a small loss in feeders is permissible and competitive with the low voltage copper mine system. Thus, you can make the total cost of the low voltage plant appear smaller or greater than the total cost of the alternating plant, as occasion may require. I very reluctantly make public this trick of the trade, but there is no charge for it to those gentlemen who should not have known it.

Now the question, of course, could be raised, why not figure on a higher percentage of loss in the feeders and still get the good results as shown in the first paper? I simply say this. Assuming a high loss in copper feeders is poor electrical engineering, it is a permanent waste of power; it requires complicated apparatus and permanent attention to keep the pressure alike in the different feeders with varying loads; it will cause greater lamp breakage, as necessarily, even in the best laid out system, the potential will very often rise in some of the branches far above the normal; it necessarily must be quite a complicated task of electrical engineering to get all the conditions right for best results. On the other hand, with a small loss and a nearly constant pressure kept at the main distributing points, all these difficulties disappear. The electrical engineering part becomes very simple, and lamps can be attached almost anywhere to the line without throwing the system out of balance. Simply the impossibility of advocates of the low tension three wire system inducing capitalists to spend money enough for such large conductors, as a small loss in the feeders would require, prohibits them from acknowledging all these advantages; and they necessarily must claim that it is good economy to lose more energy in the wires.

You can very easily see that the average load and loss question in table No. 1 of the first paper was simply introduced in order to make the loss appear smaller than it really is. Now, I think I can save a good many arguments by simply referring you to the picture which you behold here. It represents a low tension three wire system in Minnesota. The first pole near the station carries all the outgoing wires. There are fifty four, varying in size from No. 0000 wire to No. 6. About one half of the wires are No. 0000, and the remainder in varying sizes from 0 to 6. Don't forget to scrutinize this corner pole. Lamps of various c.p. are put up, whose equivalent amounts to about 7,500 10-c.p. lamps. The average number of lamps burning during the day amounts to 2,000, while the average number in use during lighting hours is about 7,200. The loss in these feeders amounts, with full load, to about 20 per cent. In one circuit it is even more. The claims, as far as economy is concerned, are ten 10-c.p. lamps per h.p., including the loss in the conductors. The station is equipped with 10 dynamos, five engines and boilers for about 1,000 h.p. There are 14 employes connected with the station. The coal consumption for 24 hours is about 53,000lb.

Now taking these data, and the picture before you, do you think that the theoretical tables and curves we had explained in the first paper were known to the gentleman who laid out this station? The fact of the matter is that such a station as is illustrated can neither be economical nor on a paying basis. It can be only the laughing-stock of electrical engineers except those who own some stock in the concern.

A 2,000-volt alternating system would, of course, show up far better than a 1,000 volt system, as far as first cost and economy is concerned. Even granting that the efficiency of an alternating dynamo is not quite as good as that of the continuous current dynamo, and that a small percentage of loss will occur in the transformers, what are these in comparison with the enormous loss in the

feeders of a three wire system, and the necessity of all the complicating balancing devices at the station necessary in that system?

There is one point, however, which has not been touched upon, and that is that the whole calculation made in the first paper was based upon the fact that the number of lamps fed by different feeders was at all times reduced in the same proportion. I know, from practical experience, that in most plants this is hardly ever the case, and that resistance must be introduced to equalise the varying losses in the different feeders. This not only means waste of power continuously, but it also means wages of employees to watch the necessary instruments continuously, and to keep the different feeders balanced. So much for economy and efficiency. Of course, I do not want to repeat all the points covered in the paper read by Mr. Slattery, nor by the latest communications to the electrical journals made by advocates of the alternating system against the three wire system as expounded by Mr. Leonard.

As far as depreciation is concerned, let me again draw your attention to the beautiful picture of the Minnesota three-wire station made by our special artist, and let me simply ask the question, Would you rather repair transformers, or would you prefer to keep a pole line covered with a net work of naked wires in repair? Suppose customers did not renew their contracts for lighting, which would be cheaper, to take a transformer and place it somewhere else, or have a high priced electrical engineer sit down and calculate how to balance that line again, and take a couple of hundred lights from one place and transfer them to another point on the circuit? These points, I think, naturally apply to the chapter headed "Depreciation."

I grant that well insulated wire will depreciate more rapidly than bare copper wire, but for my part I would prefer to keep six well insulated wires in repair than a pole line with 54 naked wires as here illustrated.

Whether the depreciation of a high tension dynamo is greater than that of a low tension dynamo is a question that can only be answered after more experience than we have had up to this time.

Thirdly, Reliability. I can see scarcely anything in the corresponding chapter of the first paper which still needs answering. I certainly cannot see, that for the reasons given, a continuous current system is any more reliable than a transformer system. Again, let me draw your attention to the picture. I think that in the network of wires represented troubles are more likely to occur than in six well insulated wires. Practical experience so far has not shown that the alternating transformer system is not as reliable in operation as the low tension continuous current system.

That a switch-board in an alternating central station plant should be more expensive than a switch board and the necessary apparatus to run a three wire plant is something very surprising to me. I think that from what I have seen of the two systems, that the trips used in a three wire station plant cost at least five times as much as those used in an alternating plant. What our contemporaries in Europe think of the reliability of the two systems will best be illustrated by the following examples.

First—Milan, Italy, had a low-tension direct current 10,000 light station. To reach a theatre 6,500 feet off, they added a Zipernowski-Deri 1,800 volt alternating transformer system, using underground cables.

Second—Dijon, France. This town had a low-tension direct current central station, located in the centre of the town. The City Council regarded the noise of steam engines, smoke, &c., in the heart of the city a public nuisance, and compelled the local company to go to the outskirts. The company abandoned the whole continuous system, and replaced it by a Zipernowski-Deri 1,800-volt alternating transformer system.

Third—Rome, Italy. A large central station is being erected, and is partly finished—all done on the Zipernowski-Deri 1,800-volt alternating transformer plan, with a capacity of about 18,000 lights at distances of 10,000ft. to 16,000ft.

Where is the low-tension plant reaching customers at such distances? I could go on in this way *ad infinitum*, but I think these few examples will suffice.

Fourthly, Variety and Value of the Possible Sources of Revenue.—The question of increasing the income from the

central station by renting out power has been ventilated before, and it has been shown that it is not by any means impossible to run motors on the alternating transformer system. It has been found, furthermore, that in practice it is advisable to run a separate circuit for the distribution of power. There is no objection to using continuous current dynamos for this purpose. It could be said that extra dynamo capacity would be necessary in such cases, but I hardly think this is true. It certainly cannot be expected that the same dynamo will run day and night in succession without ever stopping. I think that a certain reserve is necessary in any event. In the central stations I have seen only a part of the dynamo capacity is used during the day, and the whole during the main lighting hours in the evening, leaving no reserve whatever. If these same dynamos should be loaded, running motors all day, there would be in my opinion a continuous strain put on the apparatus, which is certainly not advisable.

I quote from the first paper the following: "Then there is an almost unlimited number of applications of a continuous current on a small scale for such purposes as fire alarms, burglar alarms, distribution of time, annunciators, tickers, electro plating, telegraph lines, and telephones, all of which rely upon a continuous current."

Now, I would like to have somebody tell me from what central stations such applications have been made on a large scale and on a paying basis. I do not know of any, and I think no central station would like to be troubled with these little nuisances. The amount of money which could be gotten as revenue for furnishing current to these appliances would certainly not compensate for the trouble they would continually cause. Therefore I must say that I cannot see that the alternating system is any more dependent for its revenue upon the sale of light alone than a continuous current system.

Fifthly, Safety to Life. The danger to human life from high tension alternating currents is always held up as a bugbear by the advocates of the low tension continuous system. In the first paper it was stated that it has been conclusively proven in practice that a 1,000 volt alternating current is fatal to human life and will kill a horse. I do not know of any experiments made in that direction, but it would certainly be interesting to know how much larger an animal than a horse could be killed by a 2,000-volt alternating current. A telephone operator at Pittsburg, who was killed dead by the first paper with a high-tension current, while handling the switch board at the telephone exchange, has come to life again in a communication to the *Western Electrician*. Maybe the same will happen yet with the horse. The fact of the matter is that at least ninety cases out of a hundred where persons have been killed by the high-tension current, death has been caused by the extra current set up in the field of a series dynamo when the external circuit was broken by the victim. Now, gentlemen, this danger does not exist in any alternating system.

The field of the alternating dynamo is separately excited, and such a powerful extra current cannot be set up and discharged through the body of the careless workman even in case he should break the external circuit. I therefore claim that the main cause for fatal accident does not exist in the alternating high-tension system. There is another danger which I think is greater in the continuous current system than in the alternating high-tension system. Just look at that picture hanging before you, again, and imagine a workman in that network of wires short-circuiting two of those heavy copper conductors by some means. The result would be a pound or so of molten and fused metal, which would not only inflict very severe wounds, but might even prove fatal. Quite a number of cases have come to my knowledge where persons have lost their eyesight or got otherwise mutilated by such accidents. You must remember that the wires of a low tension system are mostly bare, while the wires of the high tension alternating system are well insulated. It may be asked why, in the case mentioned, the safety strips would not prevent such an accident. I will say, that heavy fusible plugs melt rather slowly, and would not break the circuit in time to prevent the accident. The

smaller safety strips of the high-tension alternating system, carrying only a few amperes, would respond a good deal quicker, though, as mentioned before, such an accident is less liable to happen in this system.

Sixthly, Effect upon Existing Property. Why a low-tension continuous system should be better protected by safety strips than a high-tension alternating system is a conundrum to me, and I refer to the discussion of this matter following the reading of Mr. Warner's paper. The inductive influence which might cause trouble to telegraph and telephone lines can be just as easily avoided in a transformer as in a low-tension direct current system. For underground work I think a cable would prevent all such troubles, and would furthermore prevent the retardation of the alternating system as explained in a brief article of mine published in September last. It may be mentioned here that wires carrying an alternating current are not in danger from electrolysis, and that the wires keep cleaner if fastened underneath ceilings or on walls. Wires carrying continuous currents will very soon show a layer of dust and dirt, which will appear as a demonstration of the magnetic whirls surrounding the wires.

In conclusion, I will give a *resumé* of the advantages of the alternating transformer system, as used for station lighting, in comparison with the three-wire system of distribution.

Advantages.—1. Location of central station plant need not be in the expensive centre of the city, but cheap real estate and power miles off can be utilised, thus decreasing the cost materially.

2. All customers near and far may be reached on a paying basis.

3. The price of conductors for feeders and mains is reduced to a minimum.

4. These wires being very small, the cost for poles and erecting lines, or of underground work, is materially reduced.

5. It does not take any great electrical engineering skill, or complicated calculations, to lay out such a system and make any alterations which may be necessary in the course of time.

6. The system is very simple, requires comparatively few stationary appliances, and fewer employees for regular running and repairs.

7. The small loss in the feeders will result in greater efficiency, more lamps to the horse power, smaller engines will be employed, less fuel consumed, and the earning capacity of the whole plant will be greatly increased.

8. It is easier to keep the electrical pressure constant, thus burning the lamps at all times at even c.p., and lengthening their average life. *Western Electrician.*

PROVISIONAL PATENTS, 1888.

MARCH 27.

4673A. **Improvements relating to incandescent electric lamps.** Philip Middleton Justice, 55 and 56, Chancery-lane, Middlesex. (Charles H. Fisher, United States.) (Complete specification.) Note. The application having been originally included in No. 4,673, dated 27th March, 1888, taken under Patents Rule 23, that date.

MAY 18.

7399. **Optical telegraphy or spectro-telegraphy.** Henry Harrington Leigh, 22, Southampton-buildings, Chancery-lane, Middlesex. (Paul La Cour, Denmark.)

MAY 19.

7463. **Improved alternating commutator.** Maximilian Kotyra, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex. (Complete specification.)

7479. **Improvements in insulation in electrical machinery and apparatus.** Frederick Lawrence Rawson and William White, 1, Queen Victoria street, London, E.C.

7480. **Improvements in insulation in electrical wire or in its supports or carriers.** Frederick Lawrence Rawson and Wm. White, 1, Queen Victoria street, London, E.C.

MAY 22.

7487. **Improvements in electric switches.** Gustav Binswanger, 5, Great St. Thomas Apostle, and Herbert John Coates, 6, Lawrenson-row, Bow, both in London.

7510. **Improved portable easy-chargable safety fluid battery.** Ernest Gütthardt Kemps, 22, Hamilton street, Camden Town, N.W.

7522. **Dynamo-apparatus.** Edward John Houghton, 1, Putington-road, Peckham, S.E.

7523. **Means and apparatus for electric lighting.** Edward John Houghton, 1, Putington-road, Peckham, S.E.

7530. **A portable electric safety lamp.** Ernest R. Chittenden and Ernest Edward Vaughton, Le Lion Kingston-on-Thames, Surrey.

7536. **Improvements in galvanic batteries.** Benjamin Wilcox, 47, Lincoln's inn-fields, London. Thomas Palmer Whittier (United States.) (Complete specification.)

7541. **Improvements in electric machines.** William Phillips Thompson, 6, Lombard street, Liverpool. Henry W. Spang (United States.) (Complete specification.)

7543. **A floating telegraphic or telephonic station or apparatus for enabling ships at sea to communicate with one another or with the shore.** Urban Dieuleveult, 47, Lincoln's inn-fields, London, W.C.

7551. **Improvements in and relating to coupling devices for electrical and other purposes.** John Kendall and Owen Cooper, 45, Southam-buildings, London, W.C.

MAY 23.

7585. **The combination of telephones with multiple signalling circuits.** Alfred Whaley, 2, Whitehead's-grove, Chelsea, S.W.

MAY 24.

7619. **A primary electric battery.** George James Weir, 22, Renfrew street, Glasgow.

7636. **Improvements in holders for electric incandescent lamps and shades.** Joseph Appleton, William Thomas Burley, and Albert Edward Williamson, Balmain Buildings, 91, Queen Victoria street, London, E.C.

COMPLETE SPECIFICATIONS ACCEPTED.

APRIL 18 1887.

5648. **Improvements in apparatus for making and breaking electric circuits.** John Henry Holmes, 46, Lincoln's inn-fields, London, W.C.

JUNE 24, 1887.

9017. **An improved method of heating ores and other substances by an electric current for effecting metallurgical, chemical, and other operations, and furnaces or apparatus therefor.** William Cross, 46, Lincoln's inn-fields, London.

JULY 22, 1887.

10,240. **Improvements in field magnets.** Luther Hanson, Commercial street, Halifax.

APRIL 11, 1888.

5362. **Improvements in arc lamps.** John Henry Holmes, Portland-road, Newcastle-on-Tyne.

5713. **Improvements in electric elevators.** John Keese Hallock and George Canfield Buckensleifer, 77, Chancery-lane, London, W.C.

APRIL 20, 1888.

5913. **Improvements in electric telegraph, telephone, and electric-light insulators.** Arthur West Heavyside, 7, Grafton-road, Whitey, Newcastle-on-Tyne.

SPECIFICATIONS PUBLISHED.

1887.

1333. **Oxydising and decomposing by electrical action organic matter, &c.** W. Webster. 8d.

COMPANIES' MEETINGS.

ORIENTAL TELEPHONE COMPANY.

The adjourned eighth annual general meeting of the Oriental Telephone Company, Limited, was held on Friday last at the City Terminus Hotel.

Mr. B. St. John Aekers presided, and in moving the adoption of the report stated that in preparing the accounts for the annual meeting on the 25th ult. they decided that until the Indian guarantees expired it would be better to keep the balance-sheet in the same form as before. Just prior to the annual meeting, however, the Board received an opinion of counsel respecting the legality of the payment of dividends by the former Directors, and thus unexpectedly, the question arose as to whether the dividend now recommended of 2 1/2 percent, on the paid-up capital other than the vendors' shares could be paid. There was no other course but to adjourn the last meeting, but the Directors had since taken the opinion of their legal adviser, as well as that of the Company's auditor, and also that of an eminent accountant unconnected with the Company, and they had been confirmed in their opinion that the assets were fully equal to the liabilities, and that the proposed dividend might be paid. His proposition at the last meeting had thus been verified, but it had been necessary to recast the balance-sheet the revenue and profit and loss accounts, however, remaining unaltered. The patents and goodwill account had been written down by £42,930, and that item now stood at £71,000. Lower down on the asset side of the balance-sheet it would be observed that the deferred shares had been brought up and valued altogether, and the various sums had been carried out into one total. Now that the guarantees had expired, there would be no deferred shares in connection with the Indian companies, and the items of shares and debentures in subsidiary companies had been written up from £45,760 to £89,115. The total of

the balance-sheet now came to £209,432, against £209,067 as shown in the balance-sheet submitted to the 31st December last—in other words, after the assets had been carefully valued and rearranged, it was seen that they were amply sufficient to meet all liabilities, with a small profit over of £365, thus increasing the item, on the other side of the balance-sheet, of sundry credit balances to £2,239. He therefore thought the shareholders would consider that the Directors were justified in recommending the proposed dividend, and he believed that the distribution next year would be sensibly increased. At the same time, it would be very unwise to divide everything, for they had no reserve fund, and they had no way at present of obtaining any extra working capital except by making a call on the shares. The vendors' shares amounted to £75,000, and were at present nominally £1 paid, while the other shares of £1 each had 11s paid. He trusted it would be possible by some means to make an arrangement by which the vendors' shares should be reduced in amount, the liability on the other shares extinguished, and the vendors' shares rank very soon for dividend. If such an arrangement could be arrived at the shareholders would be greatly benefited, and he was sure that that would be greatly for the benefit of the Company. He was glad to state that an agreement had been come to by which the Company's rights over the whole of Australia, New Zealand, and Tasmania were recognised and by which they would also receive an annual amount in royalties. The one reason why they had not obtained all that they ought to have obtained was that the Melbourne exchange had been purchased by the Colonial Government.

The Right Hon. O. Cavendish Bentinck, M.P., seconded the motion, which was unanimously adopted, and resolutions were afterwards passed declaring the dividend mentioned, and re-electing the retiring Directors and Auditors.

NOTES.

City of Mexico. The plant here is being greatly enlarged, and it will soon be one of the best-lighted towns in America.

Paris.—The Prefect of Police having forbidden the use of gas at the Conservatoire at Paris, this hall will be lighted by electric light.

Senegal. Saint Louis, in Senegal, is having the electric light. Senegal will be the first of the French colonies to be publicly lighted by electricity.

Long Life.—The American journals mention an Edison 16-c.p. incandescent lamp, first fitted on January 17, 1884, which has lasted 18,000 hours' actual lighting.

Prof. Bell in England. Prof. Graham Bell was to have sailed for England on June 2nd, to attend before the Royal Commission on the instruction of deaf mutes.

Book Received.—"The Management of Accumulators and Private Electric Light Installations," by Sir David Salomons, Bart., M.A. Fourth edition, revised and enlarged. (Whittaker and Co.)

Sprague Motor Car. Ten summer open cars have been started on the Richmond, U.S., electric road, 40 now men having to be engaged. Everything ran smoothly and without hitch, and 13,000 passengers were carried.

Strand. At the last meeting of the Strand District Board of Works, Messrs. Dyson wrote, with copy of a letter from Messrs. Bircham, stating that this district had been struck out of the South Metropolitan Electric Lighting Provisional Order.

Electric Light in Every Cell.—The buildings of the Industrial Reformatory, Huntingdon, Pennsylvania, are fitted with modern improvements in the shape of steam heating and electric light. The 500 cells each contain an incandescent lamp.

Maxim-Weston. It is announced that the "Watt" dynamo of the Maxim Weston Electric Company, Limited, has now been officially added to the Government list as eligible for the lighting of Her Majesty's war ships, as well as for shore installations.

Electric Light on a Sandbar. At Newport Harbour, U.S., the authorities have for some time felt the need of a better light, and arrangements are made with the torpedo station near to supply electricity for a powerful arc light to replace the present oil lamp.

The Bank of England.—The Bank of England have now had the 500 light installation at work some time, and are so far satisfied with the result that they have instructed Messrs. Drake and Gorham to proceed with the electric lighting of their new branch at the Law Courts.

Long Distance Telephony. Experiments in long distance telephony (between Dijon and Marseilles, 500 miles) last week have been attended with very satisfactory results. Those between Marseilles and Noyes, a distance of 600 miles, are not so satisfactory, and are being continued.

Magnetic Iron Separator.—We are informed that this machine, about which we enquired last week, was exhibited at the Inventions Exhibition by Messrs. Ernest Scott and Co., the Close Works, Newcastle-on-Tyne, who have since sold some of the machines to the Government for the Arsenal at Woolwich.

Catalogue Received.—Messrs. Appleton, Burbey, and Williamson have sent us their catalogue, with illustrations of simple, neat, and cheap types of switches on china bases, and earthenware and slate fuses, and also china and ebony lamp holders. Their address is Balmoral Buildings, 91, Queen Victoria-street, E.C.

A Pension to Reiss. We are glad to learn that the claims of inventors who have not worked their inventions to commercial success are sometimes recognised. Just before his death the late Emperor of Germany awarded to the widow of Philip Reiss a pension of 1,000 marks annually, in recognition of the services of her husband.

Southend Pier. The engineers of the new pier, Messrs. Brunlees and McKerrow, 5, Victoria-street, Westminster, propose to use electricity as the motive power for the tramway on the pier; the power to be generated by a dynamo driven by a gas-engine, placed in the arch beneath the approach. Question has also been raised as to electric lighting for the town.

Edinburgh.—The Streets and Buildings Committee of the Town Council, at a meeting held last week, has approved of the sub-committee's report, under which permission was given to the Anglo American Brush Electric Company to lay down wires in Rose-street for the lighting of the Princes-street hotels and shops with electric light under certain conditions.

Cautious. The Ministerial Council of Alexandria have just approved of the project for lighting the city by means of electricity, but only on condition that the contractor will hold himself responsible for all damages that the Egyptian Government might be called upon to pay to the gas company, should the latter deem it advisable to take legal proceedings against them.

Tenders for Bath. According to advertisement appearing elsewhere in our columns, the Corporation of Bath ask for tenders for public lighting for a specified area with arc lights, either overhead or underground system, to be maintained by contractors at their own cost for a period of three, five, or seven years. Tenders to be sent to the Guildhall, Bath, by July 2nd.

Secondary Batteries.—A secondary battery has been patented by Mr. Ludwig Epstein, of Martinikenfelde, near Berlin, Germany. This invention covers a method of preparing powdered lead for electrodes, consisting in adding sulphate of lead to molten metallic lead, and stirring the liquid mass until it has been transformed into a finely-divided powder, with other novel features.

Belfast. The Belfast Harbour Commissioners are considering the question of lighting the harbour, rendered necessary by the construction of a straight channel, and intend examining into the method of gas buoys adopted at the Clyde. Why should they not use the incandescent electric lamps for this purpose—a method very satisfactorily adopted by the United States Marine authorities?

Gas Companies and Electric Light.—At Toledo, Ohio, the Gas Light and Coke Company have taken the bull by the horns in the enterprising manner recommended by us to English gas companies some weeks ago, and have fitted up electric light machinery sufficient to light the entire city. The installation is said to be a model of its kind; power is supplied at present by two 150 h.p. engines, and the steam is obtained by the surplus heat from the gas works.

Electric Torpedo.—A submarine torpedo has been constructed for the Spanish Government by Major Cabanyes, an officer in the Spanish Army, in which the motive power is furnished by an electric motor of 60 h.p., Brown-Erlikon system, driven by a battery of 60 accumulators of a new type, about which absolute secrecy is kept. These accumulators have an extremely large capacity, and have been tested for some months by the Spanish Government with most satisfactory results.

Single Line Electric Railway.—The first public trial of the Eads system of single rail elevated electric railway took place at St. Paul, Minnesota, lately, according to local reports, with satisfactory results. The track has an average of $6\frac{1}{2}$ per cent. grade, with many turns of short radius. The car, loaded with spectators, made many trips under complete control of a single operator. A speed of six miles an hour was maintained up the steep grade, and the system was pronounced a perfect success.

High-Pressure Boilers.—For some time past there has been a tendency amongst electric light engineers in America towards the use of higher steam pressures, as they find it advantageous in many ways, with their high-speed engines, particularly in the matter of economy of fuel. The Brush Electric Light Company, of Buffalo, are using boilers designed to carry a working pressure of 200 lb. per square inch. Boilers have been supplied in some cases for a working pressure of 235 lb., and are working perfectly satisfactorily in every respect.

Underground Wires in Philadelphia.—The Town Council have control of all electric wires, and some time ago they determined all overhead wires should be put underground, and this has now been completed. The Brush Company of that city have one wire five miles long working at a pressure of 2,800 volts; it has an insulation of three-thirty seconds of an inch thick, covered with lead one-eighth thick. The Keystone Company have also a fifteen-mile circuit working at 2,000 volts, and no difficulty has been found in working it.

Electric Welding. The right of working the German patents of MM. Bernados and St. Olszewski, of St. Petersburg, is said to have been acquired by the Dresden Bank; while Rothschilds, of Paris, are reported to have acquired the exclusive rights for France, Belgium, Spain, Italy, and Austria. The invention relates to the direct application of an electric current for working metals, and more especially of forming alloys by the same method. The preliminary trials at St. Petersburg and at Creil, near Paris, are said to have been very successful.

Belgium. The Belgian Academy of Sciences has given the following questions for consideration at its meeting in 1889:—(1) Set forth and complete the state of our knowledge on the variation, in different solvents, of the electric conductivity of salts in different degrees of concentration; (2) Set forth and perfect the methods which are used to determine the elements of the terrestrial magnetism. Two gold medals, of the value of 800f. and 600f., are offered for the best solution of these questions, which must be sent in by the 1st of August, 1889.

Bohemia.—The town of Neuhaus, in Bohemia, has a central electric station established by Count Czernin, who is land owner of the district. The municipality have signed a contract for twenty years for lighting the streets with 85 incandescent lamps. The current is supplied by two

dynamoes driven by water turbines, and the wiring, on the three wire system, is carried on poles along the streets. Private installations to the extent of 365 lamps are now in use, and the demand is extending. A battery of 1,000 accumulators is shortly to be put down to act in case of accident, and to ensure regularity of supply.

Bright Lights.—The electric lights on the Brooklyn Bridge are so bright that the pilots complain they cannot see, and ask for the old lights. Shades and reflectors will probably be put to diffuse the light. A curious accident from a similar cause occurred in Albany. A young law student and a lady friend were out boating one evening, and, when stepping out at the landing, the lady mistook the brilliantly reflected shadow of the landing for the actual landing itself, and stepped into deep water. She was rescued by her companion after considerable difficulty, and now appreciates the fable of the dog and the shadow.

Machine Trench Digger.—A Minneapolis man, says the *American Engineer*, has invented a machine for digging trenches and sewers and gas or electric mains. The apparatus is 50 feet long, but can be made longer. On the front of the machine a four h.p. engine runs two knives, which do the digging. In the rear another engine, which furnishes the power for the apparatus, carries the dirt to that part of the machine, and drops it into the portion of the trench in which the pipe meanwhile has been laid. The trench may be of any reasonable width. Six men attend the monster. It has been claimed that 1,200 yards of pipe can be laid in a day by this machine.

Electric Coal Mining Machine.—A new coal mining company, known as the Electric Motor Company, which has a patent for mining by electricity, will establish a plant at Phillipsburg, Pa., for the mining of an area of 10 miles. The plant, as a whole, is to consist of a central dynamo, conducting wires, coal-cutting machine, electric lamps, and motor attachments for hanging the mine cars. The inventors claim, as an advantage in favour of their coal cutters, that a single machine will not weigh more than 500 pounds. According to estimates, which, it is claimed, are made upon actual tests, the new device will considerably reduce the expenses of mining.

A Slap-dash Rule for Wiring.—Mr. H. C. Spaulding, Boston, writes to the *New York Electrical World* with reference to the recent rules for wiring: "I should like to present for the consideration of the motor fraternity, the following 'slap-dash' rule for wiring. For a 400-volt circuit $H \times D = Cm.$, or number of h.p. to be transmitted, multiplied by the distance in feet, equals area of wire in circular mils. For 600 volts divide by 2. For 220, multiply by $\frac{1}{2}$, and for 110 by $\frac{1}{4}$. I will not say anything concerning the derivation of above; but, if any of your readers have objection to it, or can offer a more convenient and reliable rule, I should be glad to hear from them."

Gas Lighting by Electricity.—A very singular accident happened in Hamburg some weeks ago, according to the *Journal für Gasbeleuchtung*, which took a good deal of inquiry to find the cause of it. In an empty back room, behind a moulding, there were a number of electric light wires. A $\frac{1}{2}$ in. gas pipe was thrust through among these, and one of the electric wires was thereby broken. Its end lay on the gas pipe, and melted a hole in the smith-iron pipe. As it happened, the gas was turned on, escaping while the electric current was off; then came the current and caused the explosion. The gas pipe bears distinct

marks of having been fused at the point where it was perforated.

Electric Lighting in Dublin.—The Corporation of the City of Dublin have applied, under the Electric Lighting Act, 1882, to the Board of Trade for authority to supply the city with electric light. The Lord Mayor, in his speech at the High Sheriff's dinner, asked the High Sheriff whether the condition of the public lighting of the city of Dublin was in a condition in which it ought to remain. He thought that neither in regard to cost, nor the character, nor the control, is the system of public lighting in Dublin satisfactory. Thus appealed to, the High Sheriff stated that, though a director of the gas company, he believed that the supply of light might be improved, and should be under municipal control.

Electric Exchange.—The New England Electric Exchange for granting licenses to electric workmen, about which we had a note lately, has met with considerable support from the insurance offices. We mentioned that the Fire Underwriters had announced their willingness to co-operate with the electrical contractors in the matter, but it appears they have thought well to go much farther than this. In the announcement just issued, the Exchange states that "after October 1, 1888, the Fire Underwriters will not insure any property where electric light or electric power is used, nor pass any new installation, unless the party operating the plant or making the installation has obtained from this Exchange a certificate of license."

Concession for Electric Lighting. The municipality of a foreign city has asked Messrs. Osborn and Co., 6, Booth street, Piccadilly, Manchester, to propose a scheme for lighting the town by districts, and to find a firm willing to take up a concession for a number of years to be agreed upon. The concession will be for—1. The supply and installation of plant and material for lighting the public buildings, streets, squares, &c. 2. The maintenance of the lighting for a term and for a price to be agreed upon. 3. The right to supply all the plant for the extension of the installation either for public or for private purposes. The installation to be redeemable over, say, 10 years, as may be afterwards arranged. Plans may be seen at above address.

House of Commons.—In committee upon the Electric Lighting Act (1882) Amendment Bill, Sir G. Campbell moved to add to clause 1 the following provision:—"When a local authority duly applies for a license for an area within its jurisdiction, such license shall be granted by the Board of Trade unless the Board of Trade are of opinion that special reasons exist why such license should not be granted, and in such case they shall make a special report stating the grounds of their refusal. The grant of a license to any company or person shall not in any way hinder or restrict the granting of a license to the local authority or to any other company or person, with the consent of the local authority, within the same area." Sir M. Hicks-Beach said the Government could not accept the amendment.

Office Lighting.—After two years' experience, the Prudential Assurance are still further extending their electric lighting plant, under the direction of Messrs. Drake and Gorham, who undertook the first design of the installation. There are at present two engines, each capable of giving over 100 h.p., and a similar engine is now being put down alongside the other two in the space previously occupied by the battery. The new battery is to consist of 264 cells made to Messrs. Drake and Gorham's specification,

and patents by Messrs. Elwell-Parker, Limited, of Wolverhampton. In the first instance the installation was to consist of 1,000 lights as a maximum, so that there can be little question as to the rapid progress which has been made in the business of the Prudential Assurance Company.

Underground Cables in Lübeck.—The mains for the installation at Lübeck, for 20,000 incandescent lamps, are to be laid in a different manner than that heretofore employed in Germany, which has generally been cables heavily sheathed with steel wire. Those employed at Lübeck are to be lead covered, served with an outer covering of hemp, and laid in flat channels of rolled iron, with an iron lid. These channels are perforated at the bottom, so that any water may find its way out. By this means the mains can be laid close under the paving stones. Small junction boxes are used, with short sockets, into which the channels fit, and at the bottom of these sockets are ebonite plates, to which connections are arranged for fusible plugs. Separate testing wires are brought back from each feeding centre to the station.

Electric Bait.—The most *blat* fish that ever wore scales and shunned a baited hook will draw near in thrilled wonderment to an electric light submerged in his native element, and so be allured to his fate. The United States steamer "Albatross" has been fitted with electric fishing lights for the conduct of scientific research, and preliminary experiments with these lights have revealed the fact that the curiosity of fish to investigate this unwonted radiance brings them to the light in shoals. The halt and the maimed of the *pisces* family turn out to see this wonder, and to capture them and all the rest is an easy task. A pocket battery and a scoop net may become, says the New York *Electrical Review*, the successor of the can of angle-worms, the rod, and the minnow-bucket, but we fear the fisherman's enjoyment will be lessened.

Obituary.—Mr. Burchell, of the Sanctuary, Westminster, died suddenly on Sunday last. In the early part of the century he took an active part in the promotion of legislation relating to the great railway systems of the kingdom, and the settlement of many important questions in relation to the law of joint-stock enterprise. More than fifty years ago he was engaged with the late Mr. W. A. Wilkinson, for some time member for Lambeth, in the promotion of the Croydon Railway, one of the first lines connected with the metropolis, and now forming a portion of the Brighton and South Coast Railway system. About thirty years ago, with the assistance of Mr. Charles Pearson, at that time City Solicitor, he succeeded in bringing about the commencement of the Metropolitan Railway. He was associated with the late Mr. J. L. Rickardo in the promotion of the Electric Telegraph Company. The interment took place yesterday at Highgate Cemetery.

Derby Exhibition.—One of the principal features of the Industrial Exhibition, which has been held in Derby during the past fortnight, was the electric light exhibit of Messrs. John Davis and Son, of that town. The dynamo, which was a four-unit "Castle" machine, was driven by a three h.p. "Stockport" engine, and the lamps exhibited comprised a 2,000 c.p. and a 400 c.p. "Castle" arc lamp, with a 400 c.p. "Sunbeam" incandescent, as well as a few Edison-Swan 16 c.p. incandescents. The local gas company was ahead, and with commendable prudence had offered reduced terms to the exhibition on condition that no electric light should be allowed in the main hall, so that the lighting had to be confined to the entrance; but the arc lamp

in the archway leading to the hall was quite near enough to make the gas-lamps within look as sick as if they had lately returned from a rough trial trip on an oil steamer.

Large Motors.—The sizes and powers of electric motors are gradually becoming larger; we shall soon, we suppose, have motors driven by electricity capable of comparison with our locomotive or stationary engines of several hundreds of horse-power. The (Erlikon Foundry, of Germany, are turning out some large-size motors, one of which, a 60 h.p. motor, as reported from Spain, is used for furnishing the power for a submarine boat. At Ansonia, Connecticut, a freight (or, as we call it, goods) train is now working by means of electric motors, to connect the various large mills with the wharf. These are specially-built waggons, and are furnished with a 75 h.p. motor on a special motor car. The motors are of the Van Depoele system, and the road-bed being well and solidly constructed, the running is very steady and smooth, and has given every satisfaction, and the motor car pulls with ease all the cars they have at service. A single overhead conductor is used. The generating power consists of a 125 h.p. Corliss engine and a 100 h.p. Van Depoele generator and exciter.

Low-Tension System.—An interesting little central station installation is at work, says the *Bulletin de l'Electricité*, at Mende, in France. The installation was carried out by M. Lamy, who has established several other central stations in different county towns in France—Chateaulin and others. A continuous current is used at a pressure of 100 volts to supply Khotinsky incandescent lamps to a maximum distance of 850 metres (900 yards). The streets, boulevards, town hall, &c., are all lighted, and the hotels will shortly receive the supply. Engine-power is furnished for the evening lighting—that is, from dusk to midnight—by two 120 h.p. compound engines, driving direct at 120 revolutions, a Thury dynamo giving 800 amperes. The steam is supplied by Babcock and Wilcox multitubular boilers. These are stopped at midnight, and the night service is continued by accumulators charged during the day by a Gramme dynamo, this is driven by a separate 10 h.p. high-speed steam engine, and gives 40 amperes and 150 volts. This arrangement makes a very neat small central installation, and one that may be very usefully and profitably imitated in other small towns.

Electric Actinometer. MM. Gouy and H. Rigollot, in *Comptes rendus*, give a description of a simple and easily made form of apparatus for measuring the intensity of light. They have found that a plate of oxidised copper submerged in a solution of chlorine, bromine, or iodine becomes extremely sensitive to luminous rays, even of the feeblest intensity, and can be employed as an actinometer. In a solution of sea water, two plates of copper, one of them being oxidised, have in total darkness an E.M.F. of some thousandths of a volt. When light is admitted, this E.M.F. increases, the oxidised plate becoming more positive. Two similar plates will equally answer, if only one is exposed to the light. Singularly, the variation of E.M.F. is more pronounced through a circuit of several hundred ohms. The experiment succeeds very well with a Deprez-IVarsonval galvanometer; with a Thomson galvanometer the sensibility is greater still, the effect of a single candle at several yards distance being quite noticeable. The oxidised plate can be easily prepared by heating in a Bunsen flame. This apparatus is very easily made and employed, and may render many services in scientific experiments and other applications.

The Institution of Civil Engineers.—The Council of this Society has made the following awards to the authors of some of the papers read and discussed at the ordinary meetings during the past session, or printed in the minutes of proceedings without being discussed, as well as for papers read at the supplemental meetings of students: For papers read and discussed at the ordinary meetings: A Telford medal and a Telford premium to Robert Abbott Hadfield, A.M.I.C.E., for "Manganese in its Application to Metallurgy," and "Some Newly Discovered Properties of Iron and Manganese"; a Watt medal and a Telford premium to Peter William Willans, M.I.C.E., for "Economy-Trials of a Non-Condensing Steam-Engine, Simple, Compound, and Triple"; a Telford medal and a Telford premium to Edward Hopkinson, M.A., D.Sc., A.M.I.C.E., for "Electrical Tramways: The Bessbrook and Newry Tramway"; a Watt medal and a Telford premium to Edward Rayzand Ellington, M.I.C.E., for "The Distribution of Hydraulic Power in London"; and for a paper printed in the proceedings without being discussed, a Watt medal and a Telford premium to Prof. Victor Auguste Ernest Dwellshauvers Dery, for "A New Method of Investigation Applied to the Action of Steam-Engine Governors."

Tenders for Queenstown.—The Committee lately appointed by the Commissioners of Queenstown to consider the advisability of lighting Queenstown by means of the electric light recently had a meeting, at which the Chairman (Mr. Carbery) stated that he had obtained an estimate from a London company, who undertook to provide 40 are lamps, with accessories, for £3,070. At present the town was lighted by 130 gas lamps, at a cost of £460 for gas alone. These lamps did not yield a light of more than 12 or 15 candles each—say, £2,180 candles altogether—while the 40 electric lamps would give a light equal to 80,000 candles. The Commissioners having this plant in their own hands, the supply of private consumers would be a very simple matter. So that instead of paying £460 a year for an illuminant, they would acquire a realisable asset capable of great extension. It was decided that tenders for the lighting of the town should be advertised for, such tenders to be considered by the Commissioners at their July meeting. The tenders are required for the public lighting of the streets, and also separate tenders for private lighting for the Queenstown Town Commissioners. Tenders are to be sent to Mr James Ahern, Town Hall, Queenstown, by July 2nd.

Detroit Lighting Station.—Probably the most unique example of electric lighting is to be met with in Detroit. The entire city of Detroit, embracing 21 square miles, is wholly lighted by the tower system, and has been for four years past. The electric lighting plant, considered the most extensive in the world, is owned by the Brush Electric Light Company, and the whole is operated from one central station, many of the circuits being more than 25 miles in length. The Brush Company's works are of brick, and very extensive. A large boiler room, 150ft. by 55ft., has ten boilers, and a railway switch track runs through in front of the boilers. Adjacent to this is a room 45ft. by 65ft. for large engines, in which there are two Wright-Corliss engines, 20in. by 12in. each, and one Cummer engine, 18in. by 36in. Beyond this again is a two-storey brick building, the first floor being devoted wholly to engines, and the second storey to dynamo machines. This building is 55ft. by 105ft., and the lower floor opens into the large engine-room above named throughout its whole length. The station is considered a

model structure, and has a capacity for 3,000 arc lights. There are employed for public lighting 122 towers of 150ft. each, with interior elevators, whereby the lamp trimmer ascends to attend to his lamps. The tower stands on a single pillar at the base, 14ft high, and above this is a straight trussed triangular structure.

Gas and Ventilation—At the meeting of the London Section of the Society of Chemical Industry on Monday last week, Mr. Lewis T. Wright, F.C.S., A.M.I.C.E., general manager of the Nottingham Corporation Gas Department, read a paper on "The Present Position and Prospects of the Coal Gas Industry," in which he said that in the majority of cases the best burners for the ventilation systems of lighting were the regenerative ones. Regenerative gas lamps certainly required more attention than open burners; but this question of ventilating systems of lighting with intense burners was one that the gas industry itself had to solve. For the want of some efficient plan of this kind, electric lighting was displacing gas in many important installations—the sort of lighting that formed the backbone of the business, and would do so to a larger extent in the future. Gas undertakings themselves must engage in this matter; but it could not be done with any final advantage with the present staff. A new element would have to be introduced—an admixture of the architect and ventilating engineer. Speaking in regard to the cost of electric lighting, the author said it was impossible to secure a practical basis of comparison. He referred to the schedule of rates of an American electric lighting company, where the light was supplied on a time basis; and assuming the candle power of the lamps to be equal to that stated by the undertakers, the cost per 1,000 candles per hour, supposing also the consumers worked the full time allowed under the particular rates, ranged from 8.3d. to considerably over 30d., according to the length of time the light was employed.

Pier-head Gas Lighter.—Mr. George Keillor, of Nairn, has adopted one of Messrs. Woodhouse and Rawson's electric gas lighters to the large Bray's gas burner on the Nairn pier with great success. In October, 1885, the lamp was lighted and registered as a coast light. Notwithstanding the fact that the light was all that could be desired, Mr. Keillor's troubles began. All went well until the first storm came on. The lamplighter dared not venture to the point of the pier to light the lamp, as the waves were washing over the structures; and yet it was just on such a night as that the light was needed. To avoid going to the point of the pier, Mr. Keillor arranged a burner with bye pass, so as to burn at a low point all day; but, unfortunately, it only acted in ordinary weather, and was often blown out during the day. Besides, another great objection was the gas burning all day. This led him to adopt the electric gas-lighter, which he continued with an ordinary Bruce-Peebles meter governor. Mr. Keillor describes how he managed to do without carrying a wire all the 500 yards to the point of the pier. He fitted a wooden box to the lamp-post at the pier-head, and he placed the battery in lower part of box. In the upper part he fixed one of D. Bruce Peeble's two-light mercurial governors, to which the gas pipe going to lamp was attached. He then took the wire from the carbon of battery, and connected it to the brass spindle of bell of governor. The wires from the lighter in the lamp were taken down to the governor, and fitted horizontally across the cover of governor in such a way as to keep them a quarter of an inch apart—the one above the other, the

lighting wire being uppermost. The wire fixed to bell of governor he placed at right angles to the other wires, so as to go through between them about half-an-inch. When the governor was at its full height, the wire from latter pressed hard against the top on the lighting wire, and the current was connected, and when the governor was at its lowest point contact ceased. By this arrangement the pier-head lamp was lighted.

About Patents. Edison has been writing to the *American Carpenter and Builder* on the subject of patents, and gives it as the result of his experience that while it is a good thing to secure a patent, it is better to have a secret process. He says:—"The present law is a constant temptation to rascals. Under it the infringer of a patent is not interfered with until the real owner can show that he has the monopoly of the device in question. The process may take years, during which the infringer who has money and audacity enough to seize another man's invention can wear the rightful owner's life out by litigation and annoyance. I have had so much of this sort of thing within the last five years, that I have almost made up my mind never to take out another patent until the law is changed. The burden of proof is now put entirely upon the man who wishes to infringe it, whereas it ought to be all the other way. There is scarcely any invention of importance made within the last generation which has not been disputed upon frivolous grounds, and the inventor put to all sorts of annoyance. In my own case I am sure that no matter what I may patent someone will come up as soon as the patent is seen to have any value, and show by dozens of witnesses, if necessary, that he is the rightful owner of the invention. If I patent to-morrow a process for making good flour at a cost of two cents a barrel, the publication of my patent would bring out about ten men who could prove that they did that sort of thing years ago, and that I had no right to patent. In the case of my dynamo, I have patents by the score, and yet when a great firm of machinists want to go into the business of making dynamos, they coolly appropriate one hundred of my inventions, and laugh at my claim as patentee. To litigate the matter to the end, if there was any end in sight, would cost hundreds of thousands of dollars and put me in hot water for some years to come. I am an inventor and not a lawyer, and I hate litigation. If patents are going to give me nothing but lawsuits, I don't want any more of them. I am so thoroughly convinced of the uselessness of patents that one of my objects in building my present laboratory is to search for trade secrets that require no patents, and may be sources of profit until someone else discovers them. There are scores of such secret processes which are enormously profitable, and which are not claimed right and left just because they are secrets. Some are used in this country, but most of them—chemical, chiefly—are held in Europe. Methods of dyeing, of working certain fabrics, &c., pay millions every year to those who know the secrets employed. I have one chemical device which promises to pay me handsomely, and the patent office will never hear anything about it. To apply for a patent would simply invite a lot of rogues to share with me, or, what is more likely, to take all the profits. I am rather curious to see what is to be done when the phonograph comes out. The patent has only five years to run, and evidently if men with millions behind them jump into the manufacture upon a large scale, the patent may run out before my claim to the fundamental device is allowed."

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, B.S.C., F.R.S.E.

(Continued from page 463.)

MEASUREMENT OF RESISTANCES.

Differential Galvanometer Method.—The differential galvanometer has been already referred to as having, in some cases, advantages over the ordinary one. One of these advantages is the present application, in which its two coils are virtually used to form two sides of the Wheatstone's bridge. The peculiarity of the differential galvanometer and its mode of construction and adjustment will be fully referred to later. It consists essentially of two coils, which are so arranged relatively to a magnetic needle that when a current is passed through the coils they tend to turn the needle in opposite directions. It is usually so adjusted that the coils have equal resistance, and that, when equal currents flow through them, their combined effect on the needle is nil. Consider the arrangement shown in Fig. 22, in which a and b represent the coils of the galvanometer, d a box of resistances, and c a conductor, the resistance of which is required. The coil, a , and the conductor, c , are connected in series, and so also are the coil, b , and the resistance box, d . These two pairs of conductors are connected in parallel, and form part of a circuit, through which a current from the battery, B , can be made to flow either in one direction or the other by means of the reversing-key, K .

Fig. 22.

If now the resistance of a is equal to the resistance of b , and the resistance of c be equal to that of d , then resistances $a + c = b + d$, and the same current will flow through these two branches of the circuit. But when, and only when, equal currents flow through a and b , no deflection is produced, and the resistance of a is made equal to that of b . Hence, when no deflection is produced, the resistance of c is the same as that of d . There may be sensible disturbance of the result in this, as in most other resistance tests, due to thermo-electromotive force in one of the parallel circuits and not in the other, or due to different electromotive forces in these two circuits. The effect is never great when the difference of potential between the two ends, A and C , of the parallel circuits produced by the battery, B , is comparable with a volt, and it is almost completely compensated for by taking the mean of the results obtained with opposite currents. As has been remarked above, the coils a and b are equivalent to two of the resistances, in the quadrilateral of resistances, forming part of the Wheatstone's bridge. This will become evident, if we imagine another galvanometer connected across between the terminals, D and E , of the differential galvanometers which are joined to c and d . When equal currents are flowing through a and b , and consequently when c is equal to d , no deflection will be produced on this second galvanometer. It, in fact, occupies the position in which the galvanometer is usually placed in the Wheatstone's bridge. In the differential galvanometer method the equality of the current in the two arms of

the bridge is directly tested; in Wheatstone's method their equality is inferred from the equality of potential at the points D and E . In both cases the galvanometric indication depends on the difference of currents in a and b , and with suitable instruments the sensibilities are similar. The case just considered corresponds to the Wheatstone's bridge with all the four resistances of the quadrilateral equal, and for this case the differential galvanometer is particularly well suited. When the resistance d cannot be made equal to c , one coil of the galvanometer requires to be shunted, and this case will now be considered; it is decidedly less favourable to the differential method. Suppose the resistance of c to be larger than can be got from the box d . A shunt circuit may be connected between the points A and E , as shown at S in Fig. 22, so as to take part of the current which would otherwise flow through b . Let the resistance of the shunt circuit be $1/9$ of b , then, since the whole of the current which flows through a and b must flow through d , and the current through a must be nine times that through b , ten times as much current must flow through d as flows through b . But, as was explained in the previous case, the potential at D must be the same as that at E , and the junction C is common to c and d ; therefore, by Ohm's law, the resistance of d must be one-tenth of that of c . This gives a ratio of ten to one between c and d , and the same principle applies for any other ratio. Thus, if the resistance of s be made $1/99$ of that of b , the ratio would be one hundred to one, or, if instead of putting the shunt between A and E it had been put between A and D , the ratio would have been one to ten or one to one hundred, as the case might be, thus suiting low values of c . Theoretically, then, so far as mere arrangement is concerned, any resistance may be measured against a box of resistances, such as d , by means of a differential galvanometer. There are, however, other considerations which show this arrangement to be undesirable when high accuracy is desired. In the first place, the maximum current that can be sent through the coils of the galvanometer and the resistance-box is not great, and hence it is evident that when b is shunted, and consequently the current in d is greater than that in c , a very small current must flow through a and c . Small percentage change of this current cannot therefore produce much deflection of the galvanometer-needle. The same is the case when a is shunted, unless c be capable of carrying a strong current without heating much. It is then clear that as the ratio is increased, the sensibility is diminished in about the same proportion. In the second place, it is extremely difficult to insure that the ratio of the resistance of the shunted coil to that of the shunt will remain constant during the passage of the current for even the short time required to make the measurement. The current is not, of course, kept constantly flowing through the circuit, but several adjustments have almost always to be made before a balance is obtained, and this usually produced unequal heating in the coil and shunt, giving rise to a very sensible error. The very common practice of making the galvanometer coils of copper wire, and the shunt coils of German silver, may be noticed in this connection. If it were possible to estimate accurately the temperature of the coils of the instrument and of the shunt at any time, this practice would serve perfectly well, as, in that case, the ratio of shunt to coil could always be calculated from the equation, ratio = $\frac{G \times 1 + c(t' - t)}{S \times 1 + c'(t' - t)}$ where G is the resistance of the galvanometer coil at temperature t , and c the coefficient of its variation with temperature; S the resistance of the shunt at temperature t , and c' its coefficient of variation with temperature, t the temperature of the galvanometer coil, and t' that of the shunt at the time of the experiment. The temperature t and t' cannot be estimated with sufficient accuracy, and hence it is better to make the shunt coils of the same wire as the coils of the instrument. In order to obtain perfectly satisfactory results, even when the same kind of wire is used for the coils and for the shunt, it is still necessary to insure that t' shall be equal to t , and hence the shunt made for a galvanometer should be coils of the same size and shape, made of the same length of the same wire, and exposed to precisely similar conditions for cooling as the instrument coils are exposed to. These conditions never are, and cannot con-

veniently be, complied with in practice, and, in consequence, shunts should be avoided as much as possible in all measurements requiring a high degree of accuracy. For the measurement of very high resistances the coils of the galvanometer may have very considerable resistance without greatly altering the sensibility. In such cases the coils of the galvanometer and the shunts can be advantageously wound with German silver or platinoid wire. The very small variation of the resistance of these metals with change of temperature renders it possible in such cases to obtain considerable constancy and accuracy in the shunt ratio. For some special purposes, where the resistances are not very high compared with the resistance of a platinoid coil, better results may be obtained by using wire of phosphor bronze or aluminium bronze, all of which have a much lower temperature variation than pure copper. In all cases where the resistance of the galvanometer greatly influences the sensibility of the arrangement the galvanometer coil should be made of wire of pure copper. No advantage is obtained in this case by using an alloy, the resistance of which varies little with temperature, because the smaller the temperature variation the higher is the specific resistance in very nearly the same proportion. Greater battery power must therefore be used to obtain the same sensibility, and consequently the heating is just about as much greater as the temperature variation per degree is less. When lower sensibility is sufficient, it is usually better either to use less battery power or fewer turns of thicker copper wire in the coils thus by lower resistance insuring less heating. It is important to bear in mind that the answer to the question as to what metal may be used in the coils of a differential galvanometer to be used for the measurement of resistances is always obtained from a consideration of sensibility and possible electromotive force, other than that of the testing battery, which may exist in any part of the circuit. The sensibility must be such that the resistance may be measured to the required degree of accuracy, and for most purposes it should be such that a difference of one ten-thousandth between the currents in the two coils can be detected. Possible disturbance due to thermo electric effect at junctions or other causes renders it necessary that the electromotive force used in the test should be much higher than any other which is likely to be in the circuit. When an unshunted galvanometer is used, an electromotive force between A and C of one or two volts is sufficient to avoid much error from this cause in almost all tests with the exception of telegraph line testing. When a shunted galvanometer is used, the electromotive force on the galvanometer coils themselves should be one or two volts. With good galvanometers having suspended needle systems, and especially with reflecting galvanometers, there is no difficulty in obtaining the required sensibility when such an electromotive force is kept on their terminals, and hence they should in all cases be made of wire having a low variation of resistance with temperature. The question of the choice between wires of different material for galvanometric purposes will be more fully and more advantageously discussed under the head of "Voltmeters."

(To be continued.)

PRACTICAL ELECTRICAL UNITS.

BY W. E. FESSON.

(Concluded from page 321.)

In the last article we considered the way in which dynamo and engine trials should be conducted, and observed that under the usual conditions of installation working we might expect 70 per cent. or so of the power indicated in the engine cylinders returned at the dynamo terminals.

It may be thought that the discussion of such questions is beyond the scope of articles professing to deal with electrical units, but, after all, the most important consideration is the price we have to pay for our units. Where electric lighting is concerned the coal bill is the all-important item in expenditure, and no excuse is therefore needed for bringing to the notice of the reader some further considerations regarding the circumstances on which its magnitude depends.

Boilers of the locomotive type are now largely employed for installation work, for which they possess special advantages. Steam can be raised rapidly with them when at work, and the expensive setting a large item in putting down Lancashire boilers is saved with this type. Their performance depends greatly on the way in which they are treated, and with good stoking it is possible to obtain first-class results; but the author's experience shows that a certain time must be served to attain proficiency even in stoking a boiler furnace. A man accustomed to Lancashire boilers generally has no idea of locomotive boilers, and none succeed so well with them as those who have been railway stokers. In ordinary working, a locomotive type boiler should, with good management, convert into steam at 120 lb. pressure rather more than 9 lb. of water per pound of Welsh coal consumed, the feed water being supplied at a temperature of 60 deg. F. As a matter of fact, an evaporation considerably over this amount has been frequently obtained; but if from year's end to year's end 9 lb. are reached, the evaporative performance is all that can be fairly expected.

The amount of steam consumed per i.h.p. hour varies a good deal in different engines, and varies greatly in the same engine for different loads. Speaking generally, a non-condensing compound engine, loaded from two and a half to three times its nominal h.p., will consume per i.h.p. hour from 20 lb. to 24 lb. of steam at 120 lb. pressure. We are not now speaking of competitive trials lasting for four or five hours, but of regular daily working. For this 22 lb. is a fair amount on which to reckon, there being plenty of makers ready to supply engines which will not use more. Though the steam used per i.h.p. hours is diminished as the load is diminished, other circumstances arise to counter-balance this as we shall see presently. Meanwhile, we may assume that while running we consume $\frac{22}{9} = 2.44$ lb. of coal per i.h.p. hour.

When we make inquiries regarding the ratio of the power actually delivered at the crank shaft to the power indicated in the cylinders, the makers are far from ready to offer guarantees. As a matter of fact, very few makers know what their engines are capable of doing in this sense. They suppose they will give a brake h.p. of from 75 to 80 per cent. of the i.h.p., though in the absence of brake tests they cannot exactly say. Generally, the engine-building fraternity regard electric light men as a nuisance because they want to know too much. The former have put in, they will tell us, tens of thousands of h.p. with never a question asked regarding the ratio referred to, and now, forsooth, they go on because you want to light the mill, in which we have already placed engines of 2,000 h.p., by an engine of 100 horse or so; you would coolly put us to no end of trouble in rigging up absorption dynamometers. There is much to be said from the engine builders' point of view, as the testing by brake of large engines is a very troublesome operation, but it is satisfactory to know that where tests have been made with brake and indicator simultaneously, the results have shown that from compound engines, loaded to two and a half or three times their nominal h.p., a net return on the brake of from 85 to 90 per cent. of the i.h.p. is obtained. This percentage increases as the load is increased, but, on the other hand, the steam used per i.h.p. also increases. The load stated is that for maximum economy, and we may, therefore, in ordinary working, reckon on a mean consumption of about 2.75 lb. of coal per brake h.p. hour. It should be mentioned that at the recent competitive trial of engines at Newcastle the consumption was less than three-quarters of the above amount. But of course everything was then in first class trim, and the trial maintained but for a few hours.

18. *Efficiency of the Dynamos.*—By the commercial efficiency of the dynamo is expressed the ratio between the electrical power appearing at its terminals and the mechanical power given to its pulley. Small dynamos by good makers may be reckoned to give a commercial efficiency of 85 per cent., while large machines may give 90 per cent. or even more. Since the armature and magnets have a certain resistance, there is always some electrical energy spent in the machine itself, and not available for use externally. The energy appearing between the terminals is in consequence from 90 to 95 per cent. of the total

electrical energy converted, and the ratio of the first quantity to the second quantity is termed the *electrical efficiency* of the machine. There is also power wasted in friction of bearings due to the weight of the armature in friction of brushes, in magnetic friction, and in generating parasitic currents. The whole of the energy applied to the pulley is not in consequence converted into electricity. To the ratio between the total energy converted and the amount given to the pulley the term *commercial efficiency* has been given. Until recently it was customary to measure by some form of transmission dynamometer the power given to the machine, but this method has been now abandoned in favour of methods in which the measurements are mostly or wholly electrical. Dr. Hopkinson's method consists in driving by a belt two similar machines, the shafts of which are coupled in line, one machine acting as a generator, and the other as a motor. In this way the greater part of the power driving the former is supplied by the latter, and only an amount equal to that expended in losses inside the two machines is furnished from an external source. The power thus furnished is measured by a transmission dynamometer, and the advantage of the method lies in the fact that this measurement—the only one about which there is any uncertainty—is a small fraction of the total power supplied, all other measurements being electrical. The liability to error of observation is therefore largely reduced, not to speak of advantages accruing from the possibility of testing large machines with a trifling consumption of steam. The accuracy of the method depends on the assumption that the losses arising from magnetic friction and parasitic currents are equal in generator and motor, though from the necessity of the magnetic fields being of unequal strength there must be some trifling difference in these. But while a small error is possible in the apportionment of the losses, there is no manner of doubt regarding the total efficiency of the system of generator and motor taken together, and a very great step in practical measurement was made when the method was demonstrated at the works of Messrs. Mather and Platt. A further step was made when Lord Rayleigh proposed to do away with the transmission dynamometer altogether, and furnish electrically the external power required either from a third machine or from accumulators.

But a simpler method than either of the above has been at a later date proposed by Mr. Jas. Swinburne. It may not be entirely free from theoretical objections of a minor character, but its extreme simplicity must counter-balance these, since they cannot be other than of trifling magnitude. In Dr. Hopkinson's method, two dynamos of equal size are required, in Lord Rayleigh's method there must be a third smaller dynamo, capable, however, of giving a current equal to the larger ones. In Mr. Swinburne's plan, in addition to the dynamo to be tested, a second smaller dynamo is required, which must be capable, however, of giving the same *difference of potential* as the larger one. To determine the efficiency, the field magnets of the dynamo to be tested are excited by the small machine until the armature of the former, rotating as a motor, gives a back E.M.F. equal to the E.M.F., which as a generator it would give, turning at the same speed. The armature will take a certain current depending on the magnetic and mechanical friction overcome in spinning itself round in the field, this current being furnished by the small machine. The product of the current and the back E.M.F. Mr. Swinburne calls the stray power, assuming the total electrical energy appearing when the machine is fully loaded, *plus* the stray power, to be equal to the mechanical energy given to the pulley. Calling the stray power A, the loss due to the electrical resistances of the machine B, and the energy appearing at the terminals C, we have—

$$\text{Conversion efficiency} = \frac{B + C}{A + B + C}$$

$$\text{Electrical efficiency} = \frac{C}{B + C}$$

$$\text{Commercial efficiency} = \frac{C}{A + B + C}$$

In an installation where there is a number of machines or a storage battery, the testing of the dynamo efficiency

becomes then a simple matter, and by the above method a degree of accuracy is obtained far greater than by any transmission dynamometer.

Where there exist no means of furnishing current for the measurement of the stray power, recourse must be had to transmission dynamometers, of which there have been many designed from time to time. Generally speaking, they may be divided into two classes—first, those in which the driving belt is constrained in a definite direction, the constraining forces being measured and affording an estimate of the power transmitted, secondly, those through which the power is actually distributed, being received by one pulley and transmitted by another. In the latter apparatus the torque, or turning moment, is actually measured by the extension of springs, or by the balancing of weights against it. The dynamometer designed by Von Altebeck is the best known of the former class, having been very successfully employed for testing the efficiency of dynamos by Drs. Hopkinson, Prof. Adams, and others.

Fig. 1

The sketch, Fig. 1, shows one form of the apparatus, E being the countershaft pulley and D that of the dynamo. A and B are two pulleys, mounted on the triangular frame A, B, C, which is free to move on a centre, C. If the motion is in the direction of the arrow, the bottom side of the belt being in consequence the driving side, it is easy to see that there exists a force tending to pull B and C downwards from the position shown. This force is counteracted by pulling A, B, C up, the pointer attached thereto being always kept at the zero position. A spring balance, S, indicates the force necessary to maintain the pointer at zero, and knowing this, the dimensions and the angles the belt makes, we can either trigonometrically or graphically determine from the triangle of forces the difference of pull on the two sides of the belt. A dynamometer of the form shown in the sketch can be made and rigged up with little trouble, but in its improved form the apparatus is self-contained, having the pulleys, springs, and index all mounted on a frame, which, being provided with guide pulleys, can be fixed firmly down to the floor when used for testing. There seems to be considerable difference of opinion as regards the accuracy obtainable with this dynamometer. In the hands of an expert who knows it thoroughly, reliable results may be obtained; but, on the other hand, great difficulties have been experienced from time to time by those who have not had previous practice with the apparatus. Many dynamometers on the same principle have been designed, but it is unnecessary to notice them here. In all the belt or rope is constrained to take a particular direction round pulleys, and the constraining force being measured, the difference of tension on the two sides of the belt can be therefrom determined. The difference in pounds, multiplied by the belt velocity in feet per minute and divided by 33,000, gives the h.p. given to the machine.

One of the best known dynamometers, belonging to the second class, is White's. This apparatus, Fig. 2, consists of three mitre wheels, A, B, C, as on sketch; A and C being attached to the pulleys, D and E, which are gun-

metal bushed and free to turn on a pin, *a, b*. The mitre wheel, *B*, turns on a pin attached to the sleeve, *F*, the latter also free to turn on *a, b*. Prolonged to both sides of *B* is the lever, *L*, this and wheel being balanced by a counterweight, *W*. The action of the dynamometer is as follows. Suppose it to be interposed between the counter shaft and the dynamo, the belt from the former running on *D* and to the latter on *E*, the power being thus transmitted from *D* to *E* through *B*. If the motion is in the direction

Fig 2.

of the arrows there is a tendency to lift *B*, and this must be counteracted by a weight, *P*, placed on *L*. When the lifting force is balanced, the h.p. transmitted is evidently obtained by multiplying half the value of *P* in pounds into the distance in feet of *P*, from the centre of *a, b*, into the revolutions by 2π , and dividing by 33,000. Put in the form of an equation—

$$\text{H.P.} = \frac{P \times R \times \pi \times n}{33,000}$$

where *R* is the distance from *P* to the centre of *a, b*, and *n* the number of revolutions per minute. A modification of this dynamometer, proposed by the author, and which he considers an improvement, consists in substituting for the sleeve, *F*, and lever, *L*, a pulley, in the web of which the wheel, *B*, is mounted. A band is half wound round and attached to the rim of this pulley, its other end being fixed to a spring balance. The other end of the spring balance is fixed, and since for every load the pulley takes up a definite position, the value of *P* is at once indicated on the spring balance without the trouble of adjusting weights or maintaining the wheel, *B*—always in the same position. There are a great many forms of dynamometers belonging to the second class, which space will not allow us to describe here.

19. *Conclusion.*—We have considered the measurement of the power given to the dynamo, but the measurement of the power absorbed by countershafting is not such an easy matter. It must be noted that, whereas in measuring the efficiency of the dynamos by electrical methods we have excluded the friction due to the pull of the belt on the bearings, in the transmission dynamometer method this is necessarily included. It is evident that a correct measurement of the power absorbed by the countershafting can be obtained if we know the efficiency of the dynamo, and the ratio of brake to indicated h.p. given by the engine, but in the absence of such knowledge, unless we interpose a transmission dynamometer of some kind, our estimate of the power absorbed must be mere guesswork. The determination is difficult because the friction of engines or shafting loaded is a very different thing to their friction unloaded. It is a common practice to indicate the engines running idle, again driving the countershafting, and, thirdly, with the dynamos giving their full output, and to assume that from these indications we get the power absorbed by engine and shafting respectively when loaded. But this is incorrect, for when loaded the power absorbed in engine and shafting will increase, and the difference shown between the second and third indications will in consequence diminish. It has been proposed to employ as a dynamometer a steel rod of small diameter, which would form part of the shafting, and

indicate by the twist produced on it the power transmitted; but the author is not aware of any results obtained from this form of dynamometer having been published. If we are content to treat the engine friction and friction of the shafting as one quantity, the power wasted is simply the difference between the i.h.p. and the h.p. received by the dynamo, and knowing the efficiency of the latter the determination is immediately arrived at, but if we wish to split this quantity into its two components for engine and shafting respectively, the determination must be necessarily a rather troublesome one. From the rough experiments which have been made, the power lost in the countershafting and belting—i.e., from the engine fly-wheel to the dynamo pulleys, including the friction due to the pull of the belt on the latter—is from 10 to 12 per cent. of the engine brake h.p. Of course there must be great differences in different installations, but generally speaking and we can only speak generally on such a subject the above may be considered a fair estimate for these losses. It appears, then, that from a first class compound engine and dynamo coupled direct an electrical return of 80 per cent. of the i.h.p. can be obtained. As before mentioned, this has been surpassed. From dynamos belted through countershafting a return of 70 per cent. may be confidently expected in ordinary working, while from those directly belted to the engine fly wheel the return may be fairly assumed to lie between the two at 75 per cent.

THE TRANSMISSION OF ELECTRIC POWER.

BY HERR CÖRPER.

In the *Centralblatt für Elektrotechnik*, Herr Cörper has described the Helios motor and system, also in the *Street Railway Gazette*, and from these the following abstract is taken:—

The employment of electrical propulsion for cars is more and more drawing to the front. In America, already in twenty towns there are electrical railways being worked. In England extensive trials are being made. On the European continent some lines are in activity, and last year the general attention of tramway companies was called to electrical gear, as the most convenient, elegant and cheapest means of locomotion, by an address by M. Michelet at Brussels.

According as the electrical energy is supplied to the car in motion from outside, or carried along with it in storage batteries, there are three questions to be solved. In the former case these are to be ascertained: the best way of supplying the current, the best construction of the motor, and a reliable kind of transmission between motor and car. In the second case these are to be found out the best accumulator, motor, and transmission gear. I only intend to submit some remarks on the motor, the gear, and the accumulators.

Hitherto, almost exclusively, dynamos of high speed of the most varied construction have been employed as motors. They are usually fastened to the car frame, and transmit their power to the axle of the car by means of toothed wheels, friction wheels, belts, chains, wire spirals, worm wheels, gearing, &c. Immisch and Holt fasten the motor to the axle of the car, which is immovable, whilst the wheels run upon collar boxes. The one wheel is connected with a toothed crown wheel, into which the small tooth wheel upon the axle of the dynamo fits. This gearing, however, does not answer, and in consequence a new method is being tried. From the search after the best construction of the motors, and the changing of methods of transmission, it can easily be seen that a thoroughly satisfactory solution of these questions has not been found. The reason for this lies in the nature of the matter itself. Only in the rarest cases with electrical tramways an uninterrupted run to a strictly defined distance can be taken into account. In such cases the management as it exists in the line near Schwabing may conveniently be resorted to, where the car at the terminus runs up an incline 18 metres long, is arrested at the top, and when restarting attains, by running down freely, a higher velocity before the electro-motor is set at work. Mostly, however,

a similar arrangement is impossible, because the car is obliged to frequently stop and restart without any regard to the construction of the line. Then the greatest efforts under the most unfavourable circumstances are asked from the motor. A firm coupling between motor and the axle of the car, for mechanical reasons, appears unavoidable, be it by tooth wheels, belts, worm-wheel gearing, or similar means.

Trials which were executed upon a line which was in the very best state and quite level, have resulted in proving that a certain car which, when in motion, will go over a distance of five metres per second with a traction-force of 120 kilogramme metre seconds, requires 315 kilogranne metre seconds for starting. With a worse state of the line, with risings, in curves, or when unevenly loaded, this proportion is more unfavourable. The electrical motor consequently, in order to comply with the requirements of working, ought to develop the greatest power when starting. This, however, with all constructions hitherto devised, is not the case. If the current, when the car stops, is made to circulate, the motor, in consequence of its firm coupling with the propelling axle, cannot but start very slowly. The supply of current, although such an excessive one, that the insulation is endangered, and the sparking upon the commutator great, nevertheless yields to the motor but a small fraction of the power which it develops with the normal number of revolutions and less current. The electrical tramway, as it has hitherto been constructed, therefore starts under the most unfavourable circumstances, and only when a certain speed of the car has been reached, the motor works with little current and greatest power. This, again, however, is just the stage of the working where the least force is necessary.

Furthermore, an inconvenience of the present arrangement arises from the mode of transmission. It is well known how great is the loss of power with worm-wheel and tooth wheel gearing; not much less is the same with chain and friction gearings. The rapid depreciation of the single parts of such constructions, though made of the hardest and toughest material, sufficiently proves what power is lost thereby. Belts, wire spirals, &c., also show a considerable loss of force. This loss becomes the heavier the greater the speed of the motor. The inferior safety of the working offered by the accustomed modes of transmission, is also to be considered. It is known that interruptions are daily occurrences, that the expenses of repairs are very considerable, and that the interruptions of the working consequent upon the failure of the arrangements for transmission are regularly being attributed to the electrical parts generally, and not to the defective mechanical arrangements.

If we resume the practical results of the constructions hitherto used, we find that the motor must work under the most unfavourable circumstances when starting; that it has the least power and requires the most current when it requires the greatest power; that it develops the greatest power when it requires the least; that the mode of transmission entails a considerable loss of force, which happens to be greatest just when the least power is necessary; and that the mode of transmission is not only insecure, but also detrimental and very expensive.

If the propulsion takes place by accumulators, then the frequent damage which they are exposed to is to be taken into account. An accumulator is almost undestroyable, if the same is correctly charged and discharged. Every possible effort has been made to improve the accumulators, so as to make them fit for being used for tramways. Every good accumulator is suitable for this purpose. It is only necessary to not overwork it unreasonably. This, however, as long as the present constructions of motors and transmissions are being employed, always takes place as a matter of course.

Nothing hurts the accumulator more than a short circuit. When starting, however, if the motor is firmly coupled to the axle, the accumulator is short circuited, because the current which feeds the firmly fixed motor is only moderated by the resistance of the copper, and not by the counter E.M.F. which the motor displays when it runs with the normal number of revolutions. It is an easy matter for the present state of the technical science to construct an accumulator for a run of 50 kilometres and to place it upon

a car, but it is a thoroughly useless endeavour to improve the accumulator so as to make it stand being exposed to a short circuit, perhaps 50 to 100 times during a 50 kilometre run, as the working requires. Hereby the accumulators simply get out of order, just as well as the motor gets overheated and its commutator damaged by the fire on the brushes.

All these circumstances, which under the present arrangements offer the very opposite to what the electric working of railways needs, point with irresistible force to a fundamental change of the constructions, if the future shall see progress in the electric railway. If there were no electric railways existing, the machine-maker would perhaps propose the following programme. —

1. The motor must, according to the requirements of the working, display its maximum power when the car starts.
2. The transmission by means of worm-wheel gearing, tooth-wheel gearing, chains, &c., cannot be admitted on account of the great wear and tear, the insecurity of the working, and the loss of power.
3. The accumulator and the motor must not be exposed to short circuits, because hereby the accumulator is destroyed, and the motor becomes endangered by overheating.

From these points of view, the arrangement as subsequently described here has been constructed. It can be readily understood by careful observation of the reference letters on the accompanying cuts.

FIG. 1.

FIG. 2.

The magnetic field of the motor, *C*, is fixed upon the axle of the car (the propelling axle) itself, so that a turning of the magnetic field also involves a turning of the axle of the car. The armature shaft, *d*, with the brake-disc, *e*, is placed on a ram's-eye, *f*, which, by means of collar boxes, easily movable, is mounted upon the axle. The magnetic field bears the springs, *g*, where, as underneath these spring (*g*) the commutator, *h*, is fastened to the brake-disc, firmly connected with the armature shaft. Upon the outer ram's-eye of the brake-disc, *e*, there are placed two friction rings, *i*, by which the current is conducted to the armature, whilst near the magnetic field, *C*, upon the propelling axle, there are likewise placed grinding-rings (*k*), by which the conduct of current to and fro the magnetic field takes place. Upon the magnetic wheel, *b*, and the brake-disc, *e*, a speed-reducing gear, *l* and *m*, is attached, which, by means of a lever, *n*, is handled by the engineer of the car. If the lever (*n*) is turned to the left (I), then, by pushing the brake-block, *m*, against the brake-disc, *e*, and the brake-disc, *e*, and the armature connected therewith, is arrested; vice versa, if the lever is turned to the right (II), then the car-wheel, *b*, becomes arrested, the brake-disc, *e*, connected with the armature, is completely

liberated, allowing the armature to turn perfectly freely. According to very accurate trials, made by myself, an electro-motor fitly constructed makes, with uniform supply of current, the same number of revolutions, no matter whether the magnetic field or the armature is made to turn. If armature and magnetic field are left to run simultaneously, both only make half the number of revolutions, whilst running in opposite directions. If, therefore, the axle, *a*, rests in boxes, *b*, one can, by arresting the armature, *d*, make the propelling power be exercised by the magnetic field, *c*, alone, or one can, by moderating the speed of revolutions of the armature, *d*, give to the magnetic field, *c*, and along with it to the propelling axle, *a*, proportionate velocity.

The effect now of the described arrangement is as follows: When the car stops, the brake upon the car must have been racked. Hereby the brake disc, *e*, and the armature, *d*, are liberated. If the current circuit is now closed, the armature will at once attain its normal speed, because it can turn freely. A short circuit of the machine, or the accumulators, is therefore impossible. If the armature has its normal speed, the dynamo also develops its greatest power with proportionately little consumption of current. Should the car be started, the engineer must let the car wheel be free. He therefore turns the brake-lever to the right. Hereby he arrests the brake-disc, *e*, and with it the armature, *d*. In the same proportion, however, as the speed of the armature, *d*, is slackened, the magnetic field, *c*, commences to turn, viz., in the opposite direction, so that finally when the brake block, *m*, completely arrests the brake-disc, *e*, and with it the armature, *d*, then the magnetic field, *c*, alone propels the car with normal velocity. Should it be stopped, the engineer must turn the brake-lever to the left (1). Thereby he unites the armature, and because the same at once tends to take up the normal speed, not having to exercise any power, the traction force of the magnetic field at once ceases, and the brake can without hindrance stop the car-wheel.

It is clear that the braking gear can be varied in the most manifold manner, also be replaced by conical and other brakes. The predominating idea of this arrangement always remains this: *The firm connection of one of the elements of the machine with the propelling axle and the freely movable arrangement of the other element of the motor, controllable by a special braking gear.* The driving forward and backward is effected by changing the direction of the current to the armature. If we examine how far the described construction responds to the programme set up we find:—

1. The motor obtains when the current is closed, even if the car stops, at once its normal speed. It disposes, therefore, of its maximum power at the moment when the car, by pressing the brake upon the armature braking disc, starts.
2. All intermediate gearing for transmission is obviated, because the motor is fastened to the car-axle itself and because it has the same velocity as the propelling axle.
3. Neither the accumulator nor the motor can be exposed to a short circuit when starting, because, before being able to do so, the brake on the braking-disc of the armature must be opened mechanically, and because the armature afterwards is not in any way hampered to at once assume its normal speed.

Against this construction there can be objected that the brushes or friction springs must turn round along with the magnetic field, and that the dynamo, because fastened to the propelling axle, can have but an inferior velocity, and consequently thereupon have but inferior efficiency. The first objection appears futile, because, whilst the train runs, it would not be possible to attend to the brushes. It does not matter, therefore, whether the same move or are fixed. The second objection leads at once into the syllabus of modern electro-technic, of which one dogma proclaims: "Slow-speed dynamos notoriously have less efficiency than fast-speed ones." I always ask, which dynamos? The slow-speed dynamos, built by the Society Helios at Ehrenfeld, Cologne, for 80 to 120 revolutions per minute, according to my construction, all possess an electrical efficiency of more than 90 per cent. When running they hardly get warm. The copper winding has, when full current is on, but about 1 to 1.3 amperes per square millimetre sectional area of copper.

For the present the law of Ohm still rules, and according to that the current in all parts of a closed conductor is everywhere the same. According to my own practical tests, a copper wire coil of 2.3 mm. wire, when a current of 35 amperes passes it, becomes so hot that it can hardly be touched. It requires, therefore, a strong fidelity of faith, if thus constructed dynamos, which, in addition makes 1,200 revolutions, are not only mentioned in one breath with Helios machines, but as regards their efficiency are represented as far superior to the latter. It must always be asked, What machines are referred to? And as no electrician who will boldly state that fast-speed machines are better than slow speed has as yet taken the trouble to accurately examine one of the numerous practical constructions of the Helios Company, I think I have the right to say that the assertion, that high speed generally gives a better commercial efficiency, than a small number of revolutions, belongs to the domain of idle fallacies.

As things are, the objection against the employment of the slow speed motors, mounted upon the axle of a car, can fittingly be brought forward only when a bad construction is concerned. This arrangement is, however, quite unobjectionable when a good machine, fit for the purpose, is being used. In a given case, which is represented in the accompanying drawings generally, the propelling axle of a street tramway is made the object. The diameter of the wheel is 750 mm., the circumference, therefore, 2.35 metres. The car runs 300 metres per minute, from which there results a speed of 125 revolutions per minute. The dynamo for this number of revolutions is calculated as a current originating machine in series with an electrical efficiency of 86 per cent. I hardly believe that anyone, after examination of the relative circumstance in practice, would maintain that this arrangement gives an inferior commercial efficiency to any other fast speed machine, the power of which must be transmitted by tooth wheels, worm wheels, chains, &c., from the axle of the armature upon the propelling axle.

I am of opinion that only the plainest views concerning the construction of machines can lead to practically good solutions on the field of electro-technics. The chief condition is to furnish good mechanical installations and arrangements. The race and the haggle about fractions of percentages of efficiencies has little value for practical purposes.

So I believe that the introduction of electrical railways will depend on efficiency, be furthered by the simple arrangements here described, because the same evade, as far as possible, those defects which the constructions hitherto used have shown.

THE ELECTROLYSIS OF MERCURY BY THE ACTION OF AN ALTERNATING CURRENT OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Perhaps it will be of interest to some readers of your valuable paper to know of the peculiar behaviour of two mercury electrodes placed a short distance apart in dilute sulphuric acid when an alternating current of electricity is passed from one electrode to the other through the dilute sulphuric acid. As soon as a current is caused to flow, the mercury becomes agitated and presents a beautiful wavy appearance on its surface, which increases in its agitation as the current strength increases; the mercury at the same being attacked by the acid, forming an insoluble sulphate, rises with the hydrogen, which is liberated at the surface of the mercury in a cloudy form, and slowly falls to the bottom of the cell. This peculiar phenomenon is of great scientific interest, as this sulphate is formed in proportion to the current passing, consequently the mercury loses in weight in the same proportion. We made these discoveries in the course of an extended series of experiments to overcome the difficulty of measuring alternating currents. Owing, however, to many mechanical difficulties in the use of mercury, the idea to use this as a meter was abandoned. Further searches resulted in a successful issue, and we hope to shortly publish an account of the working of our meter. Yours, &c.,

LOWRIE HALL.

THE ELECTRICAL ENGINEER.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

ELECTRIC TRAMWAYS.

It is one of the tenets of political economists that as soon as a certain thing is generally wanted, production steps in and supplies that want. Applying this doctrine to electrical engineering, and especially to electric tramways, we may reasonably suppose that if it be clearly established that there is a demand for motors, gearing, batteries, conductors, and all the accessories of electric propulsion, these things can be had by the simple process of applying to those persons competent to design and construct them. The problem of electric tramways is not beyond the capacity of electrical engineers, as is amply proved by the various lines already in successful operation. The supply is fully up to the demand and more. Special systems are continuously being brought forward for which there even is no demand. Why inventors should go out of their way and design complicated pieces of apparatus to perform a certain kind of work which can perfectly well be done by simple machinery already practically tried, it is difficult to say. In all probability Mr. So-and-So's special system has been simply designed with a view to bring out some distinctive novelty, or is a fad of Mr. So-and-So's which he will find it difficult to justify before competent engineers. He may have a theory of his own by which he makes his design appear plausible to the general public, but as to giving an intelligent scientific account of the why and wherefore, such as engineers can appreciate, this is not in his line.

The total length of electrically worked roads in Great Britain was in the autumn of last year about 22 miles, and this includes a telfer line and an electric railway or two. At present the total mileage worked electrically does probably not exceed 18 miles, and if we except the Stratford and Manor Park line, none of the others have any special system, but each is designed with due regard to local requirements, and on the whole they work satisfactorily. As regards the line just mentioned, there can be little doubt that if the "special" and, to our mind, uselessly clumsy and heavy gear were replaced by the ordinary spur wheel and chain, it would be an improvement. But, after all, this system must be considered simple as compared with two others recently brought forward. The one is the Jarman system, and the other that devised by Mr. Coerper, of Cologne. The novelty of the former consists in the employment of a duplicate machine, one armature being used when the car is travelling in one direction, and the other when it is travelling in the opposite direction. This is done to prevent either armature getting too hot, a contingency which Mr. Jarman anticipates if one armature only were used continuously. Now there are many dynamos which must be kept running day and night for weeks together, and yet their armatures keep in good con-

dition. Motors are often worked for 10 and 12 hours at a stretch, and if it be remembered that upon the durability of a big transmission plant the working of a whole factory may depend, it will be easily seen that the chances of failure must be exceedingly remote, otherwise no practical engineer would take the risk of recommending, nor a shrewd business man that of adopting the electric transmission of energy for every-day commercial use. Viewed in the light of experience, Mr. Jarman's special system appears therefore to be a device to overcome a difficulty which does not exist; whilst at the same time it is more complicated than any of the designs which have already been found to answer in actual practice.

The motor and gear proposed by Mr. Coerper is also intended to overcome an imaginary difficulty—viz., that of too big a current at the start. In this design the armature is keyed on one of the car axles, and the field is capable of revolving round the same centre if not held by a brake. The theory is as follows:—In the ordinary arrangement, upon first turning on the current, the armature cannot immediately acquire its full speed, and an excessive current must pass until the car is fairly started. Now in Coerper's arrangement, although the armature cannot start any faster than the inertia of the car will permit, the field (when the brake is released) can start off in the opposite direction, and therefore the relative speed of armature and field is very quickly obtained. Consequently there is almost at once sufficient back E.M.F. to prevent the passage of an excessive current without its being necessary to insert artificial resistance into the armature circuit. The brake is then slowly tightened, thereby bringing the field gradually to rest and accelerating the armature until the full speed has been reached. All this sounds very pretty, but is misleading. To start the car in a given time—that is, to impart to it a certain acceleration—a definite torque must be exerted by the motor, and this requires a definite current through the armature. Whether the latter be revolving slowly or quickly has nothing to do with the starting power, which is simply a question of current. There is therefore nothing gained by allowing the back E.M.F. to rise at once. Mechanical work must ultimately be wasted in the friction of the brake which brings the field to rest, just as mechanical work is wasted in heating the artificial resistance inserted at the start with the motors as usually constructed. But there is this difference: in the usual type of motor the apparatus used to protect the armature from an excessive current at the start is a plain resistance coil and switch; in Coerper's improvement (?) it is a moving mechanical device entailing considerable complication.

We have alluded to these various devices, not so much to show that they present no special advan-

tages, as to point out the lesson they teach; and this lesson is that inventors are still casting about for some means by which to get "more power." When mechanical engineering was yet in its infancy, many inventors spent years of their lives in vain attempts to devise some cunning combination of mechanical elements by which to multiply power, and now it is as though some electrical engineers were pursuing a similar course. Hitherto nearly all the failures of electric propulsion have been due to the fact that the designers of the apparatus had under-estimated the power required, but the remedy should not be sought in special and complicated contrivances. There is only one remedy, and that is to make the apparatus strong enough in every detail and of ample power, whilst retaining for it the most simple forms which practice has shown to be efficient.

Now what power should be provided? The tractive force on an average tram-line, exclusive of that due to gradients, is about 25lb. per ton of rolling load. We may take the weight of a large car filled with passengers, and including the weight of motor and gear, to be from $6\frac{1}{2}$ to 7 tons, and if it contain accumulators, from $8\frac{1}{2}$ to 9 tons. These figures are slightly higher than generally assumed, but as we advocate motors and accumulators of ample size, they will not be found very wide of the mark. Assuming the speed to be 7 miles an hour, the work done on a fair, level road would be $3\frac{1}{2}$ and $4\frac{1}{2}$ h.p. respectively, or say 4 and $5\frac{1}{2}$ e.h.p. to be supplied to the motor. But the roads are not always in fair condition. The grooves of the rails are often filled with dirt, the rails are worn so that the car rolls occasionally on the flange of one wheel and the face of the other, whereby a grinding action is produced, power is also wasted on sharp curves. To provide for these contingencies an allowance of 50 per cent. at least should be made. This brings the power up to 6 and $7\frac{1}{2}$ e.h.p. respectively. A further allowance must be made for gradients. A rise of one foot in a hundred increases the tractive force required by 22·4lb. per ton. Say that the steepest part of the line is 1 in 30. In this case we would have to add another 10 and 13 h.p. respectively, making a total of 16 e.h.p. for a car worked on the conductor system, and $20\frac{1}{2}$ e.h.p. for a car worked on the battery system. These powers are not required continuously, but the machinery must be capable of supplying them at certain times. There is, however, another allowance to be made. To start a car, the tractive force exerted may rise as high as 120lb. per ton, especially if the start is made on a bad part of the road containing a sharp curve. Add another 66lb. for the rise, and we have a total of 186lb. per ton, to overcome which the motor will have to exert a torque which, at the full speed of 7 miles an hour, represents 30 and 39 e.h.p. respectively. Since these large powers have only to be supplied for very short intervals, it is not

necessary that the wire on the armature and the series wire on the field should be designed to continuously carry the corresponding currents. It is quite admissible to send for a few seconds three times the normal current through the motor, so that a 10 and 13 e.h.p. motor respectively will be ample to do the work. But the gear and all the mechanical parts of the machinery must be strong enough to stand the sudden heavy strain, corresponding to 30 and 39 e.h.p. We have given the above figures, merely by way of example, to show the amount of power which may be required for electric tramcars. The figures will have to be modified according to local circumstances. The sooner electrical engineers realise the exact amount of power required, and provide accordingly, the better. We shall then hear no more of failures, and the special systems of the faddists will vanish. There is no difficulty or mystery about electric tramcars. Any trained electrical engineer is competent to produce a thoroughly workable design, and that without becoming indebted to the inventor of any of the special systems. But to ensure success we must leave his hands free, and allow him to design the machinery in accordance with the special requirements of each case.

CORRESPONDENCE.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR, —Mr. Jarman seems to have misunderstood my argument about his double armatures. It is distinctly stated in the report, that one armature is used for propelling the car on the outward, and the other on the return journey. If then the armatures were perfectly cool at the end of each journey, where is the necessity for double armatures, and if both armatures are used at the same time, where is the duplication of the motor? My experience with electromotors for tramway work—which has been with continually running heavily-loaded cars, and not a mere experimental run with a fabulous report thereon—has convinced me that if the car, motor, &c., has been designed by anyone who knows anything about them, the heating of the armature need not be taken into consideration. All armatures, of course, heat a little, but not, if properly designed, to the extent mentioned by Mr. Jarman, which seems deduced more from theory than actual practice.

As to the cost, controversy on this point is useless, as nothing could be stated with any degree of certainty until a prolonged trial of a number of cars has been made; but it is obvious to everyone that the figures quoted are simply ridiculous. Without doubt there is a difference between Mr. Jarman's car and the Stratford electric locomotives, but in my opinion this was the most successful attempt at electric traction by means of accumulators that has taken place. They did run satisfactorily, though the cost of maintaining them ultimately proved, as many people had foreseen, quite prohibitory, and the consumption of plates must have been enormous. A similar "system" to Mr. Jarman's was tried on the Brighton and Shoreham tramways, and those who witnessed the miserable exploits of these accumulator cars must have learnt a lesson they will not be likely soon to forget.

With what bluster each so-called new accumulator car system makes a start, but who, beyond those who take the trouble to find out, ever know its ultimate destination? Like the proverbial month of March, the accumulator cars at Stratford came in with the roar of a lion, but they passed from the public view with the meekness of a lamb.

The continued building of accumulator cars with a mere rearrangement of parts will not further electric traction. Anyone worthy of the name of an electrical engineer can put accumulators and motor into a car, the thing is to get an accumulator that will stand the jar and heavy strain thrown on to it by tramway work, and from this it would seem that electric traction by means of accumulators is a problem more for the chemist than the electrical engineer. Yours, &c., F. C. ALLSOP.

MUNRO AND JAMIESON'S POCKET BOOK OF ELECTRICAL RULES AND TABLES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR, In your favourable review of this Electrical Engineering Pocket Book (fifth edition) in the *Electrical Engineer* of June 1st, at page 515, you remark, "Magnetic permeability, again, does not find a place, or we have failed to find it." If you will please turn to pages 434 and 435, you will find that both magnetic permeability and susceptibility have received attention, but that we have omitted any precise reference to these terms in the otherwise very full and complete index. This omission will be made good in the next edition.

Since the science of magnetism and electricity in its practical applications are advancing at such a very rapid rate, we are often at a loss to know what new facts should receive a place, and what older ones should be cut out. We are, therefore, very much obliged to you and to other reviewers for any useful hints to guide us in our earnest endeavours to keep the Pocket Book abreast of the times. If every one of your numerous readers who use the Pocket-Book would kindly jot down in the blank leaves placed at the beginning of the same their ideas upon any particular parts or points with which they may be familiar, or note any new experimental and useful data, and send them on to us through the publishers, or communicate them to your journal, we should feel much indebted to them, and should have much pleasure in thanking them in the next preface. The more critical, severe, and exact our contributors are, the better for the book, and the better we like them. —Yours, &c.,

ANDREW JAMIESON,
Professor of Engineering.

The Glasgow and West of Scotland Technical College,
Glasgow, June 5, 1888.

THE CAFE MONICO.

The Café Monico, Regent-street, which until recently contented itself with the large Siemens' gas lights for its saloons, has now been fitted throughout with the electric light, and considerable taste and care has been exercised in getting the best lighting effect with the most decorative arrangement of the fittings. The marble staircase and the marble entrance saloon, named by Messrs. Monico the Winter Garden, has eight electroliers of ten lamps (16 c.p.) each, of the design which we illustrate herewith, specially designed and made for the Café Monico by Messrs. Faraday and Son, of Berners-street. These are of chased and gilt brass work, with moulded glass globes, studded with ruby dots, and have a very handsome appearance. In the large Renaissance Saloon, lamps of a higher candle power are used, in a long single pendant of the design shown, but with long oval moulded glass globes, to match the electroliers. The lamps in these are 200 candle power. One of the pendants is suspended from each of the six arches of the saloon, visible outside for some considerable distance, and comparable in light, though not in colour, with neighbouring arc lights, are two large incandescent lamps of 500 candle-power, bare, with small opal shades above them. In the lower saloon are beaten copper and brass electroliers by Messrs. Laing, Wharton and Down. The kitchens and offices are fitted with the ordinary opal shades. The wiring was carried out by Mr. Merry. Machinery for supplying these lamps is situated in the basement, and was supplied and installed by Mr. W. O. Rooper, of Stafford. It consists of a 20-h.p. nominal engine with locomotive boiler made by W. G. Bagnall, of Stafford, which also supplies the

steam for cooking, a Phoenix dynamo by Paterson and Cooper, giving up to 360 amperes at 100 volts; a Blackman

air-propeller, driven off the dynamo shaft, expels the heated air. Provision is made on the switch-board for a spare

dynamo, and another engine and boiler will probably soon be erected to supply a further number of lamps.

CONVERTERS IN AMERICA.*

BY PROF. FORBES.

Having been asked by the Society to add some further account of the manner of working converters in America, I will now briefly comply with that request.

Engines and Dynamos. It is a mistake to suppose that one or two large engines are more economical than a number of small ones. A large engine working far below its power is very wasteful of steam.

One engine drives one dynamo by belt direct, without countershafting. It is well to have each unit in a station of the same size, so that parts are interchangeable and the attendant has less to think of. The size of unit may be chosen so as to supply, at efficient load, the minimum current required in the 24 hours. One exciter is generally used for four machines in series, with an adjustable resistance. A shunt resistance, largely made up of lamps, may be put on each field for regulation.

Feeders. These are generally overhead. Waring cable underground (lead covered) is perfectly successful. Simplex wire is generally used for overhead work. Five or six feeders are often fed by one dynamo. A loss of 2 to 2½ per cent. of potential is generally adopted. Double-bell insulators are used.

Converters.—These are made for 5, 10, 20, 30, and 40 lights. The wiring of a large house is best done with separate circuits for each 40 lights. It is unadvisable to "bank," or group in parallel a number of converters. These converters are very light, and have a smaller quantity of iron than might be thought good. They reduce the potential from 1,000 to 50 volts. The primary and secondary fuses are put inside the converter. The mode of manufacture of these has been described elsewhere. The insulation between the primary and secondary coils is indestructible.

Lamps. It is found that 50 volt lamps last longer than those with thinner filaments, and are generally used. The potential in the primary is 1,000 volts. No man has ever been killed by a 1,000-volt alternating current. It is well here to mention that you cannot get an arc from the low-potential circuit when an alternating current is used.

Meters.—The Westinghouse Company has made such arrangements as will enable them to charge customers by means of the coulomb-meter.

Station Ampere-Meters.—The same instrument as Edison uses is adopted, but with a bundle of wires sucked into the coil. Both the bundle and the coil form part of an arc of a circle, and the former moves on an axis at the centre of the circle. The force of the current acts against the weight of a counterpoise, and an index indicates the amperes.

Station Voltmeter.—A "three-point converter" reduces the potential either tenfold or twentyfold. A compound-wound "compensator" reduces the measured potential to that at the centre of consumption. The voltmeter is solenoidal in action, and is true only when the speed of engine is quite constant. The wire bundles for these solenoids are ingeniously constructed. A metal cylinder is covered with varnished paper or muslin. Iron wire is wound round the cylinder, sticking to the varnish. The iron wire ring thus formed is cut through and a flat web of iron wire is produced, which can be cut into lengths and rolled into bundles.

Ground-Detector.—Two converters have a lamp on each secondary. The primaries are connected in series to the mains. The intermediate contact is connected to earth. If one of the mains has an earth its lamp goes out. A multiple switch is provided by which each circuit can be tested in turn.

Synchroniser.—To synchronise any two dynamos, secondary wires are led to a switch-board. A wire from one converter is connected to a wire from the other. The two other wires are connected through two lamps. If the connected wires are in the same phase, the lamps go out. A switch is provided by which, as soon as the lamp goes out, the second dynamo is connected to the mains of the first. The dynamos work well in parallel

* Postscript to the "Discussion on Central Station Lighting," from the *Journal of the Society of Telegraph Engineers and Electricians*.

from half to full load. Alleghany station sometimes calls to Pittsburgh, across the river, for assistance in current, and the synchronism is good. Synchronism is found to be quite satisfactory from half to full load, but not below.

Switch Boards. A switch board is generally set up for each dynamo, and for five or six feeders. The conductors going to feeders run up and down; those going to dynamos are horizontal. The dynamo wires are connected with three instruments in a vertical row—an ampere-meter, a converter, and a voltmeter. Each feeder has a vertical row of instruments, a three-point converter, a compensator, and a voltmeter. There are six switches for six feeders in a horizontal row, to switch any feeder into either of two pairs of dynamo conductors. One of these pairs is connected to the switch-board dynamo; the other can be connected, by means of a switch at the side of the board, to the conductors of either of the neighbouring dynamos. An adjustable resistance, with six lamps in series for additional resistance, is at the bottom and middle of the board, and acts as a shunt on the field magnets. Another adjustable resistance is in series with all the field magnets. Another switch connects either of two exciters with the field magnets.

There are some other devices connected with street-lighting and theatre-lighting which I am not at liberty to describe, owing to the English patents being not yet completed.

AN ELECTRIC PUMP.

In large mansions where no water pressure is available hand-pumps are often used to pump the water to a cistern

supply stopping when the float rises, and continuing as long as there is insufficient water in the tank. It is therefore perfectly automatic, and the parts are so few and simple that it is not likely to get out of order, the wear is so slight that it will last for many years; and one further advantage is, that a much smaller cistern can be used than where the engine is only at work for a certain period of the day. The use of such a pump will no doubt extend at once where electricity is available, either from a central station or from a private installation, and, as the distribution of electricity proceeds, we shall no doubt find the electric pump filling an important place in the field to which electricity can be put. The Hollenden House Hotel, New York, has one of these pumps fitted to supply its two upper storeys, and it is working with great satisfaction. The No. 1 size pump has a capacity of 150 gallons per hour, with 25ft. suction, to raise water 50ft. above itself. It is driven from the connection with an incandescent lamp-socket, taking one-eighth of a horse-power.

POSSIBILITIES AND LIMITATIONS OF CHEMICAL GENERATORS OF ELECTRICITY.*

BY FRANCIS B. CROCKER.

Electro-chemistry seems less generally and less clearly understood than any other branch of electricity of equal importance. The facts concerning the dynamo, motor, telegraph, and telephone are widely and definitely known; but there are ideas, statements, and claims in regard to batteries which are further from the truth, more prevalent, and go longer without being contradicted, than any other collection of errors that I can call to mind.

New Electric Pump.

high enough to supply the upper storeys. In many cases steam or gas engines are employed, but for these a considerable amount of care and supervision is required in pumping. In town residences, hotels, and flats of great height, where the town pressure is not sufficient, additional pumps are often required. We illustrate a new pump for this purpose actuated by an electric motor, invented by A. E. Hall, of Plainfield, New Jersey, U.S. The machine is very neat and compact, and has a great advantage where a source of electricity is available, that no attention is required to be given to it, except an occasional oiling of the cups. It occupies about 24 square inches of space, and is practically silent in its operation. The wires are led to a float in the cistern at the top of the house, which plays the part of regulator and attendant; the

Primary batteries have not received the attention in this country that they have abroad, particularly in England, where the successful or unsuccessful attempt to float a new primary battery company is a matter of almost weekly occurrence. Nevertheless the subject is a sufficiently important one, and the false ideas of which I have spoken have spread so far beyond the quacks, to whom such ideas are usually confined, that the subject deserves more study than it usually receives, particularly from the scientific standpoint.

Electromotive Force.—The electromotive force which a given battery or combination of materials will develop is the first and most important question in electro-chemistry. Of course, the best and surest way to arrive at this E.M.F.

*Read before the American Institute of Electrical Engineers, May 16.

is to determine it by actual experiment with a voltmeter, or, still better, by comparison with a standard cell. There are, however, many times when the materials or instruments are not at hand, and a calculation or predetermination of the E.M.F. is very convenient.

The formula for calculating the E.M.F. is obtained by assuming that the electrical energy of the given chemical combination is equal to the heat energy which the same combination is capable of producing, or $EC = 4.16 C a H$. That is, volts multiplied by coulombs is equal to the coulombs multiplied by the electrochemical equivalent, i.e., the weight of material required per coulomb and that by the heat produced by one gramme of the material. Cancelling the C in both members, we have $E = 4.16 a H$, in which E is the E.M.F. in volts, a is the electrochemical equivalent (grammes per coulomb), and H is the number of heat units (gramme-degrees Cent.) produced per gramme of material by the given chemical combination. The values of a and H are given for most materials in electrical and chemical books of reference, and the calculation is a very simple one. Nevertheless, this formula and the principle involved in it are not generally understood, and are very seldom used. The equation deduced above is that ordinarily given; but what I have found to be a more convenient form of it is obtained by assuming that $E = H$, giving a its value for hydrogen (0.0001035). Solving with respect to H , we have $H = 23,300$, which means that 23,300 is the number of heat units per equivalent corresponding to one volt, and all that is necessary to find the E.M.F. of any given chemical combination is to divide the number of heat units per equivalent (which is the form they are almost always given in) by 23,300, and the quotient is the E.M.F. in volts. For example, to obtain the E.M.F. which zinc and free chlorine will develop, divide 48,600 (which is the number of heat units produced by the combination of one equivalent of zinc with one of chlorine, as given by Thomson) by 23,300, and the result, 2.09, is certainly very close to 2.11, the actual value obtained by experiment. In the same way the E.M.F. of other combinations of materials may be predetermined, but it should always be borne in mind that the heat of combination corresponding to one equivalent of the material should be taken, and not necessarily that corresponding to one atom, as, for example, in the case of zinc, the heat per atom (65 grammes) is 97,200 which has to be divided by 2 to reduce it to one equivalent because zinc is a dyad, and takes two atoms of chlorine, which is a monad. In the case of monad metals like sodium, potassium, and silver the figures may be taken just as they given in the tables. Mistakes very frequently arise in this way, in fact, I do not think I ever saw a table of electrochemical equivalents in which this point was correctly introduced in every case.

In order to test the practicability and accuracy of calculating E.M.F., as well as to obtain reliable results and full data for their own value, I determined the E.M.F. given by thirteen of the most important metals in combination with free chlorine, bromine and iodine, and the results are given in Tables A, B, and C respectively. In Table D, I have averaged these results and placed them side by side with the results obtained by calculation. The agreement between the two sets of figures is not perfect by any means; but when it is remembered how the E.M.F. of a cell will change one or two-tenths of a volt on apparently the slightest provocation, I think the figures are strikingly close, more so than I expected to find them. In more than half of the cases the difference is less than one-tenth of a volt, and the average difference is only slightly more than that. There has been no warping or coaxing of the figures to secure uniformity. The results are given just as they came. If figures were picked out from the different observations, it would be possible to obtain almost perfect agreement between the calculated and determined, as one may see by looking over the tables.

In regard to the experimental results, as given in tables A, B, and C, I may state that all the metals and salts used were chemically pure, with the exception of the metals magnesium and aluminium, and these were of a very good quality. Pure carbon plates were used for the negative plate, but platinum was also tried and gave substantially

the same results. The E.M.F. was measured by a Thomson reflecting galvanometer (by Elliott), using two independent standard Daniell cells. One fact which strikes one in looking over the tables A, B, and C, is that the E.M.F. is not very greatly affected by the solution; a certain metal gives about the same result in one chloride as in another, and the same is true of the bromides and iodides. In Table E, I have given the E.M.F. obtained by substituting different metals for the zinc in a Daniell's cell, but these results being from only one series of observations are probably not so reliable as those in the preceding tables.

In the remaining table I have collected in condensed form the principal facts in regard to batteries in which zinc is used as the electro-positive material with the most important electro-negative or depolarising materials. The facts in regard to metallic zinc, which hold good in all cases in which it is used (no matter what the other material is), are given on a horizontal line with zinc. Below this, the facts in regard to each particular combination are given opposite the depolariser. For example, the data of a zinc and chlorine battery are given on a horizontal line with chlorine, of a zinc and nitric acid (Bunsen) battery, on a line with nitric acid.

For convenience the table is divided into two parts, the left hand side contains the purely scientific data, and the right hand portion contains the practical facts.

In the first column of the first part are given the chemical symbols reduced to a common basis, any one of the expressions being chemically equivalent to any other. For example, one half atom of zinc ($\frac{1}{2} \text{Zn}$) requires one atom of chlorine (Cl), or one half atom of oxygen ($\frac{1}{2} \text{O}$), or one third molecule of chromic acid ($\frac{1}{3} \text{Cr}_2\text{O}_3$), or one sixth of the mixture of one molecule of potassium bichromate and seven molecules of sulphuric acid ($\frac{1}{6} [\text{K}_2\text{Cr}_2\text{O}_7 + 7 \text{H}_2\text{SO}_4]$), and so on.

In the second column is given the chemical equivalents, which are simply the proportions by weight required of the different materials. That is, when we use 32.5 grammes (hydrogen being assumed as one gramme), we require 35.5 grammes of chlorine, or 33.4 grammes of chromic acid, and so on.

The third column contains the electro-chemical equivalents, which are really exactly the same and directly proportional to the combining weights in the previous column, but are reduced to an electric basis of so many milligrammes per coulomb. To convert these figures into grammes per ampere hour simply multiply by 36.

In the first column of the second part of the table is given the E.M.F. of each combination, all of which, with the exception of oxygen, sulphur, and water, are determined by experiment, most of them being well known and accepted values. In the case of oxygen, sulphur, and water, the E.M.F. is calculated as explained above, and are merely given for comparison. No actual battery corresponding to these materials exists.

In the second column on the right hand side is given the number of pounds of zinc required per h.p. hour in the case of each combination. For example, a zinc and copper sulphate (Daniell) battery requires 1.86 pounds of zinc per h.p. hour of electrical energy produced.

In the next column I give the weight of depolarizer required per h.p. hour in the case of each combination. For example, a battery requires 5.05 pounds of the mixture of three parts of potassium bichromate, and seven parts of sulphuric acid, which is about the ordinary strong bichromate solution for porous cell batteries. Of course the water required for the solution is not considered here, or in any of the other figures of the tables, because it costs nothing and serves merely as a medium of electrical action; but if the total weight of solution is desired, the weight of water must be added.

The weight of the different materials consumed per ampere hour is given in the next column. These figures are obtained directly from the electro-chemical equivalents in the third column by dividing by 1.25; in fact, they are simply the electrochemical equivalents in pounds per ampere-hour.

It should always be carefully noted that the weight consumed per ampere hour is that required in each cell in series, whereas in the case of horse-power hours the weight given

in the table is the total weight used, no matter how many cells there are or how they are arranged.

In the next to the last column is given the wholesale cost per pound of the different materials. These prices are of course very difficult to fix, because they depend upon the market and vary greatly upon the quantities bought; but the prices I have here are very low, and ordinary consumers would have to pay twice as much in most cases, they give, however, some idea of costs.

In the last column, I have given the cost of both materials, zinc and depolariser, added together. I have not here considered the values of the products, because it is very difficult to estimate the cost of collecting and utilising residues. In the case of silver chloride, the silver resulting from the action would, of course, be worth a large portion of the cost of the original chloride.

One of the interesting points which this table shows is the total weight required per horse power hour. For example, .95 pound of zinc and 1.04 pounds of chlorine, making a total of almost exactly 2 pounds, would produce 1 h.p. of current for one hour if all of the chemical energy could be converted into electric energy.

This brings up the question of how large a percentage of the chemical energy can be utilised, or, in other words, the efficiency of chemical generators. This efficiency is higher, I think, than it is generally supposed to be. I have no exact figures upon this point, but I have tested several times the weight of zinc consumed compared with the theoretical amount, and I have found that even in a plunge battery, where the bichromate solution was directly in contact with the zinc and the opportunity for local action was a maximum, that the zinc efficiency was as high as 75 per cent., and in one case 80 per cent. In a porous cell battery with amalgamated zinc, where there was little or no cause for local action, I believe the zinc efficiency would be as high as 90 per cent., and I should not be surprised to find it as high as 96 or 97 per cent.

The efficiency of the depolariser is generally lower than that of the zinc, because there is generally a good deal of chemical energy left in the solution after it is too weak for satisfactory work. The efficiency of the bichromate solution in the plunge battery I have just referred to was only about 45 per cent. of the total theoretical power. But this is very low, because the solution has to be weak in acid on account of being used in contact with the zinc. In the case of a copper sulphate battery, where the crystals of sulphate are often almost entirely used up, I think the efficiency would be as high as 80 or 90 per cent.

The efficiency I speak of here is simply the chemical efficiency in the battery; the fall of potential in the battery due to its internal resistance compared to the external is another loss which has to be added to the chemical loss in determining the total efficiency. The possibilities of chemical generators are therefore almost infinite, since it requires theoretically a total of only two pounds of zinc and chlorine, and two pounds of zinc and chromic acid per horse power hour, and since the efficiency of batteries can easily be made as high as 75 per cent., it follows that less than three pounds of material is actually required per horse power hour; but unfortunately the water for the solution, the containing vessel, electrodes, &c., are so heavy that the total weight is very many times greater. The possible and the actual battery are thus very far apart. If we use metals of higher chemical affinity and E.M.F. than zinc, the theoretical weight of material required is even less; only one pound total of chlorine and magnesium are required per horse power hour, with metallic sodium and free chlorine having a calculated E.M.F. of 4 volts it would only take about .8 pound per horse power.

The easiest and best solution of the problem, however, does not seem to be the use of more powerful metals than zinc. The latter is powerful enough; it only takes, as we have seen, about one pound of it per h.p. hour with nitric acid, chromic acid or bichromate solution, and less than two pounds with copper sulphate. The opportunity for improvement seems to be more in the direction of perfecting the general form of batteries. The apparatus is at fault, not the chemical action. Moreover, zinc is about as high on the electro-positive scale as it is safe to go, so long

* Calculated.

as water is present. Even in the case of zinc, its affinity for oxygen is greater than that of hydrogen; it is therefore only by tolerance, so to speak, that zinc remains passive in the presence of water. If it is not properly amalgamated, or if the solution is too strong, local action does occur. If in place of zinc we use any more electro-positive metal, these troubles are aggravated. With magnesium, for example, there are only very few solutions in which it will stand without great local action. Metals of still higher power, such as sodium, cannot be used at all in the presence of water. Jahlochkoff has, I believe, made cells in which sodium is used with damp cloth, but this can hardly be considered as water.

The proper way to use metals of great chemical energy would seem to be with liquids which do not contain any oxygen, but unfortunately such solutions are not generally good conductors. Another possible plan is to employ a fused electrolyte, but this involves the serious difficulty of maintaining it in the fused state.

So far as I can see, zinc is a very satisfactory positive material for batteries. After all, it is cheaper than any other metal except iron. It is a sufficiently good conductor and less dirty and liable to corrosion than almost any other metal; it is also, as I have just shown, about as high on the electro-positive list as it safe to go.

The electro-negative materials, on the other hand, leave far more to be desired. They are generally very expensive, very troublesome to handle, and introduce that quality of simple dirtiness, to which no other name can be applied, and which is really the most serious objection to batteries. The electro-negatives will, however, do the work, and as we have seen it actually requires very little weight to give a great deal of power, if the materials could only be used in a more perfect manner than at present. That seems to be the thing to hope for. Another serious difficulty with batteries is their high internal resistance. A dynamo can easily be made to give 100 volts with a thousandth or a few ten thousandths of an ohm internal resistance, hence their great output; but a battery capable of giving 100 volts with only one thousandth of an ohm internal resistance would probably fill this house.

In this connection it will be interesting to consider how many cells of ordinary gravity battery are required to give one horse-power of current. Each cell will give one volt, and not more than half an ampere under normal conditions; hence each cell furnishes half a watt, or about 1,500 cells to the horse-power! These cells would, however, give that power for a long time; but the fact remains

that that very large number is required to produce the power which a dynamo not much larger than one's hat will generate.

In conclusion, I would say that I am by no means a sceptic in regard to chemical generators of electricity. The possibilities are very, very great, as I have shown; but these possibilities do not seem to have been brought to reality in a very perfect manner as yet. But batteries, even in the imperfect state in which they exist to day, have their useful and legitimate function. A Leclanché cell is exceedingly well adapted to ringing electric bells intermittently and to telephone work, and gravity batteries have long done good service for telegraphic purposes.

But when it comes to developing any considerable amount of actual power, then the limitations become apparent. When we remember that battery electricity will certainly cost in practice 50 cents per horse-power hour, since the materials alone cost 25 cents, and that dynamo electricity only costs two cents per horse-power hour, the claims of some primary battery electric lighting promoters show up in their true light. As a luxury, of course, it makes very little difference what it costs, but even then people soon tire of paying very high prices for that kind of a luxury. For small electric lighting, and small power in special cases, batteries are useful, particularly where no other source of current is available. A physician or dentist, to whom a horse-power hour may be worth hundreds of dollars, could almost afford to use a chloride of silver battery and throw away the silver.

A Simple Electroscope.—In examining the dry film of collodion, Prof. Jouravski has found that it can be electrified negatively with great facility. It is sufficient to rub it slightly between the fingers. As it is extremely thin, it will approach objects electrified positively, and repelled from those negatively electrified. In this way, with a strip of collodion film, the polarity of electrified objects can be readily verified. To prepare the film the collodion is poured on a glass of water, and after the ether is evaporated the film which remains can be easily removed and cut into long, straight strips, each of which constitutes a perfect electroscope. These bands should be kept in an obscure place. The author mentions these facts with the idea that such a simple and ready electroscope may be very useful to physicists.—*Russian Physico-Chemical Journal*.

PHYSICAL SOCIETY—May 26.

MR. SHELFORD BIDWELL, F.R.S., Vice-President, in the chair.

Mr. S. O. Roberts was elected a member of the Society.
The following communications were read:—

"Note on the Governing of Electromotors," by Prof. W. E. Ayrton and J. Perry. In a paper read before the Society of Telegraph Engineers, in 1882, the authors defined the conditions of self-regulation of electromotors for varying load when supplied either at constant potential or with constant current. The conditions involved "differential winding," i.e., the use of a shunt motor with series demagnetising coils. With this arrangement fairly good regulation has been obtained, but owing to want of economy the methods have not been developed further. Since then another arrangement, in which a simple shunt motor is used and a few accumulators placed in series with the armature, has been devised for working on a constant current system. By means of a suitable switch the accumulators can be charged when the motor is at rest. On the assumption that the E.M.F. of materials given by $E = a(p + tZ)$ where a = speed, Z = number of turns on magnets and p and t are constants, it is shown that the speed at which a motor will govern is given by $\frac{C}{a + a^2}$, and the constant current $C = \frac{a + a^2}{a}$.

where a and a^2 are the resistances of the shunt and armature respectively, and C and a^2 the E.M.F. and resistance of the accumulators. Since a and a^2 may be small and a^2 not large, the value of C need not be great to give a considerable value for C , and thus only a small number of accumulators will be required.

"On the formulae of Bernoulli and Haeker for the Lifting-power of Magnets," by Prof. S. P. Thompson, D.Sc., read by Prof. Perry. The formulae referred to are $P \propto \frac{1}{W^2}$ and $P \propto \frac{1}{W^2}$ respectively, where P = lifting power, W = mass of magnet, and a a constant depending on the material and shape of the magnet. These formulae, the author shows, are equivalent to saying that the lifting power of magnets in which the magnetic induction B has been carried to an equal degree, is proportional to the polar surface, and that Haeker's coefficient a is proportional to B^2 through the surface. Assuming the induction

uniform over the surface, it is shown that $P = \frac{1}{8\pi} B^2 A$, where A = area of surface, and this gives a very convenient method of determining B from measurements made upon the pull exerted at a given polar surface. If P be measured in kilos, and A in square cms., the formula for B becomes $B = 5,000 \sqrt{\frac{P}{A}}$, and if the

measurements be made in pounds and inches the constant becomes 1,317. It will be readily seen that the greater power of small magnets in proportion to weight does not require for its explanation the sometimes alleged fact that small pieces of steel can be more highly magnetised than large ones, for if B be the same the lifting power will be proportional to the polar surface, and not to weight and hence must necessarily be greater relatively to weight in small magnets. In the case of electromagnets for inductions between 6,000 and 16,000, between which the permeability, μ , is approximately given by $\mu = \frac{16,000}{B}$

the lifting power is shown to be $P = A \left(\frac{3.2 S i}{S i + 2.56 l} \right)^2$ Where P is in kilos, A in square centimetres, S = ampere turns and l = mean length of the magnetic circuit.

"Experiments on Electrolysis." Part II. Irreversible Conduction. by Mr. W. W. Hubbard, B.Sc., and Mr. H. Holden, B.Sc. An abstract was read by the Secretary. The authors have observed when strong sulphuric acid is used as an electrolyte, the electrodes being of platinum that the decomposition nearly ceases if, by decreasing the resistance in circuit it is attempted to increase the current beyond a certain maximum. When this condition called the insulating condition is arrived at, reversing the current immediately restores the conductivity. Experiment shows that the current density is an important factor, and that the composition, viscosity, and temperature of the electrolyte, as well as the previous history of the electrodes have considerable influence on the current density at which the insulating condition occurs. The seat of the insulating layer is found to be at the anode, and the authors believe it due to very concentrated acid formed around the electrode, whose specific resistance is very high. Experiments were also made with carbon and gold electrodes, and phosphoric acid, caustic potash, soap, and sodium benzoate were used as electrolytes, the result of which seem compatible with the concentration hypothesis above stated. The paper contains an historical and critical account of allied phenomena, and tables expressing the numerical results obtained by the authors are given.

THE ELECTRIC LIGHTING MOVEMENT IN BRADFORD.

LOCAL GOVERNMENT INQUIRY.

On Thursday, May 31st, Major Tulloch, R.E., one of the inspectors of the Local Government Board, held an inquiry at the Town Hall, Bradford, in respect to the application of the Corporation for sanction to borrow £20,000 for the purpose of the proposed electric lighting installation in the borough. There were only about half a dozen

* Irreversible conduction is said to occur if a reversal of the direction of a current causes any change in its magnitude.

persons present in addition to the inspector. Alderman Frederick Priestman, chairman of the Gas Committee, and the Town Clerk Mr. McEwen, represented the Corporation; and Mr. J. N. Shoobred, electrical engineer to the Corporation, was also present.

The Town Clerk, in laying the case of the Corporation before the inspector, stated that some time since the Corporation obtained a confirmatory Act of Parliament which empowered them to supply electricity for lighting purposes and for motive power. By that Act two years' grace was given to the Corporation, within which time they were to do something towards putting into operation the powers granted, subject to the condition that if the Corporation did not move within that period, and any company wished to take up the project, the powers granted to the Corporation should not stand in the way. Before the two years expired, however, the Corporation introduced a Bill into Parliament containing clauses seeking to make their electric lighting powers permanent. The Board of Trade, after considering that portion of the Bill, came to the conclusion that it would be undesirable to give to the Corporation such powers in a permanent form, but gave them an assurance that if any other person came to the borough with any project the Corporation should be duly considered, and the powers granted to them should remain in their hands unless there had been unreasonable and wilful default on their part. About that time, as the inspector would be aware, the subject of electric lighting was not so far advanced as it had since become, and it was thought best to let the matter remain in abeyance for awhile, pending such improvements as might be made. Some time afterwards a company came to the Corporation and asked for permission to carry cables over the streets. This seemed to the Corporation a most objectionable mode of procedure, considering the weight of the cables and consequent danger to the public; and as other persons, including the Post Office authorities, were required to carry wires underground in the busy parts of the town, the Corporation refused the application. To some people it might have seemed ungracious on the part of the Corporation to refuse liberty to the company to use their electric powers, while at the same time the Corporation had similar powers but neglected to carry them into effect. The Gas Committee thought it well to bring the subject up for discussion in the Council, and, it being found that there was likely to be a considerable demand for the electric light, it was, after full inquiry and consideration of the subject in all its bearings, determined that the Corporation should make a start. No one, however, yet knew sufficient of electric lighting to justify the setting up of a complete system for the whole borough, and it was thought that the most judicious mode of proceeding would be for the Corporation to select a central portion of the town and to have a limited installation put down until it was seen how far the project was successful. Plans were therefore prepared by Mr. Shoobred, acting for the Corporation, and it was resolved to seek powers to borrow the necessary money, and the Council having made application to the Local Government Board for that purpose, as directed by the Act of 1883, the result was the inquiry now being held. As the inspector well knew, the Corporation was required to give the utmost publicity to everything they did, and such had been the case in the present instance. So far as could be ascertained, the scheme seemed to meet with very general approval, and the absence of opposition was a strong testimony in favour of this view. It should be stated that the trade of the town was of a peculiar character, and the Corporation were told by the merchants that the electric light would be a great convenience to them, as facilitating the matching of tissues of the various textile fabrics produced in the town, as also in showing off the various shades of colour. It remained for the inspector to say whether he felt justified in recommending that sanction be given for the Corporation to borrow the amount for which application had been made. It was at first thought that £20,000 would be sufficient to meet the demands, but when tenders had been received for the necessary works, it was found that nearly the whole of that sum would be absorbed, and the Corporation requested to be allowed to amend their application so as to include an additional £5,000. In the year 1871 the Corporation bought up the undertaking of an old gas company, and it might perhaps be thought that in seeking now to supply electricity they were cutting their own throats; but being satisfied that there was a demand for the electric light, they wished to be able to supply it themselves, and so maintain the exclusive control of the streets, as they were apprehensive that if any trading company were to get a foothold in the town the difficulties of the Corporation would be very much enhanced. It was most desirable that only one authority should deal with the streets, and every arrangement would be made to secure economy in carrying out the project.

Alderman F. Priestman added his confirmation to the Town Clerk's statement, and explained the desirability of having the works proceeded with as soon as practicable. Considering the substantial character of the plant to be laid down, he urged that the term of the loan should be as long as possible.

The Town Clerk proposed to call Mr. Shoobred the Corporation's electrical engineer; but the Inspector stated that the engineer had already supplied him with the fullest particulars, and that no further information was really needed on his part, adding that there was nothing in relation to the scheme generally, or arising out of the inquiry to which he saw the least objection. The Inspector remarked that the best course for the Corporation to adopt would be to submit to the Local Government Board a supplementary application for the additional £5,000 required. It was highly desirable that an inquiry should have been held, as the subject was new both to the Corporation and the Department. Indeed, he believed the Bradford Corporation were the first municipal authority to take action in the manner they proposed.

On the motion of Alderman Priestman, seconded by Mr. Joseph Edmondson a vote of thanks was passed to the inspector for his courtesy in conducting the inquiry, and Major Tulloch having responded, the proceedings closed.

COMPANIES' MEETINGS.

SWAN UNITED ELECTRIC LIGHT COMPANY.

An extraordinary general meeting of the Swan United Electric Light Company, Limited, was held on Tuesday at the Cannon-street Hotel, for the purpose of considering and, if deemed desirable, approving of an agreement dated May 5, 1888, and made between the Company of the one part and the Compagnie Continentale Edison de Paris of the other part, and of authorizing the Directors to do all acts necessary for carrying such agreement into effect. Mr. James Stuart Forbes occupied the chair.

The Chairman. Gentlemen, this is a very important meeting for the shareholders of this Company. I will try to be as brief as possible, but in view of the great importance and perplexity of the matter I am afraid I shall not be very short, because I think it necessary you should understand what you are about to do. What we are about to do is, in fact, to imitate abroad what we have done with great advantage to ourselves at home. You know the history of the United Company, in which you have a very large interest, you were in litigation with the Edison Company as to the respective patents of Mr. Swan and Mr. Edison in Great Britain and Ireland. We took very strong views of the priority and value of the Swan patents. They took the same views as to priority and value of the Edison patents, and we were fast verging upon what might possibly have been run to both companies—litigation to the death—to settle which was the governing patent, and whether there was any patent at all. In that state of things, happily for us, prudent counsels prevailed. The two companies were put together on the theory of making the best of what had been done, assuming bona fides on both sides, in building up the united business, which should have the advantage of preventing litigation, the raising of very delicate questions as to the value of priority of both sets of patents, by uniting them both for the purpose of defence against the common enemy, the infringer. Now, that is what we did in England; it was rather more easy here for the reason that the Edison Company had got the entire control of the Edison patents in Great Britain and the Swan Company had got the entire control of the Swan patents. There were no other interests. But abroad it is a little different. There, as here, Mr. Swan and Mr. Edison are face to face, as here, the one accuses the other of infringement. The Swan Company abroad are in the same position as they were here—that is to say, wherever patents have been registered they are the sole possessors. That is not quite the case with the Edison, they seem to have been handed over originally to one or more parties by Mr. Edison, and as we have to deal with things as we find them, it is not much good going into their history. We find, however, that the Edison Company, of Paris, with whom we are dealing, has not the same absolute power over the patents for the whole of Europe that the Swan Company has, or that the Edison Company had in Great Britain. You will see at once that led to rather more difficulty in negotiation. There have been more "Richmonds in the field." The Swan Company for the last two years has been not indisposed, in view of legal proceedings on patents, to come to an agreement with the Edison Company abroad. But we were face to face with considerable internal difficulties—in fact, to know who we were to negotiate with, and how one district was to be protected in which one set of people had the command, and another in which another set of people had the command. That has taken a great deal of time, and we have come to the conviction that it was wise to do abroad what it was wise to do here, for the very same reasons. While conflicts were going on, there was great uncertainty and cost in fighting. In the second place, the fact of there being litigation has a depressing effect on the spread of the invention. People do not like to go into installations and run risks of being served with notices from time to time that they may be preparing for themselves the defence of an infringement suit; the object, therefore, was to put these companies together. The object and the reasons were generally what I have stated for the purpose of mutual protection, advantage, and defence, because in every place in Europe there are lots of clever fellows who will make and sell lamps on the patent of Mr. Edison and Mr. Swan and pocket the benefits if we let them. Now we shall be much stronger and united against infringers by having both sets of patents under our control; and besides, in a place in which one patent may be weak in another it may be strong. We then come to the delicate point to all such negotiations, the relative value. It is very difficult to find out and appreciate the relative value of what is partially unknown, because, although we have heard of the Swan and Edison lamps for a good many years, the business is still, so to speak, in its infancy. It is a great undeveloped business, and the development of that business would depend very much, if we remained distinct companies, upon who won the suits. If the result of that litigation was to bar the Swan Company from manufacturing lamps all over Europe, and to give the Edison Company, so to speak, the monopoly of that manufacture, the relative portions or values would be greatly altered. Those questions have never been brought to issue. We have had to resort to the only known factor which influences men's minds in the circumstances, that is, having both gone on the theory that the patents were valid patents. We have each done a business, we have each a going concern. The businesses have been founded on different principles. We, for instance, have paid cash for our patents, the other people have bound themselves to pay royalties on their patents. We have spent a great deal of money in these foreign countries bringing our business to its present standard of expansion—well, we have gone on the simple factor, how much work had we done, how many lamps had we manufactured and sold. That seemed to be one reasonable factor. That had to be modified by some considerations. For instance, if these suits which are pending in different countries—in Germany, in France, in Austria, and in Belgium—if they should go absolutely against one company or

the other, that would be a very disturbing factor, or if the result was to throw these patents open to all the world, we should both be in a bad state. Many people would hesitate to attack a united company, but no one would, if the result of the action of the two companies was to proclaim to the world that the patents were not binding and were open to all. We have taken similar views on both sides of the relative value of that factor. Fortunately, the method of computing the proportions does not involve the necessity of dealing with the capital of either company, in going into the question of what it has cost "A" or "B" we have taken the factor of the business actually done as the basis of the future division of the profits of the business. The thing was to get rid of this litigation, and to proceed as a united company to extend the business. The administration costs will probably be somewhat diminished. The efficiency of the lamp will be greatly improved, the public mind will be set at rest, there will be no alarming forebodings that people may be charged as infringers and subject to legal proceedings. The business will increase, with the increase of numbers the profits on lamps will greatly increase. This is one of those businesses where a comparatively small number of lamps means a profit inconsiderable in comparison with a much larger output. The charges are comparatively great on the small quantities, and are greatly diminished on the increased output. Supposing, on an output of a quarter of a million, you make a shilling a lamp, if you increase the output to half a million, the profit may be 1s. 6d. What we think is, that our plan of putting these conditions together will effect a laudable object—not only increase the output, but it will reduce the cost of each individual lamp, so that the profit will be greater.

In order to express in legal language what I have told you in so few words, it has been necessary to enter into an agreement with this continental company of Paris, and I had better perhaps briefly, before submitting the agreement to you for your information, go through the different articles, so that you can understand exactly what it is. It is to be a union of the two companies, and is to be called the Company General of Incandescent Lamps. The duration of the Company is to be fixed by the statutes up to December 31, 1894, that being in fact about the day, or a little beyond the day, when the patents of both Edison and Swan lamps die. It is a few weeks in case of the necessity of winding up the companies. In that event there would be time to do it; but that term may be prolonged or reduced, if the necessity should arise, by the resolution of a special meeting called for the purpose, but only when such resolution is passed by a majority of three-fourths of the share capital of the Company. I cannot myself see any reason to believe that, during the term of the patents at all events, there will be any necessity to interfere with this as a going concern. I think it is exceedingly likely that if the business is managed with tolerable prudence that at the end of the six years you will have a well established going concern not protected by patents—which will then be open to all the world—but probably protected by improved processes which in the interval may be patented; at all events, if not that, by a large connection all over Europe and by a trademark which I hope will have behind it the character of the most efficient and best incandescent lamp which can then be produced. If that be so, this Company would go on. It would go on, I suppose on conditions which we need not even anticipate now, but I should think possibly very much on the conditions of this agreement. I must tell you that this is to be a French company—that is to say, a société anonyme, which is equivalent to our limited liability. The seat of the Company will be in Paris, but may be transferred to any other place. What do the parties bring in? This is an arrangement based on bringing in a going concern, or rather two going concerns; we propose to bring in what we have got, and they propose to bring in what they have got. What they would bring in is France, Belgium, Austria, Hungary, and Spain. That is where the Edison patents are under the control of this Company. We bring in France, Belgium, Russia, Austria, Hungary, Italy, Sweden, Norway, and Portugal. There is one important area entirely left out—that is Germany. The gentlemen in Paris have not the power of controlling the Edison interest in Germany, and, as I have had occasion to tell you at some of our meetings, in Germany, amongst other places, we are in litigation. But it is not impossible, when this preliminary step has been taken, Germany may follow. However, Germany is excluded from this agreement, the reason being that they cannot bring in Germany. There is one point of importance which I should be very glad to make clear. I said that this business had been founded on different principles; whereas we out and out bought the Swan patents by shares and money, the foreign people submitted themselves to a tax, or license, or royalty. I think, is the proper term, of 20 centimes a lamp. This has been one of our great bones of contention and difficulties, these 20 centimes. Well, it is the payment made to Mr. Edison for bringing in his brains and patents. In France he got a royalty of somewhat under 2d. on all the lamps manufactured within the area of these patents. We have had to look at that, amongst other things, and we have seen fit. I do not know that I need enter too largely into the discussion of why, as a matter of prudence, and after full consideration—to accept that 20 centimes as a charge on the old business, but only for the duration of the patents. Now, that is one of the points which made us insist so strongly upon each party bearing its own burden. The contract was that 20 centimes should be paid as long as the Company existed. We have agreed that it shall be paid till the end of the patents. I have told you what everybody brings in, and the consideration for bringing it in is the creation of a certain quantity of shares representing what has been done heretofore—what I may call the cost of the affair up to date—and a further amount of shares representing the capital which it will be necessary to find to develop this business from time to time. Now, it is not a big thing; you need not be alarmed by supposing you have immediately to find more capital. The share capital of the Company is to be 2,000,000*fr.*, which is £80,000 of which 1,000,000*fr.* is to represent in fully paid shares the values of the going concern as put into the common pot, and the other

1,000,000*fr.* is to be made up of cash contributed by the Companies in the respective proportions in which the profits of the united concern are to be divided. The division of these profits was a very anxious matter, and I think you may give us credit for having been ourselves largely interested—not that I think the mere pocket influence is the full consideration which ought to find honorable men acting in the interest of others, but still it has a certain interest. But being, first of all, large shareholders, and, what is more, being the respectably-trusted directors of this Company, we made the hardest possible fight about the proportion; and I think Mr. Leyland, who has taken an immense deal of pains over this matter, will agree with me that we have reason to be very well satisfied with the proportions brought out. We think that looking at the relative work done by the two Companies, looking at the risks of litigation in these different countries, looking at the position which these people have got into in France, Belgium, and Austria by combinations which they have made with important people that they stood upon the very nature of the thing to do a bigger business than we did, that is to say, that their chances, if we had gone on even in friendly way, were of a character to give them a better business than ours. Then there was the great risk of our falling on these patents, and that was a very serious matter so that altogether the Directors are quite satisfied, and have prepared to take the responsibility of recommending you to accept the proportions. I have told you what the respective proportions of the Companies are to be in consideration for their contributions. There shall be allotted to the Continental Company 1,200 shares, and to the Swan Company 800, of 50*fr.* each, fully paid up. That represents the million of francs which I told you would be represented in shares of the going concern. The other 2,000 shares are to be subscribed, 1,000,000*fr.* in cash in the same proportion as the above contributions, and we shall have to put £16,000 and these gentlemen will have to find the balance—£24,000—and the profits realised in the future will, of course, follow the shares. Of every £100 profit made they get 60 per cent., and we get 40 per cent., and we think, looking at the matter all round, it is a very satisfactory bargain, and the more one looks at it the more satisfied he becomes. By uniting these companies on these conditions we get rid of the litigation, and shall be able to build up a trade-mark and a business of great value by the time of the expiration of the patents. We think we have done very well indeed, looking at the outlay of the two companies, in arranging for that amount of the net profit, because, after all, the number of shares represents the concrete value, which works out at 60 per cent and 40 per cent, respectively. Under the arrangement the two Companies are put together as a going concern in these countries, and there is an end of all litigation—each party withdraws from the litigation and pays its own costs. One very important matter is this: Suppose in the interval there should arise some unforeseen—as far as the present goes—necessity for terminating this bargain, which could be done in general meeting, recommended by the Directors, each Company would return to the *status quo ante bellum*, or, perhaps I should say, *ante pacem*, with all its rights intact, but not with its right to litigate. Therefore if at the end of two or three years we should dissolve the partnership—which I cannot foresee—it has been provided for, it would not mean a revival of litigation. Neither party can challenge the rights of the other in the future, and that seems to be a matter of some value looking at the cost of this litigation. Then, there is the capital. We get 1,000,000*fr.* as representing what we put in in fully paid-up shares, and I may say in the presence of a couple of distinguished lawyers, one English and the other French, that the recent decision does not affect the rights of any company to do what we are doing—it represents so many thousands paid down to carry on the business. These are the general terms of the agreement, but there are some exceptional things I ought to call attention to.

The only charge resting on the business, over and above the cost to the parties, is that 20 per cent., and we, for reasons which are satisfactory to our minds, thought it better to accept that for the term of the patents. But there are some other conditions. We were pretty free all over Europe. We had not committed ourselves very much, they had. They had made bargains with a very important firm well known in this country—Sir William Siemens and Co., who are equally powerful people in Germany and elsewhere abroad. They were large manufacturers or installers of electricity abroad, and they had made contracts with the Edison Company under which, in Austria-Hungary and Russia, they are entitled to manufacture lamps, as lessees, upon the terms of certain royalties to the parent Company. We have had to face these different arrangements, and there is no getting rid of the bargain with Siemens, but what we have stipulated is that all benefits arising under that shall come into the common pot. Siemens pay 37½ centimes for the right to manufacture the lamps, and they manufacture on a considerable scale, though not so large as to interfere with the scope of our company. They may like to take our lamps at the trade price, or make lamps themselves and pay the royalty, and the parent company undertakes to hand these royalties over. They have similar arrangements with the Italian society and with a large firm in Belgium, and what ever the profits are they will come into our pot; they are not entitled to make any charge for doing the work, and we have the power of control to the extent of examining their books. We have reserved for our company the right to manufacture lamps in Germany and sell them as long as the law will allow us, and if anybody chooses to buy lamps in Hamburg or any of the German ports for export, not to Great Britain but to any parts of the world where there are no patent laws, we shall be free to do that business. This is the general character of the bargain, though, of course there are a great many details. The French Company have other business besides lamp-making, such as the manufacture of dynamos, but we shall not enter into these. The future, of course, involves articles of association and the appointment of the directors. Therefore it becomes a matter of confidence. We are very well satisfied with the outcome of the discus-

sion. Of course we go in as the minor factors, and we were careful to consider how that minor factor was to be protected from being over-ruled and outvoted by the major factor. What we did was to get three Directors out of a total of seven. That still leaves the governing power in the hands of our French friends, but we could not reasonably claim more. The Directors would be nominated for the whole term of the agreement, and it was for the shareholders to say whether they will run the risk of so nominating their Directors. The French company have nominated Messieurs Bernhart, Chatard, Rat and Verges, while your interests will be represented, if you approve of this agreement, by Mr. Leyland, Mr. Simon—our agent in Paris since the formation of the company, a man of exceptional intelligence and straight-forwardness—and myself. Article 12 decides what is to be done with the net proceeds, after deducting the working expenses. There is to be a reserve fund of 5 per cent., which is according to the common law of France; 6 per cent interest on the shares; then from the balance shall be set apart 10 per cent for the Board of Directors, to be distributed amongst the members in equal parts. Thus, if the shareholders do not get 6 per cent the Directors will get nothing. I beg now to move. "That the agreement now submitted, dated May 5, 1888, and made between the Swan United Electric Light Company, Limited, of the one part, and the Compagnie Continentale Edison de Paris, of the other part, be and the same is hereby approved, and that the Directors be empowered to do all acts necessary for carrying such agreement into effect and constituting the new Company, and to enter into a further agreement to be made with such new Company." The Chairman explained that the further agreement referred to a bargain with the Edison and Swan Company not to make lamps for exportation in those countries protected by Swan's patents.

Mr. Leyland seconded the motion, and expressed an opinion that when the new arrangement was found to work well, Germany would reconsider its position and come to similar terms. He recommended entering into the agreement which had been described by the Chairman as the very best thing the Company could do.

The motion was carried unanimously, and the proceedings closed with a vote of thanks to the Chairman.

FACETIÆ.

THE LUMINOUSLY BRIGHT YOUNG MAN (after "Patience"), by Henry Hince.

I.—If you're anxious for to shine

In the electric lighting line,
As a man of science hold,
You must run down torches flaring,
Lamps and gas and candles glaring,
And sneer at them as old.
You must crack up commutators,
Armatures and inductors,
Quantity, intensity and field of force,
Incandescence, insulation,
And magnetical rotation,
Which is soon to light the world, of course.

And every one will say,

As you walk your brilliant way,

If this young man is such a bright young man,
As to be too bright for me.

Why, what a very luminously bright young man,
This bright young man must be.

II.—If you want to sell a plant,

You must get up all the rant,
You can—pound into your brain,
You must shoot it off your tongue,
To the people you're addressing,
Like a limited express train.
You must make all men believe,
That you never is deceiving,
You'd rather burn your tongue off in the fire
And this in spite of knowing,
While the words are from you flowing,
That you're a most outrageous liar.

And every one will say,

As you walk your brilliant way,

If this young man is such a bright young man,
As to be too bright for me.

Why, what a very luminously bright young man,
This bright young man must be.

III.—Your lamps for incandescence

Are the concentrated essence
Of all that makes good light,
Your dynamo must efficient,
Your experts an endorsement,
You point all ad libitum tight,
The other fellow a stall,
Is every crack and cough,
His arguments poor and low.
Follow close these indications,
Steer clear of electricians,
And you'll get them all the same.

And every one will say,

As you walk your brilliant way,

If this young man is such a bright young man,
As to be too bright for me.

Why, what a very luminously bright young man,
This bright young man must be.—*Western Electrician.*

PROVISIONAL PATENTS, 1888.

MAY 25.

7655. Improvements in and connected with underground conductors of electricity. *Roeke Evelyn Bell Crompton, Ave Works, Chalmersford.*
7679. Improvements in electric lamps. *John George Sowerby and Charles John Chubb, 11, Wellington street, Strand, London.*
7696. Improvements in incandescent electric safety lamps. *Theophilus Coad, 1, Quality court, W.C.*

MAY 26.

7748. An electric motor for clocks, watches, and other similar apparatus. *Louis Hoppe and Gunther Hoppe, 33, Southampton-buildings, Holborn, London.*
7750. Improvements in electric arc lamps. *Julien Dulait, 28, Southampton-buildings, London, W.C.*

MAY 28.

7761. Improved method of applying electricity to a general system of traction. *Charles Barnard Burdon, 32, Holborn hill, Higher Tramore, Cheshire.*

MAY 29.

7805. Improvements in the method of and apparatus for the production, transmission, and distribution of electric currents. *Herbert John Allison, 52, Chancery-lane, London. (Charles Edgar Fritts, United States.) (Complete specification.)*
7826. Improvements in galvanic generators. *Harry Barnuger Cox, 46, Lincoln's-inn fields, London, W.C. (Complete specification.)*
7848. Improvements in or relating to indicators for alternating electric currents. *William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.) (Complete specification.)*
7849. Improvements in or relating to apparatus for detecting and locating faults in alternate electric circuits. *Wm. Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.) (Complete specification.)*
7850. Improvements in or relating to alternate current electric distribution. *William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.) (Complete specification.)*
7851. Improvements in switches for electric circuits. *William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.) (Complete specification.)*
7852. Improvements in or relating to central-station apparatus for system of electric distribution by alternate currents. *William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.) (Complete specification.)*
7853. Improvements in or relating to storage batteries. *Wm. Phillips Thompson, 6, Lord-street, Liverpool. (Charles David Paige Gibson, United States.) (Complete specification.)*
7876. Improvements in electric batteries. *Benjamin Wilcox, 47, Lincoln's-inn fields, Middlesex. (Bruno Abdank Abakanowicz and Arsene d'Arsonval, France.)*

MAY 30.

7901. Improvements in the construction of electro, medical, and other magnets. *James Joseph Horne, Lougham, Gresson-hall, East Dereham, Norfolk.*
7910. Improvements in holders for incandescent lamps. *Fredk. Thomas Schmitt, Sunningdale Chambers, Bradford, Yorkshire.*
7916. Improvements in transmitting written or other characters, figures, drawings, plans or the like, and also indicating and recording the indications of registering instruments by electricity and in apparatus therefor. *Thomas O'Brien, 6, Bank street, Manchester.*

MAY 31.

7977. Improvements in the mode of filling secondary battery plates. *Henry Garney Harris and Pedro Grotjan Salom, 320, High Holborn, London, W.C. (Complete specification.)*
7998. Improvements in and relating to shades and reflectors for incandescent electric lamps. *Frank Holman, 45, Southampton-buildings, London. (Complete specification.)*

COMPLETE SPECIFICATIONS ACCEPTED.

MAY 31, 1887.

7865. Improvements in dynamo-electric and electro-dynamic machines. *Frederick George Uley, Dursley, Gloucestershire.*

JULY 13, 1887.

9043. Compensating electric measuring instruments for temperature. *Walter Thomas Gellien and Sydney Evershed, 2, Victoria Mansions, Westminster, S.W.*

JULY 28, 1887.

- 10,519. Improvements in posts, such as fencing telegraph, direction, lamp, and other similar posts. *James Bazeley Potter, 34, Southampton-buildings, London, W.C.*

JULY 30, 1887.

- 10,600. Improvements relating to the distribution, storage, and regulation of electric currents. *Levi Gerard, 433, Strand, London.*

AUGUST 4, 1887.

- 10,748. Improvements in portable batteries for the production of electric light. *Alexander Schanckeloff, Epsley-hill, Surrey.*

SEPTEMBER 17, 1887.

- 12,645. Improvements relating to means for carrying electrical batteries for driving tramway vehicles, and for other purposes. *William Danton Sandwell, 4, South street, Finsbury, London.*

SEPTEMBER 26, 1887.

- 13,005. Electrical automatic boxes for the delivery of small articles. *Frank Vanders Staal, Edward Rastall Hodgkiss, and James Spratt, 1 and 2, George-street, Mansion House, E.C.*

OCTOBER 14, 1887.

- 13,954. Improvements in or appertaining to electrical railways. *William Edwin Irish, 52, Chancery-lane, London.*

JANUARY 31, 1888.

1406. Portable combined electric and mechanical clock alarm. *Mary Torton and Samuel Torton, The Ley-road, Tipton.*

FEBRUARY 7, 1888.

- 1851A. A sound conveying tube for telephones, graphophones, and like instruments. *James Yate Johnson, 47, Lincoln's-inn-fields, Middlesex. (The Volta Graphophone Co., Incorporated, United States.) Note—This application having been originally included in No. 1851, dated 7th February, 1888, takes, under Patents Rule 23, that date.*

FEBRUARY 14, 1888.

2218. Improvements in compasses, calipers, and analogous instruments. *Joshua Stevens, 169, Fleet street, London.*

MARCH 20, 1888.

4273. Improvements in the method and means for increasing the frictional contact between the wheels and rails in railways. *Alfred John Boulton, 323, High Holborn, Middlesex. (Elias Elian Rens, United States.)*

MARCH 24, 1888.

4524. Improvements in portable galvanic batteries. *William Joseph Starkey, Bartholomew Starkey, 70, Market-street, Manchester.*

APRIL 27, 1888.

6237. Improvements in jars or cells for primary or secondary electric batteries. *Adam Miller, 62, St. Vincent street, Glasgow.*

MAY 1, 1888.

6416. Improvements in galvanic elements. *Louis Hoppe and Gunther Hoppe, 6, Annette road, Lonsdale road, Holloway, London, N.*

6481. Improvements relating to the electrical transmission of power and to apparatus therefor. *Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.)*

6502. Improvements relating to the generation and distribution of electric currents and to apparatus therefor. *Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.)*

SPECIFICATIONS PUBLISHED.

CITY NOTES.

Western Counties and South Wales Telephone Company.—The Directors of the Western Counties and South Wales Telephone Company announce a dividend of 6 per cent.

Hastings Electric Light Company.—At the annual meeting of the Hastings Electric Light Company, a dividend of 3 per cent. was declared. The gross profits were £558. 18s. 7d.

Direct Spanish Telegraph Company.—The traffic receipts of the Direct Spanish Telegraph Company for the month of May amounted to £1,800, against £1,568 in the corresponding period last year.

Eastern Telegraph Company.—The Eastern Telegraph Company's traffic receipts for the month of May, 1888, amounted to £49,003, compared with £48,057 in the corresponding period of 1887.

Brazilian Submarine Telegraph Company. The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending May 25 amounted to £4,125; and for the week ending June 1, £3,376.

The American Edison Incandescent Lamp Patents.—It is announced that Mr. Arthur Sloppy has been retained as an expert witness by the Westinghouse Electric Company in the legal proceedings pending in the U.S.A.

Union Electrical Power and Light Company. Mr. H. Evans Broad (Broad, Paterson and Co., chartered accountants) has been appointed by Mr. Justice Chitty official liquidator of the Union Electrical Power and Light Company.

The Sawyer-Man System.—Mr. Frank Ritchell, of New York, the authorised agent of the Sawyer Man Electric Company, is at present in London making arrangements for the introduction of the Sawyer Man system of electric lighting.

Eastern Extension Telegraph Company. The traffic receipts of the Eastern Extension, Australia and China Telegraph Company, for the month of May, 1888, amounted to £40,586, compared with £36,486 in the corresponding period of 1887.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company for the half month ended May 31 are £2,991, as compared with £3,438 in the corresponding period of last year. The February receipts, estimated at £6,449 realised £6,625.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during May was 4,437, estimated to produce £3,300 against 4,040 messages producing £3,061 in the corresponding month of last year. The traffic receipts for February, estimated at £3,600, realised £3,666.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ending May 25, after deducting the fifth of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, were £3,366, and for the week ending June 1, after deducting the fifth of the gross receipts payable to the London Platino Brazilian Telegraph Company, Limited, £2,675.

United Telephone Company. The Directors of the United Telephone Company have decided, subject to audit, to recommend, at the forthcoming general meeting, a dividend for the second half year ending April 30, 1888, at the rate of 10s. per fully paid share, and 5s. the new shares, making, with the interim dividend paid on December 2 last, a total dividend for the 12 months ending April 30 last of 15 per cent. Dividend warrants will be posted on July 3.

The Telephone Market.—The monthly circular of a firm of stock brokers which devotes special attention to telephones says: "Telephones have been a quiet market, and prices close flat. The negotiations for the amalgamation of the various interests hang fire. The central vice which has characterised all the operations of the United Telephone Company since its formation—namely, endless procrastination and inaction in place of action—is no doubt the cause. The shareholders of this company, having received good dividends, seem quite content to remain ignorant of, or to ignore, the shortcomings of their Directors. But for the happy accident that subsidiary companies were formed whereby the management in certain districts was transferred to other hands, the United Company's dividends would have been small. The Company, in fact, is to-day successful, not owing to the exertions of its management, but really in spite of the fact that its best interests have been neglected, and its most important field of operations left practically unworked."

Consolidated Telephone Company. The report of the Consolidated Telephone Construction and Maintenance Company, Limited, for the year ended March 31, 1888, states that the net profit amounts to £10,788, which, with the amount carried forward from last year, leaves a balance of £12,484 for disposal, after making provision for doubtful debts. It is proposed to pay a further dividend of £2 17s. per cent, making, with the interim dividend paid in November last, £5 7s. per cent for the year, writing off the sum of £541 for depreciation of plant, machinery, and furniture, and the sum of £2,000 for the Mason Tower Bell Telephone Company securities, thus leaving a balance of £1,372 to carry forward. The Directors have received a further sum of £4,427 on account of profit arising from the liquidation of the River Plate business, which is included in the above statement, and there is still a further considerable amount to be received under that head. They have received an interim dividend at the rate of 5 per cent on the shares of the United River Plate Telephone Company, which is also included in the foregoing.

NOTES.

Japan.—A central station is to be shortly opened at Yokohama on the Gulcher system.

Motors for Paris.—Sprague motors in considerable quantities have been ordered for Paris.

Vienna.—The number of lamps in the Vienna Town Hall will be shortly increased from 650 to 2,000.

Electric Light Act.—The Electric Light Amendment Act has passed through Committee in the House of Commons.

Maxim-Weston Company.—The meeting of share holders of this company takes place to-day. A lively meeting is expected.

Gas and Electricity in France.—The gas company at Eprenay have decided shortly to establish an electric central station in that town.

Motor Installation.—San Francisco, California, is going ahead with distribution of electric power for motors. It has 700 motors at work, employing five circuits.

Electric Fishing.—Some German sea fishermen are making experiments with the electric light for night fishing, and so far the results have been highly satisfactory.

Electric Physiology.—M. Augustus Waller read a paper on 28th May, before the Société Savantes, on "The Determination of the Electromotive Action of the Human Heart."

Licence for St. James's.—The St. James's and Pall Mall Electric Light Company were yesterday week granted, by the Vestry, a license for the supply of the electric light in the parish of St. James's.

Derby.—Messrs. John Davis and Son, who supply the light to the exhibition at Derby, are intending, we understand, to put down a large electric plant at their premises, All Saints' Works, for supplying the neighbouring shops.

Paris.—The Edison Continental Company has commenced work for the establishment of a central station at the Palais Royal, Paris. The machinery is to be fitted underground. The station will contain six Edison dynamos for 1,000 lamps each.

Italian Exhibition.—The theatre at the Italian Exhibition is lighted entirely by electric light from the Thomson-Houston incandescent dynamo. There is not a single gas-bracket about the place. The lamps are arranged to be turned up or down as desired by a variable resistance.

The Gas Company can do it.—At Verona a local electric light company which was formed for establishing a central station, not being able to fulfil this object, the gas company has been authorised by its shareholders to take the matter in hand, and turn the dynamos for the Veronese.

Electric Traction in Berlin.—The Schwartzkopf Company, of Berlin, have just constructed a new electric tramway. The current is furnished by a battery of 60 cells, with a capacity of 320 ampere-hours. The motor is a disc dynamo, with double winding on the armature, and two commutators.

Slate Bases Not Good Enough.—The installation at the Burg Theatre, Vienna is now complete, but the Vienna Society of Electricians, having officially examined it,

have declared that the insulation furnished by the slate bases of the cut-outs and other similar parts is not sufficient for them to pass the installation.

Large Installations.—One of the largest, if not the largest, central electric station at present working is that of New Orleans, where the Louisiana Electric Light and Power Company have an installation of 1,500 arc lights, with 350 miles of circuit. Plant for 1,800 incandescent lamps has also recently been added to the system.

Royal Meteorological Society.—At the ordinary meeting of the society, to be held at the Institution of Civil Engineers on Wednesday next, among others, the following paper will be read:—"First Report of the Thunderstorm Committee. On the Photographs of Lightning Flashes," drawn up by the Hon. Ralph Abercromby, F.R.M.S.

Milianah.—The town of Milianah, in France, is to be lighted with electric light, under the direction of M. George Gally. The installation will have two 300-light dynamos, driven by a turbine of 60 h.p., at a distance of 500 yards from the town. The streets will be lighted with seventy lamps of 16 c.p., and twenty lamps of 50 c.p. The installation is to be ready by July 14.

Electric Lights on the Railway.—On a block system of the South Pacific Railway, California, the oil lamps in the signals are replaced by Swan incandescent lamps on an arc circuit. Forty trains after dark run on this line, and the electric lamps are not blown out by the high winds, as is the case with the oil lamps, and two less men are required to clean the lamps.

The Poetry of Induction.

"Around the magnet, Faraday
Is sure that Volta's lightnings play;
But how to draw them from the wire!
He took a lesson from the heart;
'Tis when we meet, 'tis when we part,
Breaks forth the electric fire."

Blackwood's Magazine.

Irish Exhibition.—The electric lighting at the Irish Exhibition is that permanently installed at the opening of Olympia, with groups of six-starred arc lamps in lanterns, which make this one of the best-lighted halls to be seen. Messrs. Edmundson and Co., Limited, the well-known electrical engineers, of Great George-street, Westminster, exhibit some models and specimens of their lighthouse fittings.

Royal Society.—The following papers, by Mr. G. Gore, F.R.S., were read yesterday before the Royal Society:—(1) "The Minimum Point of Change of Potential of a Voltaic Couple." (2) "The Change of Potential of a Voltaic Couple by Variation of Strength of its Liquid." (3) "Influence of the Chemical Energy of Electrolytes upon the Minimum Point and Change of Potential of a Voltaic Couple in Water."

Magnetic Filter for Old Oil.—A new process has been invented for cleaning lubricating oil that has once been used, so that it can be used again. The oil is poured gently over a bed of iron which is strongly magnetised. The heaps of iron fragments constitute a magnetic sponge which stops all the particles of metal, especially those of iron. The oil is then passed through two hair filters, and comes out perfectly clean.

Accumulators on Board Ship.—It is satisfactory to note that accumulators are to be employed in connection

with the electric light installation which is being put into the Queen's yacht "Victoria and Albert." The battery is to consist of forty of Messrs. Drake and Gorham's latest type ship-lighting cells, which will be used in conjunction with a special switch board designed by the same firm, and fitted with their patent ring contact switches.

Incandescent Lamps for Boiler Inspection.

Mr. E. Blass, a German scientist, has used an incandescent lamp for actual inspection of the inside of boilers under steam. A thick glass tube was introduced through a stuffing box, a small incandescent lamp was lowered into this, and lighted by means of a small battery. By this means the whole of the boiler was lighted up, and could be inspected through a thick glass plate inserted in the boiler.

Election F.R.S.—The new members elected by the Royal Society are:—Thomas Andrews, F.R.S.E., James Thomson Bottomley, M.A., Charles Vernon Boys, Arthur Herbert Church, M.A., Prof. Alfred George Greenhill, M.A., Lieut.-General Sir William F. D. Jervois, R.E., Prof. Charles Lapworth, LL.D., Prof. T. Jeffery Parker, Prof. John Henry Poynting, M.A., Prof. William Ramsay, Ph.D., Thomas Pridgin Teale, F.R.C.S., William Topley, F.G.S., Henry Trimen, M.B., Prof. Henry Marshall Ward, M.A., and William Henry White, M.I.C.E.

Cut-Outs.—The best general rule for the use of cut-outs is not, that each branch from a larger wire should have a cut-out at the junction, as often insisted upon in specifications, but as follows:—(1) Every main to be protected by a single-pole cut-out on each cable, negative and positive, and every branch main to be similarly protected with two cut-outs; and (2) every group of lamps, either in a row, or in an electrolier, up to the number of 10 or so, to be protected by a single-pole cut-out (or by a double-pole cut-out if preferred); and (3) every single pendant having its junction off the main should have a double-pole cut-out.

Speed of Electricity. According to Prof. Gould's investigations, it appears that aerial telegraph wires on poles transmit electricity at the rate of from 14,000 to 16,000 miles per second, and that the velocity of the transmission increases with the distance between the wires and the earth, or, in other words, with the height of suspension; and that subterranean wires, like submarine cables, transmit with reduced rapidity. Again, while wires suspended at a feeble height are known to transmit signals at a velocity of some 12,000 miles per second, those that are suspended higher give a velocity of from 16,000 to 24,000 miles.

Damage by Lightning.—In Mr. Reginald Jones' paper on "Breakdowns," the question was asked whether cases were known where lightning had damaged installations. At Seward, in Nebraska, there is a 600-light installation on the Westinghouse transformer system, which has been working well for some time. During a recent storm the lightning struck the wires and broke down seven convertors. The circuit was temporarily deranged, but the damage was not as great as might have been expected, and by rewinding a portion of the convertor and borrowing a few others the trouble was remedied without much delay.

Origin of the Aurora Borealis.—M. Luvin has expounded a theory of the aurora borealis. The friction of the particles of water, ice, and, accidentally, of other substances caught up by the violence of the atmospheric disturbance into the higher regions, and dispersed in the upper layers of the air many miles high, is the source of the

atmospheric electricity, thunderstorms, and the aurora. The discharges of this electricity takes place in the same manner in auroras as in thunderstorms, the only difference being their intensity; and it is owing to these discharges in the rarefied air that the light of the aurora has its origin.

Toulouse.—The central electric light station at Toulouse will shortly have a great extension. It has been established now some months, and the director, M. de Chanteau, has now obtained permission from the authorities to run his conducting mains along the main sewers, and he will also be able to utilise the falls at Bazacle, from which power can be obtained up to 1,200 h.p. The gas company at Toulouse had been contemplating for some little time setting up a central station of their own, but, in the usual manner, have left the matter sufficient time for their competitor to put up an installation, and become master of the situation.

Aphorisms for Gas Companies.—"What difference does it make to a gas company whether the money expended on improvements be for gas-holders and mains, or for dynamos, boilers, and wire?" "Consumers will have the electric light, if it costs twice as much as gas. It is good policy for the gas companies to recognise this fact, and govern themselves accordingly." "The introduction of an incandescent plant into the business district of a town means the loss of a five-foot burner for every incandescent lamp used." "Gas companies are much more favourably situated for furnishing arc and incandescent lamps and electric power than anyone else at present."

Benevolent Society.—The 12th annual meeting of the United Kingdom Postal and Telegraph Service Benevolent Society was held last week in the Town Hall, Oxford. About 120 delegates from various parts of the country were present. In the evening the delegates were entertained at dinner by the staff of the Oxford branch of the society, the Postmaster of Oxford presiding, supported by the Mayor and other gentlemen. The society numbers upwards of 13,000 members, the increase during the past year being over 1,300. More than £56,000 has been paid in benefits since the formation of the society. The next annual meeting is to be held at Belfast. It would be well if the electrical engineering industries were to imitate the example of our telegraph confrères.

Schanschloff Battery Company.—This company is still *in statu quo*. We have noticed a report in a French contemporary, that at a general meeting of shareholders it has been decided to wind up, and refund the money; but this is not the case. The company have taken very fine premises in Baringhall-street, and were laying themselves out for great business in mining and other lamps before the injunction was obtained, which is not yet settled. Even if settled satisfactorily to the company, it is hard to see how they can move business to the extent of their capital; and the directors are, no doubt, feeling this, and a readjustment of the amount of capital and the terms of purchase may possibly be looked for. If this be so, we shall look with some hopes that the company may be longer lived than many of its predecessors.

Hungary.—Most of the stations and flour mills of Hungary and many of the principal factories are using the electric light. At harvest time a portable installation is often used to pursue the work at night during the absence of the moon. The town of Temesvar has no other light. Many of these installations are undertaken by Messrs. Ganz

and Co., who are using the transformers of Zipernowski, Deri, and Blathy to a large extent. The travelling installation, mounted on a railway waggon, with dynamo and arc lamps, supplied by this firm, which was illustrated in this journal a few weeks ago, is greatly used for embanking or discharging troops by night. Messrs. Dollinger and Paragh, of Buda Pesth, make electric apparatus for physicians and surgeons, and several other firms in Buda-Pesth, are actively engaged in various electrical developments.

Switzerland. For some time past the transmission of electrical current for light and power by utilising the falls of the Swiss waters has been successfully carried out. A scheme of national importance is now mooted by a Swiss engineer, Herr Zschokke, of Aarau, for the purpose of utilising to a far greater extent the vast resources of water-power in Switzerland. It is calculated that in Switzerland some 68,000 h.p. is used in factories, of which two-thirds is water-power and one-third steam power. For this latter, and for the locomotives, which take a further 175,000 h.p., large quantities of coal are imported annually from Germany, France, and Belgium a total expenditure of 18,000,000*f*. Herr Zschokke proposes the construction of colossal reservoirs upon the various rivers, and the utilisation of these and the various waterfalls for the employment of electrical transmission of power instead of the continued use of steam and gas engines.

Electric Traction in France.—In the department of Haute-Savoie, a local railway is to be established on which electric traction is to be used. The concession has been obtained by Messrs. de Meuron et Cuénod, of Geneva, for a period of sixty-five years; a period of six months is to be allowed before commencement, and the entire line is to be opened within two years from the commencement of the work. A minimum is fixed of four trains per day each way. The following are the official conditions:—"The trains must be put in motion by electricity. For this purpose each carriage will carry a receiving dynamo electric machine, put in communication by means of a copper cable laid the length of the line, with the generating machine driven by stationary steam engines, placed at Monnetier, half the total distance. Each carriage must be mounted with an electric regulator, a friction break and an automatic break." This will be the first enterprise of the kind established in France, and its development will be watched with considerable interest in all parts.

Long-distance Telephoning.—The National Telephone Company, having a central office at Edinburgh, have connected that town with the surrounding towns in a network of communication, so that Edinburgh is now in telephonic communication with Glasgow, Paisley, Greenock, Ayr, Kilmarnock, Broughty Ferry, Newport, Perth, Forfar, Arbroath, Cupar, Kirkcaldy, Dunfermline, Alloa, Clackmannan, Stirling, Falkirk, Grangemouth, Linlithgow, and other towns. The tariff for conversation is 6*d.*, or one shilling for three minutes' conversation according to distance. Each of the subscribers by signing a simple agreement can converse on demand, from his own office or house, with subscribers in any of the other towns connected. A careful record of such connections is kept, and the company renders an account at the end of every month. They have issued a neat little pocket guide for the use of subscribers. In Switzerland, Genf and Lausanne are to be connected with Basle and Zurich on the Ryssolbergh system.

School of Electrical Engineering. The managers of the School of Electrical Engineering and Submarine Telegraphy, Hanover square, have appointed Mr. Charles Capito, Member of the Institute of Mechanical Engineers, M.S.T.E. and E., to the post of Senior Instructor, shortly to be vacant by the resignation of Mr. Henry D. Wilkinson. Mr. Capito was for three years apprenticed to mechanical engineering works in Copenhagen, and studied for seven years in the Polytechnical Academy there, passing all the examinations with the highest honours. From there he went to Greenland, as a consulting engineer to the Krysolite Mining and Trading Company. He came to England (where he has since resided) in 1880, and for about two years held office in the City and Guilds of London Institute at Finsbury, under Prof. Ayrton, where several men now well known in the electrical world were his pupils. He became chief electrician to the Electrical Power Storage Company, whose employment he left, desiring to go into business for himself as a consulting engineer.

The Police Telegraph System.—Since the riots which took place in the West-end and the meetings of the unemployed in Trafalgar-square the attention of the authorities has been directed to the perfection and extension of the police telegraph system throughout the metropolis. The result has been that during the last few months London has been intersected by a network of wires for the special use of the metropolitan police, and under the present conditions the concentration of a large body of police officers in any part of London on the shortest notice would be a comparatively easy matter. The system has been carried out on an extensive scale. The central police offices are also connected by either telegraph or telephone with the Fire Brigade stations, the War Office, the Home Office, the House of Commons, and the House of Lords, as well as with the private residences of the superior officers. In addition to these extensions, in case of emergency a message handed in at any postal telegraph office by a police officer is to take precedence of any others.

Electric Soldering and Welding.—Since the first successful trials of the Bernados system of electric welding, various disadvantages have begun to make themselves apparent. A German engineer, G. Kamienski, in the *Chemische Zeitung*, gives some particulars with reference to the process. The high temperature of the electric arc is not only very harmful to the eyes, but, it is stated, affects the skin of the face, peeling off the surface skin, and sometimes even causing wounds. The dark glasses hitherto used are too heavy and too dark, and occasionally it is necessary, in order to see clearly the progress of the work, to take them off, with great danger to the eyes. The silk masks which have been tried are impractical, and also obstruct the breathing. The great luminosity of the arc besides, though not noticeably hot at a short distance, evidently affects the nerves in the manner of sunstroke. A curious feeling is noticed by bystanders at the nape of the neck, which renders them giddy and uncomfortable; and persons who have already suffered from an attack of sunstroke are threatened with a renewal of the symptoms under the glare of the arc.

The Noises of an Engine. Every steam engine has certain well-defined sounds in action, which we call noises for want of a better term, and it is upon them and their continuance that an engineer depends for assurance that all is going well. So soon as the sequence or continuity of certain sounds is interrupted, the engineer hurries

into the engine-room to see what is amiss. Curiously enough, compound engines and modern systems, triple and quadruple expansion engines, and high pressures have greatly affected the method of judging whether all is going well or not. "Modern engines play all sorts of tunes," said an engineer to us lately, "and it bothered me greatly to get used to it for a while. Everything would be going well and apparently in harmony for an hour or so, when suddenly the tune would change and another strike up from some cause or another that I have never yet been able to find out, but since I have discovered that it makes no difference in the action of the machine itself I don't bother about it, although it is very annoying." This peculiarity refers to marine engines chiefly, but it may also to stationary engines on the same system, and it is one of the innovations which engineers have to become accustomed to.—*American Engineer*.

Legal. The plaintiffs in the action of Morgan v. Prichett were two ladies, the owners of two houses in Hanway place, Oxford-street, which are let in flats to weekly tenants, and two of their tenants. The defendants are Messrs. Prichett, who supply, from premises adjoining, electric light to the neighbourhood. The plaintiffs complain that the engines and dynamos of the defendants have been so worked as to produce a nuisance to the tenants, who all occupy the premises as dwellings, by reason of the noise and vibration. The plaintiffs seek an injunction to restrain the defendants from working their machines so as to be a nuisance. The action was now brought on on notice for an interlocutory injunction. There was some conflict of evidence, but the parties were agreed that on a certain occasion, on the evening of the 14th ult., when representatives of both sides were present on the plaintiffs' premises, the works were being carried on so that no substantial nuisance existed. It was stated, in answer to the judge, by counsel for the defendants, that there was record in the defendants' office that their tension meter indicated at that time a resistance of from 100 to 105 volts, and that of the two steam-engines employed by the defendants the smaller was governed to work at, and did on that occasion work at, the speed of 180 revolutions a minute, and the larger one at the speed of 120 revolutions a minute, and he offered to give an undertaking on behalf of the defendants to keep the working within those limits till the trial. His lordship said that one of the defendants' witnesses, cognisant of the matter, must make an affidavit as to the conditions of the working during the three-quarters of an hour in question, and the defendants would undertake to work within the limits of such conditions.

Langham Hotel.—The largest installation hitherto lighted from a central station in England has just been lighted up at the Langham Hotel, Portland-place. This hotel, which is one of the largest in London, is now practically lighted throughout with electric light, the total number of lamps being 1,600, and a further 100 are still to be lighted in the top floors. The current is supplied from the Grosvenor Gallery, the main primary wires entering a separate fire-proof converter-room outside the building in a courtyard of the basement. This room contains five large converters, with their separate fuses, and the secondary cables are run in several groups, of about 200 lights each, to the various departments. The wiring and fittings have been carried out by Messrs. Verity Brothers, of Regent street, with Mr. J. H. Cudde,

121, Cannon-street, as consulting electrician. The whole of the wiring is practically surface wiring, and fuses are put to all pendants. In the coffee-room the pendants are combination electroliers, with gas jets above and electric lights below, handsomely wrought and gilt decorated work, with iced shades, two ten-light and two six-light electroliers to each large room. The passages are fitted with similar iced shades, each with a socket switch, and the ladies room and private sitting-rooms have movable standard lamps. The dining-room has a long row of pendants, with large frosted bells, each containing three lamps, which are run two in series, one lamp in each series in the next pendant. Long, neat, mahogany boxes, glass covered, enclose the switches, which are Verity's patent sudden break tap switches, together with the corresponding double pole fuses, on china bases, with metal plug fuses. The whole of the work is conveniently arranged, and the size of the installation is a striking proof of the manner in which distribution from central stations is progressing in London.

E.P.S. Accumulators. Great strides in the development and general efficiency of accumulators have been made lately by the Electrical Power Storage Company. Batteries hitherto capable of yielding 30 amperes discharge for ten hours now yield 45 amperes with the same weight of material, an improvement which is equal to a saving of 50 per cent. in the cost. The Hammersmith omnibuses are now lighted with electric light supplied by special small box accumulators placed under the drivers' seats. Fifty or sixty of these have been in use some time, and the number will be shortly increased to 200. The Omnibus Company have a small gas-engine and dynamos at their Hammersmith shed, to charge the accumulators every night for use next morning. Medical batteries, for use at the various London hospitals, and for private physicians, are also in great demand, these are supplied ready charged by the company, who send for them to be recharged. They have also brought out a stronger and more compact form of battery for traction work, and there seems to be considerable activity promised in this direction, judging by the number of traction Syndicates stirring. The promised development in storage systems advocated for the R.T. system of distribution from central stations will open fields for supply of accumulators of as much larger type than those at present in use as a modern gasometer is larger than a tin cistern. The Electrical Power Storage Company will be able to tackle these requirements as they arise, and at the present moment are able to supply batteries with plates the size of a dining-room table, having a capacity of 800-900 lamps for 10 hours. Their licensees in all parts of the world are extremely busy, especially in America, and we notice that, with respect to the far-famed Julien battery, the American owners of the patent are bringing an action-at-law with reference to the infringement of their patents.

New Types of Storage Cells. Details of new types of accumulators are arriving from all parts of the world. The wonderful effect of science in utilising waste products, now so noticeable with our friends and rivals the gas companies, lately culminating in the production of sugar, in the form of saccharine, from the once despised coal-tar, and which for the electrician has evolved the reversible or storage cell from the electrical waste product "polarisation," is destined in time to absorb the *raison d'être* of gas and coal-tar combined at any rate in their original capacity of house lighting. We invite attention to the detailed description we give elsewhere of the copper accumulator of Messrs.

Commelin, Desmazure, and Baillehache, about which we gave a report a week or two ago, with reference to their performance at a test trial with a screw launch at Havre. These cells are now made in a commercial form, but the chief objection to them seems to be the high electro-motive force (1.2 volts) in charging, against the discharging potential of 0.75 only. The lasting power of these cells is also not stated. In Spain, we hear of a new type of accumulator giving greatly increased charge and accelerated speed of discharge with the same weight of material, and although particulars are withheld, there is evidently great activity in various fields to bring to perfection this means of accumulating electrical energy. In Germany, in Hagen, Westphalia, Messrs. Busche and Muller have just erected a large accumulator factory for the production of a new type of accumulator, the invention of Messrs. Tudor Frères. Nothing has, up to now, been published with reference to the experiment of the inventors, who have for the last eight years been diligently studying the subject, and have been able to introduce, it is stated, some very important improvements. In the Tudor accumulator the oxide is crystallised in a hard structure upon an underlying lead plate, and is not liable to scale; the wear and tear by use is almost entirely obviated. The factory will be able to turn out plates in very large quantities, and in a few months will be in a position to supply sets of accumulators with elements of 2,000 ampere-hours capacity, with a rate discharge of 500 amperes. This firm has received a large order for accumulators for the State Theatre at Darmstadt, for which they have given a five years' guarantee.

The Julien Electric Railway.—We have received the following particulars from the Julien Company, of New York. It is now some eighteen months ago since the Julien Electric Company, of New York, obtained from Brussels a storage battery electric car, and put it in service on the streets of New York City. It has been in use on Mr. Vanderbilt's road, running from Eighty-fifth-street and Madison-avenue to City Hall, for about a year, and has given such satisfaction that Mr. Vanderbilt, the president of the New York and Harlem Railroad Company, has made a contract with the Julien Electric Company to place ten electric cars in service on their road forthwith. To that end, the Julien Electric Company are now installing an electric station at Eighty-fifth-street and Madison-avenue with sufficient generating machinery to run the ten cars. The station is nearly finished, as are the cars also, and the system will be in operation about the end of June. The station has two 75 h.p. tubular boilers and two 75 h.p. straight line engines, and two Weston dynamos of the capacity of 300 volts and 85 amperes each. The batteries for the cars are inserted in and removed from the cars by means of a shifting device, which is run by an electric motor. Sufficient batteries for the ten cars are arranged in tiers on either side of the pit over which the car is run, in a way to best subserve economy of space. The cars are 18 ft. long. The car body is mounted on two four-wheeled trucks, each truck carrying a 12 h.p. motor, Julien type. Chain-gearing is used; the car body is pivoted on the trucks, and in this way will describe with ease the very sharp curves to be found in American street railways. The car carries 120 cells of the Julien battery, arranged 60 on either side of the car; each cell has a capacity of two volts and 120 ampere-hours; they are coupled in series or in parallel by means of the Julien regulator; they are run in series most of the time, thus economising the expenditure of energy much more than when run in parallel. The cars are to be elegantly

fitted up, and to be far superior in interior decoration and finish to any street-car hitherto used in America. They will be run from the Grand Central Depot, at Forty-second-street and Fourth-avenue, down town to the Post-office and back. The street railway companies of America are awaiting with great interest the result of this installation; if it is successful, as we have every reason to hope, electric traction by storage battery will become a great industry in the United States.

New Edition of the Phoenix Rules.—The thirteenth edition of the Phoenix Fire Office rules is now issued, the large number of copies of the twelfth edition being completely exhausted. In the new edition, Mr. Musgrave Heaphy has embodied still further improvements in minor matters, such as cut-outs, and to deal with modern developments of high-tension currents for charging in central station lighting by the battery or B.T. system. The recurring sentence, allowing exceptions under certain conditions by permission of the inspector, found at the end of several of the rules, and which was objected to at the recent discussion, has been removed from those positions, and a note is inserted at the end of the rules, in these words:—"No departure from any of these rules will be allowed, unless permission is given by the inspector from the Fire Office." With regard to the question which has been actively discussed, as to the danger of multiplication of cut-outs, the rule now stands in the way. After stating that, as a general rule, when a branch is led off any conductor, a fusible wire must be inserted near the junction, which should fuse at 50 per cent. above the safe capacity of the wire, or 100 per cent. above the normal when this is below the safe capacity—the rule goes on to say:—"If, however, a branch is already protected by 'cut-outs' on the mains, or on a superior branch, then it may not be necessary to again protect it by other cut-outs, unless required to do so by the inspector of the fire office. It is as well to protect all positive and negative principal branches by fusible cut-outs. This must be done when transformers, accumulators, or primary batteries are used; also when small branches are taken directly off the mains. . . . When lights are grouped, as upon electroliers, &c., the small wires to each light cannot always have cut-outs. Care should be taken, however, that the last controlling cut-out carries as small an amount of current as practicable, and that it will act before the smallest wire runs any risk of getting unduly heated." The rule with regard to accumulators and high tension currents is as follows:—"When high tension currents are used from a central station (or other place) to charge accumulators, and secondary house circuits having a current of lower potential than that of the primary circuit are taken from the accumulators, then it would be preferable if these secondary conductors were provided with a device or arrangement by means of which their connection with the accumulators during the time these latter were being charged would be prevented. A current having an electromotive force of 500 volts or upwards, will be considered as a high tension current for this purpose." The bringing of these rules in this prompt and reasonable manner up to date will still further increase the regard with which they are held, and their general usefulness. The significant passage is still to be seen in the preface that "notwithstanding the number of years these rules have been in use, not a single fire has yet occurred from any electrical installation which has been placed up in compliance with them."

THE BRUSH TRANSFORMER SYSTEM.

MORDEY'S ALTERNATE CURRENT DYNAMO AND TRANSFORMER.

The first types of dynamos on a practical scale were alternate current machines, then came a period when continuous current machines only were fashionable, and now

and lighting by means of storage. Other engineers as eminent and as practical refuse to believe in any intermediary, and have pinned their faith upon storage. Whatever may be the ultimate evolutionary effect, we have to deal with carefully designed apparatus and schemes in both directions. The latest addition to alternate current dynamos is that designed by Mr. W. M. Mordey, of the Anglo-American Brush Company, in which the armature is

FIG. 1.—Armature. Mordey Alternator.

again we have a reversion of feeling towards alternate current systems. Undoubtedly, the reason for this is the introduction of the transformer, and the adaptability of the combined apparatus for practical work. Without venturing

stationary, and the principle of the iron-clad field has been adopted for the first time in alternate current machines so far as English constructors are concerned. The machine illustrated is intended to give an output of 35,000 to 40,000

FIG. 2.—Field. Mordey Alternator.

to be guided by American practice, many engineers have been impressed with the value of the transformer from its use in the Grosvenor Gallery installation, and believe it the intermediary between direct lighting from the machine

watts, with a terminal potential of 2,000 volts at a speed of 650 revolutions per minute.

The armature, Fig. 1, consists of coils of insulated copper ribbon, $\frac{7}{16}$ in. wide, wound on cores of non-conducting

material. The supporting cores are of porcelain, and each coil is bolted at the broad end, between two brackets, the ends of the conductor being brought out through porcelain insulators. The brackets are bolted to a gun metal ring, which for convenience of manufacture and repair is made in halves, the two parts being fastened together at the bottom and to the bed plate, and at the top by a special casting. The coils are thus rigidly and securely held in position by

The field-magnet, Fig. 2, consists of a single electro-magnet made as follows: a short wrought-iron cylinder, through the axis of which the shaft passes, forms the core, and is wound with a single coil of exciting wire, the ends of which are brought to two insulated gun-metal collectors. The exciting current is supplied by a small Victoria dynamo, by means of two brushes rubbing against the collecting rings, though other means may be employed for

FIG. 3.—Morley Alternator.

metal supports, which in no part come between the poles, and are, in fact, almost entirely out of the magnetic field. German silver is used for the brackets and bolts, because its high resistance assists in preventing local currents. A single armature coil is shown in the illustration, from which it will without difficulty be seen how the armature is built up. The coils in this case are connected in series, because an high E.M.F. is required; but any other combination can be obtained, the connections being regulated by the voltage or current required. It will be seen that the designer has carefully considered the important subject of repairs, and that

this purpose. Against each end of the above-mentioned cylinder is placed a cast-iron piece of peculiar form. Each casting has a number of arms—nine in the machine illustrated—which radiate from the shaft and central part of the casting, and then bend over, forming nine pole pieces on each side of the armature. These arms, as will be seen, approach each other from opposite sides, and in the gap between, the armature is held, the entire field magnet revolving with the shaft upon which it is held. This form of field-magnet is simple, and a single exciting coil suffices for a machine of any size, speed, or number of alternations.

FIG. 4.—End and Side view, Morley Transformer.

the construction adopted allows not only of a single coil of the armature being quickly removed and replaced, but a half or the whole of the armature can be easily removed. In the machine illustrated the exciting coils have a smaller diameter than the armature, and are wholly within it, and all the poles on the one side of the armature are north poles, those on the other side being south poles, the usual plan being to have these poles alternate. Mr. Morley, by his plan, reduces the E.M.F. with a given field and speed to one half, but avoids magnetic leakage and economizes copper.

By revolving the field magnet, instead of the more delicate armature, safety and steadiness of running are secured, the heavy magnet acting as an excellent fly-wheel, and effectually neutralising any pulsations due to irregularity in the stroke of the engine. This is a point of some importance where slow speed engines are used. Further, as the parts revolving at the highest velocity are simple solid iron masses of the strongest description not subject to heating, and having no copper wire to expand and fly out, the electrical and mechanical considerations which, in ordinary dynamos, usually renders low speed advisable, do

not here apply. The armature being stationary, the coils have to be supported only with a view to resisting the drag of the field. This renders insulation a matter of comparative simplicity, and is of great importance in high-tension work. The alternator is shown in its complete form in Fig. 3. The field-magnet is almost entirely hidden by sheet metal covers, which have for their object the prevention of air disturbance by the horns. The armature terminals, which are not seen in the figure, are at the upper part of the supporting ring. The thrust-bearing is adjustable longitudinally for the purpose of enabling the field to be placed exactly symmetrical with regard to the armature.

FIG. 5.—Iron Plates for Morley Transformer.

The characteristics of the machine show that it is almost self-regulating. It is, therefore, not considered necessary or desirable, except under special circumstances, to provide other than a simple hand regulation at the dynamo for the purpose of controlling the potential difference. Sudden and violent fluctuations of the lights are impossible with this machine, and an occasional touch of the resistance regulator as the load comes on or off meets all practical requirements. It is only in the case of machines whose potential curve is a rapidly falling one that it is necessary to resort to automatic control. There is no doubt that by avoiding the use of additional apparatus of this sort the chances of temporary interruption are reduced.

The total weight of the machine is 2 tons 10wt., of which just over half is made up of the armature and field-magnets.

With this machine is intended to be used the Morley transformer, shown in Fig. 4. This transformer is neatly and simply made. A suitable sized sheet of iron, S S, Fig. 5, is taken, and a rectangular piece, A B, stamped out of the centre of such a size, that the piece turned round the edges, C D, are flush with the edges of S S, and spaces are left at A and B for winding the primary and secondary coil. These coils are wound on a frame, and the transformer built up by slipping the outer iron pieces over the wire, and threading the cross pieces through.

We understand that the alternator was built directly from the designs of Mr. Morley without the necessity of experimental work to evolve the machine, thus showing that the progress made in this branch of mechanical engineering has during the past five years been very great. We design a steam-engine and build it straight away, the same, as we have said, is now being done with dynamos. Two of these machines are to be erected at the Oxford street electric lighting station.

RICHMOND UNION TRAMWAYS.

From time to time our readers have been made acquainted with the construction of the electric tramways in England, such as those of Holroyd Smith at Blackpool, and, more

recently, the Bossbrook and Newry tramway in Ireland, besides which we may mention the Brighton tramway and that at Giant's Causeway. The total mileage, however, of English tramways is comparatively small, while in America great progress has been made. The Richmond Union road, U.S., which we propose now to describe, has a length itself of about twelve miles. It runs a very irregular course through the principal parts of the city. The mileage of the streets passed through is about nine miles. The central section is a double line for a distance of about two miles, a part being laid on paved streets and the remaining on macadam. In our last issue we dealt with the differences of tractive power required on gradients and curves. Part of this line has sharp curves and steep gradients. In one portion the rails are laid in four curves of respectively 27, 30, 40, and 50ft. radius. Altogether, there are no less than twenty-nine curves, requiring bent rails, the majority being of sharp radius, five being less than 30ft.

There is one section of almost continual ascent for about 5,600ft., with gradients varying from 3 to 7 per cent., and another stretch of 1,900ft., with gradients varying from 3 to 10 per cent. The experience of our American contemporaries is, that it is far cheaper to construct a good line at the first rather than to construct a cheaper line. Among other suggestions, all curves should be bound in and paved. They should likewise have two guard rails, because it is much easier to steer a car by its rear wheels, by holding them in place, than by allowing them to crowd the inner rail, and force the forward wheel to climb the outer one. In dry weather it is found advisable to grease the grooved rails. Another point which is to be carefully considered is the character of switch used for sidings and cross-overs. If drop switches are used, they should be of such character as to allow the car to come down easily. This line has been fitted up by the Sprague Electric Motor Company. The generating station is at about equal distance from the extremities of the line. The station includes three brick buildings, the main building containing the engines and dynamos, being separated from the other two by a covered way. The cars are kept in one of the other buildings, and the third is the boiler room. The latter contains a battery of three cylindrical return tubular boilers of the latest pattern, mounted on a Jarvis patent furnace, their capacity being 125 h.p. each.

Water is furnished by two Worthington steam pumps. From the pumps the water passes through a feed-water-heater, where it is heated from 150deg. to 200deg. Fahrenheit, after which it goes through a filter. The boilers feed into one main-feed steam-pipe, which in turn leads to a separator, a large iron cylinder into which the steam passes, the water falling to the bottom, and the dry steam being carried off at the top. From the boiler-room, both the steam and exhaust pipes run into an underground trench to the engine-room. This trench is of brick, the walls and bottom being 8in. thick, and after the pipes were put in place they were completely covered in with mineral wool, and the trenches covered with planking. The engines, of which there are three, are of the Armington-Sims high-speed type, and develop, when running at full load, 125 h.p. Each engine drives two Edison dynamos, of 40,000 watts capacity each, specially wound for 500 volts normal pressure. The dynamos feed into copper bars, supported on the walls by porcelain insulators.

Each dynamo has its independent ammeter, and in addition there is a general ammeter at the end of the positive bus bar. From this bar the current passes to four special snap switches, each switch being connected, through a three-plug safety switch block, to one of the feeders supplying current to the main line wire. These four feeder wires tap into the line wire at four different points, thus maintaining the pressure approximately equal all along the line. At the ends of one of the feeders in the central station, pressure indicators are to be attached which will indicate the voltage at the junction of the feeders with the main current wire.

The engine room is brilliantly lighted by eight hanging electrolights, each of which has five incandescent lamps. A switch board at one end of the room furnishes an independent control for each group of lamps. All wires in the room are well insulated, and in addition are held off from

the walls and ceilings by porcelain insulators. The engines and dynamos are fenced in by polished brass railings, brass oil screens and drop cups are placed wherever necessary; on the floors are brass-tipped matings; and, in fact, the room is kept as neat and clean as a well-appointed office, and it is not going too far to state that the station equipment has no superior in the world.

The electric circuit consists of two parts—the overhead and the ground circuits, each being of compound character. Along the kerb stones, at distances of 125 ft. are 30 ft. poles, inserted into the ground a distance of 5 ft. Great difficulty was experienced at first on account of the clayey character of the soil, and it became necessary at the corners to put in very heavy poles, which were embedded in concrete and stone, to prevent settling out of place after heavy rains. These poles carry the main circuit, which extends throughout the entire length of the road, and is a copper wire $\frac{1}{2}$ in. in diameter. This is called the main conductor, for on it depends the operation of the road in case of accident or repairs to the contact wire.

This latter is termed the "working conductor," and is of hard drawn copper of the same size as the main conductor, and is carried over the centre of the track, at a distance of about eighteen feet from the ground, on insulators supported by span-wires running across from pole to pole, and provided with additional insulators at their ends. The whole structure is very light looking, and at night cannot be seen. It hardly seems possible that it can be the medium of transmission of nearly 400 h.p. of electrical energy distributed over twelve miles of track, on which at any one time forty cars can be in operation. This working conductor is of the same size no matter whether one or a hundred cars are to be operated, or whether one or twenty miles of track are to be covered, but it is connected to the main conductor at intervals of 500 feet by short branch wires, the whole forming a ladder like circuit.

This main conductor is itself supplied at four widely separated points by feeders which come from the main supply at the central station. Without the use of these feeders, which can also be reinforced if necessary, the size and cost of the overhead conductors would be very largely increased. The curves are formed of a series of short chords, which approximate the central line of curvature.

The current is taken from this working conductor by a light ornamental structure on top of the car. This consists of a low skeleton framework, which carries an adjustable swivelling trunnion, having at its upper end a jaw in which is suspended a counter balanced trolley pole, having at its extension a grooved wheel making running flexible contact on the under side of the working conductor. The flexibility of this arrangement is very great, it being able to follow with perfect facility variations of the trolley wire 2 ft. or 3 ft. in either horizontal or vertical direction at any speed and around any curve. When getting at the end of the track, this trolley trunnion is swung around so as to trend in a proper direction abait the centre of the car. It is impossible for it to pull the trolley wire down, and if off the line can be replaced from the car quickly and easily in the darkest night. From the trolley the current passes through a protected wire to two switches, one at each end of the car, whence, after whatever commutation is necessary, it goes to the motor circuits, and thence to the wheel frame.

The return circuit is through the track, and thence by both metallic and ground circuits to the station. Each section of rail is joined to a copper ground wire, which runs throughout the length of the road underneath or alongside the stringer-pieces. At intervals of 500 feet this ground wire is connected to an earth plate, and at seven points widely distributed. These ground plates are supplemented by heavy iron pipes sunk into iron ore or 12 in. water wells about 25 feet deep. The ground wire is connected to the station, and there is also a main ground connection made there in a thirty-foot well through a large sink plate. Some modifications of the overhead system are now being made which will make it impossible for any accident to one section of the line to disable the remainder; will enable the different sections to be operated independently, and, in case of a fire which may necessitate the blocking or temporary disabling of one part of the line,

will allow this section of the line to be cut out of action either automatically or at will.

Each car is fitted with a duplicate and very powerful motor equipment. This is carried entirely beneath the car body, is very compact, out of sight, and necessitates no radical change in the construction of the car. The body had to be stiffened a little, and 3 in. steel axles put in. One of the great objections which has been met with in applying motors, whether steam, electrical, or of any other character, to the propulsion of street railways, has been the difficulty of getting sufficient track adhesion to operate the car under all conditions of track, loads and grades. Especially was this objection true in Richmond, where it was manifest that no application of a motor system could be fully successful unless the entire weight of the car and its contents was made available for traction.

One of the manifest reasons is, of course, the slippery character of the track under many conditions. Another thing should also be noted, and that is that it is almost impossible in practice to cast all wheels exactly the same circumference, or at least so that the path described by the line of contact shall be the same for all wheels. Moreover, on curves the wheels are all travelling over paths of different lengths. Theoretically, the wheels should be independently driven, but since this is not possible it follows that the next best thing is to drive each pair of wheels independently. It is a fact which admits of no dispute that there are conditions of track which will not admit of a car being driven from one pair of wheels only, and this difficulty is often augmented by the fact that if one pair of wheels only is used they will sometimes be leading, sometimes following; on heavy grades, too, with one platform reserved for the driver, there is a very serious displacement of the centre of gravity, and there may be very much more weight upon one pair of wheels than on the other. The whole experience in Richmond has been to emphasise the value of independently driven axles.

To accomplish this, each motor is centred upon its axle; and to allow the required freedom, and at the same time to preserve perfect parallelism in the meshing of the gears, and also for taking part of the motor off the body of the axle and to throw it on to the journals, one end of the motor is supported near the centre of the car by double compression springs playing upon a loosely suspended bolt which is supported from a cross girder in the bottom of the car.

The motors are then, so to speak, weighed or flexibly supported from the car body, and the motion of the armature is transmitted to the axles through a novel method of spring gearing, of compact form and great strength, so that whenever the axles are in motion there is a spring touch of the pinions upon the gears. Barring friction, a single pound pressure exerted in either direction would lift or depress the motor a slight amount, and no matter how sudden the strain, whether because of a variation of load or speed, or a reversal of direction or rotation, it is impossible to strip the gears unless the ultimate strain exceeds the strength of the iron, the pressure on the gears always being a progressive one. The motor armature makes nearly 12 revolutions to each revolution of the car axle, but by an ingenious automatic lock switch an electrical mechanical gearing can be effected with double the torsional effort for a given current and cuts down the speed.

The motors, although in one sense independent, are connected with duplicate switches at either end of the car, which afford simultaneous control of both machines. These motors, which are of normal capacity of $7\frac{1}{2}$ h.p. each, can for a short time work up to 25 h.p., and are capable of producing a momentary tractive effort of over 3,000 lb.

The cars can be run at widely different speeds, varying from the slowest crawl to twelve or more miles per hour. They can be started and stopped without the use of brakes in the space of three or four inches, and when making the normal running speed can, in an emergency, be stopped and reversed without brakes within less than a quarter of a car-length. The control over the car seems marvellous, for one sees little or nothing save an almost imperceptible movement of the hand of the motor-man; and the starting, although prompt, is gradual, and without shock or jar.

Emergencies sometimes bring out qualities of motors

which are unexpected, or which, at least, if counted on, are rarely ever brought into play. On one occasion a man was descending a 6 per cent. grade with a heavy load, when his brake chain parted. Seeing a sharp curve right ahead of him, which he knew he would leave if he struck it at the speed he was running, he instantly reversed his machines and brought his car to a standstill, and on the rest of his trip handled his machines entirely with the motors. On another occasion a man passing from behind one car directly in front of another, was struck and knocked down by the dashboard. Although the car was moving at a lively gait, the machines were reversed, and the wheels stopped within a foot of the man. By any other method of propulsion he would have been killed. Frequently, on a 10 per cent. grade, with a loaded car, the brakes have been thrown off, the machines reversed, the car stopped, and started backward up-hill within less than one half of its length—a test of the most remarkable severity.

In noting the wonderful control of the car, one is struck at the remarkable character of the traction, and cannot help wondering where it comes from. Unquestionably, it is in a large measure due to the fact that every pound of weight is available for traction, and that the two wheels, being independently driven, can take their own speed, and each pair get the best grip.

Another thing to be noted, where the ground circuit is used, is the increase of traction due to the passage of the current from the wheels into the rails. Exactly what molecular action takes place has not been ascertained. It may be simply heating at the contact surface; but the fact remains that the traction is very largely increased. The magnetic condition of the wheels and tracks also has some function in this increase of traction. The wheels and axles are magnetised by the method of motor construction and mounting, and also by the passage of the current through them. The trucks are likewise magnetised by the current passing through them, and also by the rolling contact of the wheels. Yet, admitting all these aids, the results have been extraordinary.

Sixteen foot closed cars carrying picked loads of fifty five to sixty passengers, and having a total weight of 15,000 lb., are operated on the 10 per cent. grade, often with a slippery and slimy rail, and on 27 ft. curves, without the use of sand or extra help.

These same grades and curves have been ascended also without sand after one of the worst sleet storms that has visited this section for years. Various tests under the most unfavourable conditions have been made, cars often being required to cut their way through clay, snow, and ice when the tracks were out of sight. No severer test could have been made, and the power and tractive effort developed have exceeded the most sanguine expectations. Cars have often been stopped and started on the heaviest grades, and in the sharpest curves. One motor has propelled two cars around sharp curves and up 6 per cent. grades. One car has pushed another of greater weight around the sharpest curves and up 7 and 8 per cent. grades, both straight and combined.

During the three and a-half months' operation, although there have been troubles, and changes have been made while the cars are running commercially, no car has been pulled a foot by animal power; if any accident has occurred to a motor the car has gone along with one machine, oftentimes with heavy loads and on heavy grades, or in some cases has gone home in company with another car. One hundred and twenty men who did not know the difference between a motor and a handsaw have been broken into handling these cars; oftentimes with remarkably short training. In fact, more than 120, because a number had been dismissed for various reasons.

Some things peculiar to the electric car may here be mentioned.

A marked advantage of it in a crowded street, in addition to the power of control, is the fact that all the horse room is saved, and the car consequently is able to be worked with much narrower limits.

Where grade work is encountered, an electric car can not only make double the speed on the up grades, but can run on down grades at a much higher safe rate of speed than horses can be driven ahead of a car.

A car has none of the lurching motion which is experienced in cable transmission, and is so marked on the Philadelphia road, and it has in a marked degree less of the oscillation caused by the pull of the horses on the draw-bar.

The layer of mud of which the dash boards of a street car is decorated from the hoofs of the horses is, it is almost needless to say, absent on an electric car.

The lighting, for which each car with its five lights require about half a horse power, is very brilliant, and free from the odour attending the use of oil.

The figures which follow, being based upon an actual service increasing from eight to thirty cars, and extending over a period of four months, under the most trying circumstances and at the most critical and care-requiring period of the enterprise's existence, give street railway men the most careful and liberal estimate of every possible expense attending the operation of the road which is any way dependent upon its electrical features. The operating expenses are given under two heads; first, the central station operating expenses, and second, the road operating expenses, the two constituting the total cost of motive power. These are given in detail, and they will probably be found to cover every expense, although in some small ways the distribution of these expenses may be found to be changed by several months longer running. The fuel and other incidental expenses of the station are from the engineers' record, and checked by the readings of the electrical instruments.

The central station expenses are as follows:

58 ½ cwt. coal at 10 cents	\$5 81
113 ½ cwt. screenings at 7 cents	7 96
5 pints cylinder oil at 75 cents per gallon	.47
5 pints dynamo oil at 30 cents per gallon	.18
31b waste at 10 cents	.30
Water at current rates	3.00
Fuel, &c.	\$17.75
1 day engineer	\$3.00
1 night engineer	2 25
4 firemen	6.00
1 cleaner	1.50
2 dynamo men	3.50
1 electrician	4.00
Labour	\$30 25
Lighting	.50
Depreciation: on dynamos 3 per cent., and repairs	1 50
On engine boilers 10 per cent.	4.39
Total central station expenses	\$44.03
or \$1.48 per car making 80 miles.	

In estimating the road expenses, more than liberal allowance is made; but in a new enterprise it is safe to err on this side, rather than attempt to claim for a system advantages which will not in practice be borne out. The expenses are then as follows:—

Oil, grease and waste	\$1 50
Brushes	4 00
Trolleys	2.40
Material	\$7.50
3 mechanics and one helper for thoroughly overhauling motors once a week, making repairs, adjusting brakes, &c.	7 00
4 inspectors, two days and two nights, for oiling machines, and looking after brushes	7.50
2 night inspectors to thoroughly inspect motors after cars are laid up and see that all bolts, nuts, and connections are tight and that everything is in good working order for the morning run	4.00
1 welder and helper for making any repairs which may be necessary and any testing which is required	3.50
2 firemen	6 00
1 carpenter to fix windows, sashes, switches, signs, &c.	2.00
Labour	\$29.90
Depreciation { on car work at 15 per cent.	10 00
{ on line work at 10 per cent.	1 00
Depreciation	\$22 00
Total road operating expenses	\$59.40
or \$1.98 per car making 80 miles.	

The total motive power expenses both in the central station and out on the road would not then exceed \$3.46 per car, making eighty miles, or 4 ½ cents per car mile, and this includes everything except the executive and salary

expenses, taxes and insurance, and is only 50 per cent. of the cost of operation by horses with the same number of cars.

But the showing is even better than this, for another fact is to be noticed, and it is an important one from an economical point of view. Twenty cars on duty for about eighteen hours make a mileage of from 1,500 to 1,800 per day, and if it were not for the fact that the schedule requires them to operate part of the time on a single track with insufficient turnouts, they could make 1,800 or 1,900 steadily, this notwithstanding the fact that the speed is limited by regulations. Many of the cars often run over 100 miles. This same mileage and intervals made by twenty electric cars could not under the circumstances be made by anything less than twenty five horse cars of the same size, and the electric cars probably carry in the aggregate just as many passengers. It follows, that to get the same service with horses, not only would the number of cars have to be increased, but likewise the number of horses, conductors, and drivers. The same mileage performed by horses with these cars and grades would require a stable equipment of not less than 275 to 300 horses.

A good idea of the operation of the system may be obtained from the following weekly table taken from the records of the railway company:

Week ending	No. of cars put out for regular service.	Average number of cars out per day.	Miles per week.	Average miles per day.	Average miles per car per day.	Passengers per week.	Average passengers per car per day.

UNDERGROUND ELECTRICAL CONDUCTORS IN EUROPE AND AMERICA.*

BY PROF. G. W. PLYMPTON.

The problems of construction of underground systems of electrical conduction will have been solved when the telephone and the arc light systems are both buried under our streets without impairing the efficiency or durability of either.

By this I mean that all the difficulties encountered in burying conductors are involved in converting telephone and arc light from aerial to underground systems. Telegraph lines and systems of incandescent lighting present fewer difficulties in the process of burying, and none of a kind not met with in dealing with the systems first mentioned.

The telephone problem is substantially solved. Some details only remain to be settled, among which may be mentioned the best size of conductor, the most serviceable insulation and the maximum distance of effective service for either grounded or metallic circuits.

In Brooklyn the general plan adopted is that of a conduit divided into ducts through which cables containing from sixty to one hundred wires are drawn. The material of the conduit is for the most part creosoted wood. About ten miles of this is already in use in our city, and about four and a-half miles of the Dorset concrete conduit. For the extensions of the underground systems for the present year only creosoted timber is to be used.

Among the lessons learned from our experience are:—1.

* Read before the American Institute of Electrical Engineers, May 16, 1888.

That in creosoted conduits the use of cables covered with kerite, or any similar rubber or gutta-percha compound, must be avoided. 2. That in the so-called lead covered cables the use of pure lead is also to be avoided, as it is slowly converted into a porous and friable lead carbonate. An alloy of lead with 5 or 6 per cent. of tin seems to resist the destructive action. 3. That the conducting wire first used is too small for satisfactory telephone service. The difficulties of induction and retardation led to complaints as soon as 1,000ft. or 5,000ft. of underground wire was put in service. The cables that are now being put in are made up of wires whose cross section is greater by one third than that of the first wire, and they are protected by twice the thickness of insulation.

I mention the above conclusions as having been drawn from our own experience in Brooklyn.

In commencing our work, we gathered such information as could be gleaned from localities where solutions of the problem had already been attempted. The impression so largely prevailed that in Europe all telephone and telegraph conductors were underground, that our Board decided that a personal inspection of European systems should be made by one of our number. The duty devolved upon me. The result of my inquiry has been published in the scientific papers.

I will briefly refer to a few of the incidents. (Prof. Plympton here gave an epitome of the third annual report of Brooklyn Subway Commission, which embodied his observations).

In regard to the burial of the arc light wires, I can only say that no method yet tried seems certain of success. Most of them certainly insure the destruction of the underground conductors in from one to three years. But I have no doubt that a solution of the problem will soon be reached, although the system will be kept apart from the telephone and telegraph subway.

It does not seem likely that arc light conductors will be allowed in the same conduit with telephone wires, nor will they be distributed from the same manholes.

In saying that, I believe that a solution of the problem will soon be found. I do not mean to assert that casualties like that recently recorded of a man in the Bowery, who lost his life by grasping the naked wire close to an arc lamp, can be prevented by any system of burying wires. To prevent such accidents—if that is the term to be used—the arc lights must be buried with the wires.

All past experience teaches us to proceed cautiously. Nothing can now permanently check the growth of the telephone, the telegraph, or the electric light. They have become necessities of our civilisation, and any hasty or ill-advised enforcement of the law to convert all aerial to underground systems which should result in serious injury to them, would prove the surest way to perpetuate the nuisances of overhead wires and poles in the streets.

CORRESPONDENCE.

THUNDERSTORMS AND LIGHTNING ACCIDENTS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—As the season of thunderstorms and lightning accidents is now approaching, I hope you will kindly allow me to make known through your columns the fact that in the interest of science the Institute of Medical Electricity is very desirous of obtaining authentic information concerning lightning accidents, whether fatal or otherwise. I should, therefore, esteem it a favour if some of the many friends of humanity among your readers will assist us to investigate these phenomena by sending me such particulars of accidents of this nature, as they may have personal or reliable knowledge of, as soon after they occur as possible.

Of course, electrical and physiological details are what we most require, but reliable general information is often very valuable, and will be gratefully received.—Yours, &c.,

H. NEWMAN LAWRENCE, A.S.T.E. and E.,

Electrician to the Institute of Medical Electricity,
24, Regent-street, London, S.W.

THE ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. *Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

THE BRIGHTON ELECTRIC RAILWAY.

Was it not Whewell who first wrote about the martyrs of science? Probably, however, there is a class of men fated to suffer more from their fellow-men than those who are pioneers of pure science, and this is the pioneers of applied science. Archimedes fell under the sword of a common soldier: Galileo fell into the hands of the Inquisition. The former lost his life; the latter quibbled, and saved it. In these latter days it is not the life of a pioneer which is at stake; it is his money. The uneducated mob attempted the ruin of Arkwright. We had almost added that an educated mob has ruined a pioneer of electrical engineering. Many readers of the *Telegraph* interested in electrical progress were no doubt astonished to read the other day that another attempt was to be made to do away with the Brighton electric railway. A special meeting of the Town Council was convened for last Wednesday to consider a recommendation of the Works Committee that the proprietor of the electric railway should be required to remove his plant. It is quite time someone indulged in a little plain speaking on this and cognate subjects. A good deal of opposition has been encountered by electric light contractors to the erection of machine rooms, because of the noise of running machinery. There is some reason for this, and dwellers in private houses may not be blamed for describing a nuisance by its proper name, and demanding that every effort should be made to reduce the noise to a minimum. The continued opposition at Brighton is not of this kind—it has no legitimate origin, and proceeds from those whose real object is hidden. Many of our readers do not know Brighton, but they may know that it is almost a suburb of London—a suburb by the sea. Of late years a large number of wealthy people luxuriate in a house at Brighton, and would reserve the whole place to themselves. They hate excursion trains and excursionists as the proverbial devil hates holy water. They would make Brighton a second Belgrave-square, where corduroy should be unknown, and no one permitted to visit who did not put on a dress suit for dinner. Hence anything that tends to popularise the place and attract visitors is an eyesore to those whose aim is exclusiveness. We do know Brighton, and maintain that we are as well able to judge of the allegations made against the electric railway as the *Daily Telegraph*. The *Telegraph* tells us that "the ground is wanted for the new works on the Madeira-road." We say distinctly it is not so, and that the contemplated improvements are not on the ground of the railway at all. The Madeira-road is a *cul-de-sac*, and never will be an aristocratic resort, like the Hove end of the Promenade. The sea wall, from thirty to fifty feet high, bounds one side of the road, on the other is the shingle, and along the edge of

the shingle the electric railway runs. The only interference the railway has committed is the removal of a few capstans half-a-dozen yards. The ordinary roadway has been improved, by being widened and levelled. The fact is that the opponents of the railroad think any stick good enough to beat a dog with. They have been consistent; and though for a while the supporters of the railway were the stronger, the strain has been too continuous, and the supporters are disheartened. Years ago, when "electricity" was the "coming wonder," Mr. Volk, of Brighton, a well-known electrician, had the idea that electricity was applicable as a motive power, and he obtained permission to make this experimental railway. It was the first in England, almost the first in Europe. Electricity was the unknown force then with which the world was to be revolutionised. The few did not want the revolution, and preferred to remain "as you were." Notwithstanding the opposition, the line was laid and operated successfully. Mr. Volk was a working electrician, believing in his work, and not only laboured, but put his whole savings into the line. It was successful, and everything promised fair. Nature, however, in the shape of storms, shattered the line and did hundreds of pounds worth of damage. The opposition, too, had not been idle, but persistently attacked the line at every opportunity; instituted legal proceedings, and ultimately the losses, one way and another, brought the owner into the bankruptcy court. Some friends made strenuous efforts to counteract the opposition, but in the end, from all we hear, the result will inevitably be the destruction of the Brighton line. For the moment, however, a respite has been given, the result of the special meeting of the Town Council being that it is not deemed expedient to reopen the question of the removal of the railway until the improvements on the Madeira-road lately sanctioned are completed. It might be explained also that the residences above the Madeira-road are wholly out of sight of the railway, so that it forms no bad feature in the land, or rather seascape, as seen from drawing-room windows. The machinery, too, is in what may be termed a cave excavated in the hill side, so that it creates no nuisance.

Such, briefly, is the history of the first electric railway in England. Promoted and constructed by the energy of one man, satisfactorily worked against all difficulties brought forward by pride, prejudice, and ignorance, it remains in the unsatisfactory condition we have described. Is it too much to hope that the supporters of the railway will not hesitate to continue their efforts, and obtain some arrangement whereby the founders of this line may be relieved from the worries and anxieties of these constant attacks? It is admitted that the line has been and is an attraction to the eastern end of the

town, and we contend that whatever proves an attraction to the town is beneficial to the business portion of the town, and this is far more important than that a few moneyed men should have the exclusive right to a mile of beach and a sheltered promenade.

ALTERNATE-CURRENT MOTORS.

Some weeks ago, quoting from a New York contemporary, we were able to direct attention to M. Nikola Tesla's work in connection with the use of alternate currents and motors. At the late meeting of the American Institute of Electrical Engineers, M. Tesla read a paper upon the subject, amply illustrated and descriptive of the work upon which he has been engaged. It is too soon and the materials at command are too scanty to enable a definite conclusion to be arrived at, but whatever further information may bring forth, there is no mistaking the fact that this paper will mark an era in the progress of electrical engineering. The thoughts of many inventors have been directed to the design of alternate current motors, practical men have pointed out the link wanted in the apparatus supplied them, and the supporters of the continuous current system have had their hands considerably strengthened from the fact that no apparatus was discovered whereby energy could be distributed by means of alternate current machines. The advocates of alternate currents pointed out that could such apparatus be devised it would probably lead to a reduction in prices for machines, and decrease the cost of maintenance and the probability of breakdowns. M. Tesla's work, be it crude and impracticable, or fairly perfect and practical, will enforce the dictum that a want has only to be felt, and sooner or later it will be supplied. We have never aided with those who professed such apparatus to be impossible. The greater number of mechanical and continuously rotary movements are obtained by the application of opposite forces at different periods. The maidservant draws a pail of water from the bottom of a well by alternately pushing and pulling on the handle of the windlass. The locomotive goes continuously forward, by reason of the expansive force of steam applied first in one direction then in the opposite direction, and it was doing an injustice to the inventive talent of the world to believe that the push and pull of electricity could not be used to obtain continuous motion in any desired direction. The views expressed by M. Tesla in his paper will be carefully studied, and, without doubt, there will follow many improvements in the direction he has pointed out.

How SCIENCE ADVANCES.—"He who wishes to keep abreast with the march of science to-day, must leave the college and go to the workshop, and into the dark corners of private laboratories, for investigators rarely have time to write, so that text-books are years behind the science itself."—Prof. Elisha Gray.

THE COPPER ACCUMULATOR.

Messrs. Commelin, Desmazières, and Baillehache have been engaged for some considerable time upon the construction of a new type of accumulator which has attracted a large amount of attention. The Commelin accumulator is based upon a peculiar property of metals hitherto little heeded.

If a metallic powder is compressed under a pressure of 500 or 1,000 atmospheres, a metal is obtained of a perfectly solid and homogeneous nature, but porous. Externorily, it presents the characteristics of cast metals, and differs only in being considerably lower in density, and in this state the new metal absorbs nascent oxygen with extraordinary facility. The zinc-copper potass element designed by Faraday polarises after it has been a short time at work; it is able to give a constant current only for a short period, owing to the small quantity of oxide with which the ordinary sheet copper of commerce is covered. When this element is exhausted—that is to say, when the potass is saturated with zinc—the Faraday cell consists of zinc, copper, and zincate of potass. In attempting to regenerate or renew it by electrolysis, some of the zinc is precipitated on the remaining zinc, and oxygen is carried to the copper plate, which is oxidised superficially. But the oxide of copper formed under these conditions, being soluble in the potass, copper will be precipitated on the positive element at the same time as the zinc, and will cause local currents, so that the regenerated cell will give only very moderate results.

The substitution of a plate of porous copper for the copper plate of the exhausted Faraday cell, will give an element whose regeneration can be effected in a slightly more satisfactory manner. The copper is dissolved less quickly in the potass, and is deposited less rapidly on the positive zinc, but still the final result is not much better. If, however, the porous copper is covered with parchment paper, the regeneration is effected without difficulty; all the dissolved zinc is deposited, the porous copper absorbs an equivalent quantity of oxygen, and an apparatus is obtained which can be indefinitely regenerated. This is the principle of the Commelin copper accumulator.

For negative electrodes in charging, it has plates of tinned sheet iron, and for positive electrodes plates of pure porous copper, obtained by compression, at 500 to 1,000 atmospheres, from powdered copper obtained by electrolysis. The positive electrodes, enveloped in parchment paper, are separated from the negatives by tubes of glass, or preferably by strips of vulcanite, and the whole is immersed in a box of white metal containing zincate of potass or soda, according to the application. A battery of these accumulators has been constructed to furnish the motive power for a screw launch for the French Navy at Havre.

The accumulator used in these experiments contained six negative electrodes and five positive. Their usual height is 56 centimetres (22in.), their width 12.5 cm. (5in.). The total surface of the positives is 70 square centimetres. The white metal box is 70 centimetres high (27.5in.), 15 centimetres (5.5in.) wide, and 8 centimetres (3.1in.) deep. The quantity of zincate of potass is 6 litres (1½ gallons) per cell, and the weight is 18 kilos. (14lb.).

The zincate of potash in the marine type contains 150 grammes of zinc per litre, which is 900 grammes for 6 litres. This corresponds to a capacity of 733 ampere-hours, when all the zinc is precipitated. When the cell is newly mounted, the porous copper plates, which remain exposed to the air for a certain time, become oxidised, and, if charged under these conditions, the action is unsatisfactory. It is indispensable, in order to put them in a good state for use, to submit them at first to a reducing current—i.e., only in a contrary direction to the charging current.

During the operation of charging, the zinc is deposited on the tin plates, and the oxygen is carried to the porous plate without the least development of gas. The oxygen, arriving at the positive, combines with the copper, or possibly is only occluded. If it combined with the copper, it would only be able to give a sub-oxide. As a matter of fact, the cells being charged, if the positives are removed their aspect is soon to be unaltered, and have kept their original red colour, which fully indicates that they

do not contain cupric-oxide, which is black. Even admitting the formation of cupric-oxide during the charge, this compound, being soluble in potass (3), the solution being in intimate contact by reason of the parchment covering with an excess of metallic copper, will be restored to the state of protoxide: $\text{CuO} + \text{Cu} = \text{Cu}_2\text{O}$. Moreover, this reaction must always be produced, for the porous plates of the marine type can only receive 800 to 900 ampere hours, that is to say, one-third of that which they could receive if the copper was transformed into cupric-oxide. There is, therefore, always at the positive an excess of metallic copper; therefore an absolute impossibility of the formation of cupric-oxide.

Some curious phenomena are observed when charging this accumulator. At the beginning the level of the liquid rises, and continues to rise progressively until the moment of stopping the charging. When, on the contrary, the cell is discharged, the opposite phenomena occur: the level of the liquid gradually falls, and does not return to its original point until the accumulator is entirely discharged. These facts seem to prove that the oxygen must really be occluded. If it combined with the copper, the rise of the liquid would not take place at first—the level would not be raised until after the copper were combined. Then only the oxygen filling the pores of the plate would increase the volume of the liquid. At the discharge, on the contrary, the oxygen ought to disappear immediately, and the liquid regain its normal height some minutes after closing the circuit. It is found that this does not take place until the cell is entirely discharged.

The rate of charge of the marine type of cell is about 30 to 35 amperes, with a maximum electromotive force of 1.2 volts, time about twenty-four to thirty hours. The rate of discharge in the trials with the electric launch was 80 to 90 amperes, with a difference of potential of 0.75 to 0.80 volts. According to the recent experiments made by M. Krebs with a motor driven by this battery, an efficiency is obtained for quantity of 86.5 per cent., and of energy of 65 per cent. A rate of charge of 100 amperes has been used. It is a matter of important progress to notice that the duration of charging will be considerably shortened. It can be thus charged in seven or eight hours.

It should be mentioned that M. de Lalande has laid claim to priority for this invention. M. Lalande reminds us that he also has a copper battery, which is reversible, and equally renewable by electrolysis. A specification of this character has indeed been included in M. Lalande's patent. But to this the inventors object that M. Lalande's battery is derived from that of Faraday, and in the same manner as that type, is not able to be renewed by electrolysis, because in charging cupric-oxide is formed, which is soluble in potass (1), and therefore there is precipitation of copper upon the negative. In addition, the renewal cannot be practicable with electrolysis, because the authors propose the following proceeding at the beginning, the zincate of potass taken from the elements is treated with sulphuretted hydrogen, which gives a sulphate of zinc useful for paints, the reduced copper is exposed to the air to be retransformed to cupric-oxide. Though it may be stated that a battery is theoretically renewable by electrolysis, there does not exist one in which this is practicable. In the battery, the chemical reaction which produces the current is prepared by the chemist, and it is quite ready to act at the moment the circuit is closed. In the accumulator, on the other hand, this reaction is prepared by a current, and, up to the present, it is only possible to renew the reactions produced by the current itself.—*Electricité*.

[NOTE. We have ventured to query the statement, made in two places by our contemporary, in investigating the theory of this accumulator, that cupric-oxide is soluble in potass. ED. E. E.]

RIGGS' ENGINE.

In our issue of May 18th we described the "Mather" dynamo, which is based upon the revolving engine of Mr. A. Riggs. That this is the case will be seen from the accompanying illustration and description of this engine, which is intended to be a combination of the most recent improve-

ments directed towards accurate driving and the utmost economy in fuel. It is the outcome of the inventor's experience gained, since 1872, with engines of the usual reciprocating type running at high speeds, and its arrangements have been perfected after a critical examination of the most successful modern engines in England and America made during the autumn of 1884, after the visit of the British Association to Montreal.

This invention initiates a system of construction free altogether from reciprocations, which are inseparable from all other engines having pistons and cylinders; it also provides the means of running without any irregular dynamical strains. In slow-moving engines the power absorbed for accelerating their reciprocating parts is considered to bear but a small proportion to the total amount, so that early rates of expansion can be used with a low average pressure; but this is not the case with quick-running engines, where the power required for acceleration may reach 20 per cent. or more of the total work done, unless a high average pressure be maintained. It is mainly from this cause that high-speed engines, as at present constructed,

which, while removing all the evils of reciprocation, possesses none of those objections which have caused the practical failure of other attempts in the same direction. The illustration and diagram show that this engine consists of four cylinders, all revolving freely and independently upon a common central stud. Their pistons are all connected to corresponding crank pins, equidistant apart on the face of a wheel, which also turns freely round, and no other connection exists as between cylinders and pistons except that already mentioned. The centres of cylinders and wheels are parallel to each other, but yet at a certain distance apart, and thus, while both revolve together, the pistons, which are carried by the wheel, are seen to reciprocate in relation to the cylinders, although both are partaking of a simple independent revolution. This relative movement answers exactly the same purpose as the reciprocation of an ordinary piston, only that as the cylinders are truly balanced among themselves, and the pistons are balanced each to each, a perfect balance is maintained throughout the revolutions. The cylinders are weighed against each other during construction, and so also are the pistons; therefore the machinery

Rigg's Patent Revolving Engine.

do not employ an early cut-off, nor produce those economical results which are commonly found with larger engines of equal power. The assumption that power taken up during the first half of a stroke can be recovered towards its conclusion assumes that there is something to be gained by compression of exhaust to fill capacious passages; whereas this operation is but an expedient for receiving the impact of a steam hammer, which would produce a violent concussion if permitted to expend its full force upon the crank pin.*

Having investigated these problems with much care, and having enjoyed opportunities of putting high speed theories into practice, the conclusion was reached that those evils were inherent in all existing engines, and that no real remedy could be found so long as reciprocation of the piston formed an essential feature in their design.

This conclusion revealed new difficulties, but it led finally to the invention of the revolving engine in a new form,

* The influence of reciprocation, and the limits beyond which high-speed engines should not be driven, are fully discussed in Mr. Rigg's "Practical Treatise on the Steam Engine," 1878, and in his paper on "Obscure Influences of Reciprocation in High Speed Engines," published in the *Transactions of the Society of Engineers* for 1886. See *The Engineer* of 4th June, 1886.

runs in true equilibrium with a dynamic balance that is practically perfect, and there are no reciprocations; and, as a proof of the correctness of these deductions, these engines have been driven over 2,000 revolutions per minute without any vibration, producing only a loud hum by so high a velocity. They run quite quietly at more reasonable speeds, and with careful adjustment are practically silent. Referring again to the design of the engine, it is easy to see that admission of pressure while the pistons move out, and opening of exhaust during their return, causes a revolution to take place; and, as there are four cylinders, no dead centres exist, and the engine will start itself perfectly well from whatever position it may have come to rest. It follows that there is a tangential driving effect of great uniformity, and no maximum with recurrent absolute zero, such as happens with single cylinder engines of ordinary types. Even under so sensitive a test as driving a dynamo, it is found that incandescent light can be obtained of an absolute steadiness without any fly-wheel beyond the engine itself, and there is no other motor that can compare with these results except a turbine.

Such angular changes in velocity as do occur in this

engine balance each other exactly, because power absorbed in accelerating one cylinder while moving from 3 to 1 is being restored at the same time by the retardation of another cylinder moving from 1 to 3, and thus a complete cycle of equilibrium is established, and as no dynamic strains interfere with the regularity of driving, its smoothness excels that of reciprocating engines as usually constructed.

The cylinders are enclosed in a bed with removable cover, so that all vital parts are protected, and lubrication facilitated. In the engraving the cover is removed.

Four separate steam ports are provided, and are presented in turn before a fixed inlet and exhaust, so that steam enters each cylinder to force the piston out, and passes away during its retreat, and there is a constant driving power, so the engine will start from any position. Regulation as to speed is accomplished by a powerful and sensitive governor enclosed within the main driving pulley, and its movements are conveyed by levers and rods to a balanced expansion valve, which causes no change in the exhaust, however the point where steam is cut off may vary. This expansion valve is arranged to cover or uncover a number of small steam ports set in one angular direction around the fixed valve face, so that more or less steam is admitted as required, and the rate of expansion varied accordingly.

Bagg's Engine—Section.

These revolving engines are conveniently compounded by placing two simple engines on opposite ends of the same shaft, and under all conditions experience shows them to be as durable and working with economy in fuel equal to the best larger engines of corresponding power.

For marine or winding engines the valve setting has the peculiarity that either ahead or astern the exhaust remains unaltered, while the rate of expansion is caused to vary; and rods or handles to move the valve for starting, stopping, or regulating the expansion ahead or astern can be carried to the bridge, and a marine engine of any power, and of this type, can be driven by the officer there, and this is an advantage of value, particularly for war ships or cruisers. The same construction renders these engines well adapted for use as winding-engines for collieries and mines. They also start themselves directly steam is turned on, and one special peculiarity is that they are found to run silently, and are eminently suited for places where this peculiarity will be thoroughly appreciated. As there are no unbalanced parts, the engine runs noiselessly, and without any vibration that can be communicated to the ship. It can also be arranged for twin screws, or to be run at a high speed, and under the latter condition is eminently suitable for driving the guide blade propeller, invented by the author now just twenty years ago.

Hydraulic engines are made on the same general principle, differing from steam engines in the valve setting,

which ensures a full supply of water up to the termination of every stroke, and in the mode of governing. This is done by changing the positions of the cylinder stud and that of the main shaft, and as this eccentricity determines the stroke just like the radius of a crank determines the stroke of a piston, there is a ready means provided by which this class of hydraulic engine can be governed. A supplementary hydraulic engine is employed to effect the necessary transfer, and the governor has no further duty to perform than to move the valves of this other engines, so that there is no difficulty in governing and maintaining a uniform speed with the advantage of using water pressure just equivalent to the work performed.

These hydraulic engines are eminently suitable for use as domestic motors, driven by the ordinary water main pressure, and performing such laborious work as driving knife-cutting machines, and they run with perfect uniformity.

They can also be employed for electric lighting purposes, and driven from the mains of the Hydraulic Power Supply Company, or any other source of power.

The largest yet made is used for driving a dynamo producing current for 100 incandescent lights.

A NEW SYSTEM OF ALTERNATE CURRENT MOTORS AND TRANSFORMERS.*

BY NIKOLA TESLA.

In the presence of the existing diversity of opinion regarding the relative merits of the alternate and continuous current systems, great importance is attached to the question whether alternate currents can be successfully utilised in the operation of motors. The transformers, with their numerous advantages, have afforded us a relatively perfect system of distribution, and although, as in all branches of the art, many improvements are desirable, comparatively little remains to be done in this direction. The transmission of power, on the contrary, has been almost entirely confined to the use of continuous currents, and notwithstanding that many efforts have been made to utilise alternate currents for this purpose, they have, up to the present, at least, as far as known, failed to give the result desired. Of the various motors adapted to be used on alternate current circuits the following have been mentioned:—1. A series motor with subdivided field. 2. An alternate current generator having its field excited by continuous currents. 3. Elhu Thomson's motor. 4. A combined alternate and continuous current motor. Two more motors of this kind have suggested themselves to me. 1. A motor with one of its circuits in series with a transformer and the other in the secondary of the transformer. 2. A motor having its armature circuit connected to the generator and the field coils closed upon themselves. These, however, I mention only incidentally.

The subject which I now have the pleasure of bringing to your notice is a novel system of electric distribution and transmission of power by means of alternate currents, affording peculiar advantages, particularly in the way of motors, which I am confident will at once establish the superior adaptability of these currents to the transmission of power, and will show that many results heretofore unattainable can be reached by their use; results which are very much desired in the practical operation of such systems, and which cannot be accomplished by means of continuous currents.

Before going into a detailed description of this system, I think it necessary to make a few remarks with reference to certain conditions existing in continuous current generators and motors, which, although generally known, are frequently disregarded.

In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator, a complicated device and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed cannot be utilised in the motor, but they must—again by means of a similar unreliable device—be reconverted into their original state of alternate currents. The function of

* Read before the American Institute of Electrical Engineers, May 16.

the commutator is entirely external, and in no way does it affect the external working of the machines. In reality, therefore, all machines are alternate current machines, the currents appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a more direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by such currents.

But the operation of the commutator on a motor is two-fold; firstly, it reverses the currents through the motor, and secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the system—that is to say, the directing of the alternate currents on the generator and reversing the direct currents on the motor—be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and the question presented itself, How to perform this operation by the direct action of alternate currents? I will now proceed to show how this result was accomplished.

In the first experiment a drum armature was provided with two coils at right angles to each other, and the ends of these coils were connected to two pairs of insulated contact rings as usual. A ring was then made of thin insulated plates of sheet iron, and wound with four coils, each two opposite coils being connected together so as to produce free poles on diametrically opposite sides of the ring. The remaining free ends of the coils were then connected to the contact rings of the generator armature so as to form two independent circuits, as indicated in Fig. 9. It may now be seen what results were secured in this combination, and with this view I would refer to the diagrams, Figs. 1 to 8a. The field of the generator being independently excited, the rotation of the armature sets up currents

in the coils c varying in strength and direction in the well-known manner. In the position shown in Fig. 1 the current in coil c is nil, while coil c_1 is traversed by its maximum current, and the connections may be such that the ring is magnetised by the coils c as indicated by the letters N S, in Fig. 1a, the magnetising effect of the coils c being nil, since these coils are included in the circuit of coil c .

In Fig. 2 the armature coils are shown in a more advanced position, one eighth of one revolution being completed. Fig. 2a illustrates the corresponding magnetic condition of the ring. At this moment the coil c generates a current of the same direction as previously, but weaker, producing the poles n_1, s_1 upon the ring; the coil c also generates a

current of the same direction, and the connections may be such that the coils c produce the poles n, s , as shown in Fig. 2a. The resulting polarity is indicated by the letters N S, and it will be observed that the poles of the ring have been shifted one-eighth of the periphery of the same.

In Fig. 3 the armature has completed one-quarter of one revolution. In this phase the current in coil c is a maximum, and of such direction as to produce the poles N S, in Fig. 3a, whereas the current in coil c_1 is nil, this coil being at its neutral position. The poles, N S, in Fig.

3a are thus shifted one quarter of the circumference of the ring.

Fig. 4 shows the coils c in a still more advanced position, the armature having completed three eighths of one revolution. At that moment the coil c still generates a current of the same direction as before, but of less strength, producing the comparatively weaker poles n, s , in Fig. 4a. The current in the coil c_1 is of the same strength, but of opposite direction. Its effect is, therefore, to produce upon the ring the poles n_1 and s_1 as indicated, and a polarity N S results, the poles now being shifted three eighths of the periphery of the ring.

In Fig. 5, one-half of one revolution of the armature is completed, and the resulting magnetic condition of the ring is indicated in Fig. 5a. Now, the current in coil c is nil, while the coil c_1 yields its maximum current, which is of the same direction as previously; the magnetising effect is therefore due to the coils c_1 alone, and, referring to Fig. 5a, it will be observed that the poles, N S, are shifted one-half of the circumference of the ring. During the next half revolution the operations are repeated, as represented in the Figs. 6 to 8a.

A reference to the diagrams will make it clear that during one revolution of the armature the poles of the ring are shifted once around its periphery, and each revolution producing like effects, a rapid whirling of the poles in

harmony with the rotation of the armature is the result. If the connections of either one of the circuits in the ring are reversed, the shifting of the poles is made to progress in the opposite direction, but the operation is identically the same. Instead of using four wires, with like result, three wires may be used, one forming a common return for both circuits.

This rotation or whirling of the poles manifests itself in a series of curious phenomena. If a delicately pivoted disc of steel or other magnetic metal, Fig. 9, is approached to the ring, it is set in rapid rotation, the direction of rotation varying with the position of the disc. For instance, noting the direction outside of the ring, it will be found that inside the ring it turns in an opposite direction, while it is unaffected if placed in a position symmetrical to the ring.

This is easily explained. Each time that a pole approaches it induces an opposite pole in the nearest point on the disc, and an attraction is produced upon that point. Owing to this, as the pole is shifted further away from the disc a tangential pull is exerted upon the same, and the action being constantly repeated a more or less rapid rotation of the disc is the result. As the pull is exerted mainly upon that part which is nearest to the ring, the rotation outside and inside, or right and left respectively, is in opposite directions. When placed symmetrically to the ring, the pull on opposite sides of the disc being equal, no rotation

Fig. 7.

Fig. 7a.

results. The action is based on the magnetic inertia of the iron; for this reason a disc of hard steel is much more affected than a disc of soft iron, the latter being capable of very rapid variations of magnetism. Such a disc has proved to be a very useful instrument in all these investigations, as it has enabled me to detect any irregularity in the action. A curious effect is also produced upon iron filings. By placing some upon a paper, and holding them externally quite close to the ring, they are set in a vibrating motion, remaining in the same place, although the paper may be moved back and forth; but in lifting the paper to a certain height which seems to be dependent on the intensity of the poles and the speed of rotation, they are thrown away in a direction always opposite to the supposed movement of the poles. If a paper with filings is put flat upon the ring

Fig. 8.

Fig. 8a.

and the current turned on suddenly, the existence of a magnetic whirl may be easily observed.

To demonstrate the complete analogy between the ring and a revolving magnet, a strongly energized electro-magnet was rotated by mechanical power, and phenomena identical in every particular to those mentioned above were observed.

Obviously, the rotation of the poles produces corresponding inductive effects, and may be utilised to generate currents in a closed conductor placed within the influence of the poles. For this purpose it is convenient to wind a ring

Fig. 9.

with two sets of superimposed coils, forming respectively the primary and secondary circuits. In order to secure the most economical results the magnetic circuit should be completely closed, as shown in Fig. 10, and with this object in view the construction may be modified at will.

The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator and determining the magnetising effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be

secured as though the shifting were effected by means of a commutator with an infinite number of bars. In such case the theoretical relation between the energising effect of each set of primary coils and their resultant magnetising effect may be expressed by the equation of a circle having its centre coinciding with that of an orthogonal system of axes, and in which the radius represents the resultant and the co-ordinates both of its components. These are then respectively the sine and cosine of the angle, α , between the radius and one of the axes (ox). Referring to Fig. 11* we have $r^2 = x^2 + y^2$; where $x = r \cos. \alpha$, and $y = r \sin. \alpha$.

Assuming the magnetising effect of each set of coils in the transformer to be proportional to the current—which may be admitted for weak degrees of magnetisation—then $x = Kc$ and $y = Kc'$, where K is a constant and c and c' the current in both sets of coils respectively. Supposing, further, the field of the generator to be uniform, we have for constant speed $c' = K^1 \sin. \alpha$, and $c = K^1 \sin. (90^\circ + \alpha) = K^1 \cos. \alpha$, where K^1 is a constant. See Fig. 12

Fig. 10.

Therefore, $x = Kc = KK^1 \cos. \alpha$
 $y = Kc' = KK^1 \sin. \alpha$, and
 $KK^1 = r$.

That is, for a uniform field the disposition of the two coils at right angles will secure the theoretical result, and the intensity of the shifting poles will be constant. But from $r^2 = x^2 + y^2$ it follows that for $y = 0$, $x = r$; it follows that the joint magnetising effect of both sets of coils should be equal to the effect of one set when at its maximum action. In transformers, and in a certain class of motors, the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

In applying this principle to the construction of motor, two typical forms of motor have been developed. First, a form having a comparatively small rotary effort at the

Fig. 14.

start, but maintaining a perfectly uniform speed at all loads, which motor has been termed synchronous. Second, a form possessing a great rotary effort at the start, the speed being dependent on the load.

These motors may be operated in three different ways: 1. By the alternate currents of the source only. 2. By a combined action of these and of induced currents. 3. By the joint action of alternate and continuous currents.

The simplest form of a synchronous motor is obtained by winding a laminated ring provided with pole projections with four coils, and connecting the same in the manner

* By an error of engraving, Figs. 11, 12, and 13 cannot be given. Fortunately Fig. 11 and 12 are simple trigonometrical diagrams which the reader can easily construct from the text—Ed. E.E.

before indicated. An iron disc, having a segment cut away on each side, may be used as an armature. Such a motor is shown in Fig. 9. The disc being arranged to rotate freely within the ring in close proximity to the projections, it is evident that as the poles are shifted it will, owing to its tendency to place itself in such a position as to embrace the greatest number of the lines of force, closely follow the movement of the poles, and its motion will be synchronous with that of the armature of the generator—that is, in the peculiar disposition shown in Fig. 9, in which the armature produces by one revolution two current impulses in each of the circuits. It is evident that if, by one revolution of the armature, a greater number of impulses is produced, the speed of the motor will be correspondingly increased. Considering that the attraction exerted upon the disc is greatest when the same is in close proximity to the poles, it follows that such a motor will maintain exactly the same speed at all loads within the limits of its capacity.

To facilitate the starting, the disc may be provided with a coil closed upon itself. The advantage secured by such a coil is evident. On the start, the currents set up in the coil strongly energise the disc and increase the attraction exerted upon the same by the ring, and currents are generated in the coil as long as the speed of the armature is inferior to that of the poles. Considerable work may be performed by such a motor even if the speed be below normal. The intensity of the poles being constant, no currents will be generated in the coil when the motor is turning at its normal speed.

Instead of closing the coil upon itself, its ends may be connected to two insulated sliding rings, and a continuous current supplied to these from a suitable generator. The proper way to start such a motor is to close the coil upon itself until the normal speed is reached, or nearly so, and then turn on the continuous current. If the disc be very strongly energised by a continuous current, the motor may not be able to start, but if it be weakly energised, or generally so that the magnetising effect of the ring is preponderating, it will start and reach the normal speed. Such a motor will maintain absolutely the same speed at all loads. It has also been found that if the motive power of the generator is not excessive, by checking the motor the speed of the generator is diminished in synchronism with that of the motor. It is characteristic of this form of motor that it cannot be reversed by reversing the continuous current through the coil.

The synchronism of these motors may be demonstrated experimentally in a variety of ways. For this purpose it is best to employ a motor consisting of a stationary field magnet and an armature arranged to rotate within the same, as indicated in Fig. 13. In this case the shifting of the poles of the armature produces a rotation of the latter in the opposite direction. It results therefrom that when the normal speed is reached, the poles of the armature assume fixed position relatively to the field magnet and the same is magnetised by induction, exhibiting a distinct pole on each of the pole pieces. If a piece of soft iron is approached to the field magnet, it will at the start be attracted with a rapid vibrating motion produced by the reversals of polarity of the magnet; but as the speed of the armature increases the vibrations become less and less frequent, and finally entirely cease. Then the iron is weakly but permanently attracted, showing that the synchronism is reached and the field magnet energised by induction.

The disc may also be used for the experiment. If held quite close to the armature, it will turn as long as the speed of rotation of the poles exceeds that of the armature; but when the normal speed is reached, or very nearly so, it ceases to rotate and is permanently attracted.

A crude but illustrative experiment is made with an incandescent lamp. Placing the lamp in circuit with the continuous current generator, and in series with the magnet-coil, rapid fluctuations are observed in the light in consequence of the induced currents set up in the coil at the start; the speed increasing, the fluctuations occur at longer intervals, until they entirely disappear, showing that the motor has attained its normal speed.

A telephone receiver affords a most sensitive instrument; when connected to any circuit in the motor the synchronism

may be easily detected on the disappearance of the induced currents.

In motors of the synchronous type it is desirable to maintain the quantity of the shifting magnetism constant, especially if the magnets are not properly subdivided.

To obtain a rotary effort in these motors was the subject of long thought. In order to secure this result, it was necessary to make such a disposition that while the poles of one element of the motor are shifted by the alternate currents of the source, the poles produced upon the other elements should always be maintained in the proper relation to the former, irrespective of the speed of the motor. Such a condition exists in a continuous current motor; but in a synchronous motor, such as described, this condition is fulfilled only when the speed is normal.

The object has been attained by placing within the ring a properly subdivided cylindrical iron core wound with several independent coils closed upon themselves. Two coils at right angles are sufficient, as in Fig. 14, but a greater number may be advantageously employed. It results from this disposition that when the poles of the ring are shifted, currents are generated in the closed armature coils. These currents are the most intense at or near the points of the greatest density of the lines of force, and their effect is to produce poles upon the armature at right angles to those of the ring, at least theoretically so; and since this action is entirely independent of the speed—that is, as far as the location of the poles is concerned—a continuous pull is exerted upon the periphery of the armature. In many respects these motors are similar to the continuous current motors. If load is put on, the speed, and also the resistance of the motor, is diminished and more current is made to pass through the energising coils, thus increasing the effect. Upon the load being taken off, the counter electromotive force increases and less current passes through the primary or energising coils. Without any load the speed is very nearly equal to that of the shifting poles of the field magnet.

It will be found that the rotary effort in these motors fully equals that of the continuous current motors. The effort seems to be greatest when both armature and field magnet are without any projections; but as in such dispositions the field cannot be very concentrated, probably the best results will be obtained by leaving pole projections on one of the elements only. Generally, it may be stated that the projections diminish the torque and produce a tendency to synchronism.

A characteristic feature of motors of this kind is their capacity of being very rapidly reversed. This follows from the peculiar action of the motor. Suppose the armature to be rotating and the direction of rotation of the poles to be reversed, the apparatus then represents a dynamo machine, the power to drive this machine being the momentum stored up in the armature, and its speed being the sum of the speeds of the armature and the poles. If we now consider that the power to drive such a dynamo would be very nearly proportional to the third power of the speed, for this reason alone the armature should be quickly reversed. But simultaneously with the reversal another element is brought into action; namely, as the movement of the poles with respect to the armature is reversed, the motor acts like a transformer in which the resistance of the secondary circuit would be abnormally diminished by producing in this circuit an additional E.M.F. Owing to these causes the reversal is instantaneous.

If it is desirable to secure a constant speed, and at the same time a certain effort at the start, this result may be easily attained in a variety of ways. For instance, two armatures, one for torque, and the other for synchronism, may be fastened on the same shaft, and any desired preponderance may be given to either one; or an armature may be wound for rotary effort, but a more or less pronounced tendency to synchronism may be given to it by properly constructing the iron core; and in many other ways.

As a means of obtaining the required phase of the currents in both the circuits, the disposition of the two coils at right angles is the simplest, securing the most uniform action; but the phase may be obtained in many other ways, varying with the machine employed. Any of the dynamos

at present in use may be easily adapted for this purpose by making connections to proper points of the generating coils. In closed circuit armatures, such as used in the continuous current systems, it is best to make four derivations from equidistant points or bars of the commutator, and to connect the same to four insulated sliding rings on the shaft. In this case each of the motor circuits is connected to two diametrically opposite bars of the commutator. In such a disposition the motor may also be operated at half the potential, and on the three-wire plan, by connecting the motor circuits in the proper order to three of the contact rings.

In multipolar dynamo machines, such as use the converter systems, the phase is conveniently obtained by winding upon the armature two series of coils in such a manner that while the coils of one set or series are at their maximum production of current, the coils of the other will be at their neutral position, or nearly so, whereby both sets of coils may be subjected simultaneously or successively to the inducing action of the field-magnets.

Generally, the circuits in the motor will be similarly disposed, and various arrangements may be made to fulfil the requirements; but the simplest and most practicable is to arrange primary circuits on stationary parts of the motor, thereby obviating, at least, in certain forms, the employment of sliding contacts. In such a case the magnet coils are connected alternately in both the circuits; that is, 1, 3, 5 in one, and 2, 4, 6 in the other Fig. 15, and the coils of each set of series may be connected all in the same manner, or alternately in opposition, Fig. 16. In the latter case a motor, with half the number of poles, will result, and its action will be correspondingly modified, Fig. 17.

The employment of multipolar motors secures in this system an advantage much desired and unattainable in the continuous current system, and that is, that a motor may be made to run exactly at a predetermined speed irrespective of imperfections in construction of the load, and, within certain limits, of electromotive force and current strength.

In a general distribution system of this kind the following plan should be adopted. At the central station of supply, a generator should be provided having a considerable number of poles. The motors operated from this generator should be of the synchronous type, but possessing sufficient rotary effort to insure their starting. With the observance of proper rules of construction it may be admitted that the speed of each motor will be in some inverse proportion to its size, and the number of poles should be chosen accordingly. Still, exceptional demands may modify this rule. In view of this, it will be advantageous to provide each motor with a greater number of pole projections or coils, the number being preferably a multiple of two and three. By this means, by simply changing the connections of the coils, the motor may be adapted to any probable demands.

If the number of the poles in the motor is even, the action will be harmonious and the proper result will be obtained; if this is not the case the best plan to be followed is to make a motor with a double number of poles, and connect the same in the manner before indicated, so that half the number of poles result. Suppose, for instance, that the generator has twelve poles and it would be desired to obtain a speed equal to $\frac{1}{2}$ of the speed of the generator. This would require a motor with seven pole projections or magnets, and such a motor could not be properly connected in the circuits unless fourteen armature coils would be provided, which would necessitate the employment of sliding contacts. To avoid this, the motor should be pro-

vided with fourteen magnets and seven connected in each circuit, the magnets in each circuit alternating among themselves. The armature should have fourteen closed coils. The action of the motor will not be quite as perfect as in the case of an even number of poles, but the drawback will not be of a serious nature.

However, the disadvantages resulting from this unsymmetrical form will be reduced in the same proportion as the number of the poles is augmented.

If the generator has, say, n , and the motor n_1 poles, the speed of the motor will be equal to that of the generator multiplied by $\frac{n}{n_1}$.

The speed of the motor will generally be dependent on the number of the poles, but there may be exceptions to this rule. The speed may be modified by the phase of the currents in the circuits, or by the character of the current impulses or by intervals between each or between groups of impulses. Some of the possible cases are indicated in the diagrams, Figs. 18, 19, 20 and 21, which are self-explanatory. Fig. 18 represents the condition generally existing, and which secures the best result. In such a case, if the typical form of motor illustrated in Fig. 14 is employed, one complete wave in each circuit will produce one revolution of the motor. In Fig. 19 the same result will be effected by one wave in each circuit; in Fig. 20 by two, and in Fig. 21 by four waves.

By such means any desired speed may be attained; that is, at least within the limits of practical demands. This system possesses this advantage besides others, resulting from simplicity. At full loads, the motors show an efficiency fully equal to that of the continuous current motors. The transformers present an additional advantage in their capability of operating motors. They are capable of similar modifications in construction, and will facilitate the introduction of motors and their adaptation to practical demands. Their efficiency should be higher than that of the present transformers, and I base my assertion on the following:

In a transformer as constructed at present we produce the currents in the secondary circuit by varying the strength of the primary or exciting currents. If we admit proportionality with respect to the iron core, the inductive effect exerted upon the secondary coil will be proportional to the numerical sum of the variations in the strength of the exciting current per unit of time: whence it follows that for a given variation, any prolongation of the primary current will result in a proportional loss. In order to obtain rapid variations in the strength of the current, essential to efficient induction, a great number of undulations are required and employed. From this, various disadvantages result. These are increased cost and diminished efficiency of the generator, more waste of energy in heating the cores, and also diminished output of the transformer, since the core is not properly utilised, the reversals being too rapid. The inductive effect is also very small in certain phases, as will be apparent from a graphic representation, and there may be periods of inaction, if there are intervals between the succeeding current impulses or waves. In producing a shifting of the poles in the transformer, and thereby inducing currents, the induction is of the ideal character, being always maintained at its maximum action. It is also reasonable to assume that by a shifting of the poles less energy will be wasted than by reversals.

FACETIÆ.

SHE SAW THE GOLD.—"Mamma, I know it's true about the golden streets in heaven." "Why, how do you know that, darling?" "Because, when I was out with nurse last night, something made a great noise, and the sky split clear across: and then I saw the gold shining through."

A SNAKE STORY. Swan's stand at the Inventions' Exhibition was one mass of incandescent lamps, and caused a great deal of curiosity to arise in the minds of country visitors. "Why, Maria," said one of two old dames after prying about inquisitively, "there's little snakes in them glass bottles." Fact!

PROTECTION OF THE HUMAN BODY FROM DANGEROUS CURRENTS.*

BY PATRICK H. DELANY.

Since the object of reading a paper before this Society should be the enlightenment of members on the subject under consideration by the presentation of facts developed by experimentation, or of theories supported by a reasonable amount of investigation, I must apologise for my delinquency in both respects, and trust to the kind indulgence of the Society in making a few suggestions, with a view of eliciting information and opinions from those whose experience and familiarity with the subject enables them to speak with authority.

I allude to what are considered dangerous currents and their effect on the human body. That there is danger in handling conductors conveying high tension currents must be generally admitted. The question, therefore, is, Can fatal results from such currents be wholly or partially averted? All will agree that, with proper care on the part of the companies, and intelligent co-operation on the part of employees, but little would be heard of the danger of electric currents. But companies are economical, and employees are careless. Familiarity with danger breeds contempt for it. This is exemplified almost daily in every department of industry. A new man in a powder mill will exercise the greatest care and observe all the rules of the establishment faithfully. In a few months the same man will smoke a pipe over an open powder keg.

Protection is necessary principally for those who through carelessness or ignorance fail to protect themselves. It has been claimed that there can be no such thing as an accident—that Nature has none, and that all so-called accidents are simply the results of miscalculation, bad judgment or carelessness. But it must be remembered that the vigilance of the most alert will sometimes relax, and this to them is the moment of danger.

Realising that something should be done to protect dynamo men and wire handlers from injury from powerful currents, I a few years since invented a device for shunting the vital parts of the body. Partly on account of a pressure of business in other branches of electricity, but principally owing to a hesitancy in bringing out a device about the efficacy of which there seemed to be some doubt, its introduction to scientific criticism was delayed until a few weeks ago. As the references made to the question in the electrical papers have failed to elicit an expression of opinion satisfactory to any degree, it has been deemed advisable to bring the subject before this meeting.

The question to be determined is, to what extent a wire of practically no resistance, extending from one wrist to the other, and bound around the wrists in numerous convolutions so as to make good, but not uncomfortable, contact, will protect the vital parts of the body from fatal injury when it is placed in the path of a dangerous current through contact at the hands. It is claimed by some that the current having once entered the muscles, veins and tissue at the hands, will not leave the arms at the wrists and follow the shorter path of the wire, but will continue its course to the arms and body alone. The other opinion is that the greater portion of the current received at the hands will leave the arms at the wrists and follow the wire. The problem seems a difficult one to solve. So much depends on the condition of the person at the time of receiving a shock, a large number of tests would be necessary to arrive at results which would afford a safe basis for calculation. A few years ago Dr. Stone, connected with one of the London hospitals, made a series of interesting experiments upon patients afflicted with various ailments, with a view of determining whether or not fluctuation in their physical condition affected the electrical conductivity or resistance of their bodies. The results proved, according to my recollection, that great changes took place in the electrical resistance of the patients experimented upon from day to day, and that there was a direct influence manifested by the rise and fall of different diseases upon the electrical conductivity of the body as a whole or in part. An account of

Dr. Stone's experiments was published in *Nature* at the time. But while the experiments are most valuable for the purpose for which they were intended, they throw but little light on the subject of dangerous currents and protection from fatal injury.

Last September there was published in the *Electrical Review* of London a paper on "Shocks from Alternating Currents," by Mr. G. L. Addenbrooke, who for some time previous had charge of the Grosvenor Gallery installation, where a primary current of 2,500 volts was constantly employed. While no one had ever come in contact with both mains at once, the writer stated that even if such an accident had happened he was "by no means prepared to assert that the result would undoubtedly be fatal." "Indeed," says he, "I rather incline to the opinion that if the subject of the shock were healthy, and the circumstances under which he received it were favourable, the chances are he would survive."

I cannot make out what Mr. Addenbrooke means by receiving 2,500 volts under favourable circumstances. It seems to me, if they are received at all, the circumstance could not be other than unfavourable. Mr. Addenbrooke himself received a severe shock, and as he speaks from experience I quote his account of how it affected him: "The primary effect of the passage of the current through the body, is of course, to contract the muscles. The amount and persistence of this contraction depend on the quantity of the current flowing, or, as it is usually designated, the intensity of the shock, and varies from a simple twitching of the limbs to complete and intense contraction or rigour of apparently every muscle in the body. In this latter case the current completely supersedes the action of the mind over everything capable of contraction or movement. Consciousness, however, is apparently rarely, if ever, lost, though the subject may be entirely unable to make any motion, cry out, or do anything to help himself. If aid is not near, such a state may be maintained for some time. On release from such a position by extraneous or natural causes, the subject is usually dazed, but if at all unconscious, soon recovers completely and experiences no further functional disturbance than the debility and nervousness naturally following such a severe strain on the system." While admitting that fatal shocks are possible, this gentleman gives it as his opinion that "if the shock is not sufficient to cause instantaneous collapse, apparently the body can bear the strain of the continued passage of the current for some time," and that death is caused by paralysis of the involuntary muscles controlling the heart and lungs, and that the preliminary stages of total collapse are analogous to what occurs when drowning. Referring to the local action of the current on the body where it enters and leaves, this writer also says: "If the contact is good, that is, if it consists of a good area, say of over a couple of square inches of a fairly moist skin pressed with moderate firmness against a metallic body or other good conductor, no visible injury may result. For instance, a man will often get burnt about the hands, but his feet, by which the current leaves, will be unaffected, or only slightly reddened or inflamed. Burning of the hands or other parts of the body will occur when there is imperfect contact of the body with the conductor, coming in contact with a bad or semi-conductor such as a dirty or carbonised surface. The burning is caused by the absolute setting up of an arc."

It seems to me this gentleman's views, based, as we are led to believe, on actual experience, are somewhat paradoxical. And surely numerous cases of deaths from currents recently disprove many of Mr. Addenbrooke's deductions. True, nothing short of death is made public, so that there is but little information to go upon relating to the instances which must be of frequent occurrence where men are almost killed by electric shocks. In all cases that have come to light, whether simply injurious or cases of death, the parts of the body coming in contact with the current have been badly burned. The unfortunate "Trouble Hunter," who lost his life a few days since, was not only burned at the hands but at the knees. In cases where the shock is not instantly fatal, may it not be that the burning of the flesh at the points of contact is so great as to destroy to a considerable extent the conduct-

* Read before the American Institute of Electrical Engineers, May 16, 1888.

ing substance in contact with the wire, and thereby cause a fall in the current passing through the body? It is certainly owing to the fact of the body being a very poor conductor that harm is done. If it offered no resistance, there would be no realisation that a current was passing through it. An arc would be created at the point of contact, provided the contact was *imperfect*, but the body itself would be uninjured. It seems to me that the human body must be viewed as any other semiconductor, with the exception, perhaps, of susceptibility to greater change under the continued action of a current, owing to the fluids which it contains. It is owing to its resistance that a carbon filament becomes incandescent. The carbon rod of an electric lamp is not consumed except at the point where the arc is formed by the resistance of attenuated particles under combustion. Any conducting substance placed in the path of more current than it is capable of conveying must be heated, consumed, or decomposed, according to its nature and in proportion to the discrepancy between the conducting capacity of the conductor and the sum of the current.

Now, if we liken the human body from hand to hand to a canvas hose or tube filled with water, and which allows a certain quantity of moisture to ooze through the surface, corresponding to the moisture of the skin, and if this be inserted in a circuit, connection being made at the extreme ends, corresponding to the hands, and a shunt wire of minimum resistance be wound around the tube two or three inches from the ends, corresponding, say, to the wrists, we can, perhaps, more understandingly speculate on the action of a dangerous current on the human body, contact being made at the hands and the shunt wire encircling the wrists. It should be borne in mind that the contact between the shunt wire and wrists is much better than the contact at the hands, since the wrists are more tender than the hands. Now, referring to the tube and assuming that the contacts at the ends have improved by reason of the currents eating its way into the water, does it not follow that the current, instead of following the entire length of the tube of water, offering, say, thirty times the resistance of the two or three inches of water from the end of the tube to the shunt wire, and several thousand times the resistance of the shunt wire itself, will, to a great extent, pass from the tube to the shunt wire, and in its passage *improve* the contact at that point as it did at the ends in entering the tube? I have often noticed that upon receiving a shock of 150 to 250 volts profuse perspiration instantly followed. This would greatly improve the contact at the wrists above the normal, so that it would seem impossible that the current should confine itself to the fluids and muscles of the body in preference to the wire when separated from the wire only by a thin tender skin filled with moisture.

In considering the danger point of currents it seems reasonable to recognise the same law, or rather recognise the absence of any law, governing other destructive agencies. Let it be concussion, strain, asphyxia, poison, or other enemy of endurance, there are hardly two cases alike. One man may emerge with but slight injury from a cause which to another man would be death. Why should it not be so in the matter of electric shock? Death, of course, must be the consequence of a certain degree of cause. If 2,000 volts are necessary to kill in any instance, one volt less would avert death, while shunting 100 or 500 volts would leave a proportionate margin of safety. Fatal results through the medium of electricity do not come by jumps any more than by any other force or element of destruction. There is in this subtle agency, as in all others, a last straw which breaks the camel's back—a last volt which does the final harm. Hence the importance of protecting, as far as possible, those exposed to this danger.

Regarding the immediate cause of death or the effect of currents on the substances of the body, we must look to the medical men for light. Probably all subjected to shock might not be similarly affected. In one case it might be the heart, in another the brain, and in others the lungs that might be injured. Why not have a thorough investigation of this subject, and then, perhaps, wire handlers may be subjected to an examination before they are allowed to engage in such work, just as men are examined for various other duties.

There seems to be so little known about these matters, I shall feel gratified if this paper serves as even a feeble incitement to discussion and investigation, as I can conceive of no subject offering a more humane incentive.

THE S.S. "INANDA."

The steamship "Inanda," by Messrs Hall, Russell and Co., Aberdeen, belonging to Messrs. John T. Rennie and Sons, 6, East India-avenue, just built for trading to Natal, South Africa, has been fitted with electric light by Messrs. J. H. Holmes and Co., Newcastle on Tyne. The installation is a small one, but is very neatly and carefully fitted throughout. The engine, 6 h.p. nominal, is one of the "Archer" type, by Tangye Bros., Birmingham, direct driving at 280 revolutions with 80 lb. pressure. The dynamo is Messrs. Holmes' "Castle" type; a larger size is used with this slow speed, and gives 65 amperes at 55 volts. Edison-Swan 50 volt incandescent lamps are used, and the wiring throughout is on the single wire or earth return system. One of the main cables is cut off, and a bare loop is made, which is bolted securely to the framework of the ship. Only one wire is therefore used for wiring throughout, the return being to the framework of the metal fittings of the lamp. Drake and Gorham holders, with porcelain bases, are used, and short brackets for the cabins, with obscured globes, are fitted with push switches in the bases of each bracket, designed by the same firm. The switchboard is arranged with Holmes' instantaneous break main switches near the dynamo and engine, which are installed in a small compartment the height of a man, up a few stairs in the main engine-room, and the running is extremely smooth and silent. There are sixty-four 16 c.p. lamps in all, and the hatches are fitted with three large "Sunbeam" lamps of 200 c.p., with reflectors, hung with running gear to a spar above. The engine room is fitted with portable hand lamps, with 30 ft. of flexible, and the side lights, red and green, have each a sliding fitting with two incandescent lamps each, which can be replaced with the usual oil lamps if necessary.

PHYSICAL SOCIETY—June 9.

Prof. BLINDE, President, in the chair.

Mr. J. L. Howard, D.Sc., was elected a member of the Society. The following papers were read:—

"On the Analogy between Dilute Solutions and Gases as regards Gay-Lussac's and Boyle's and Avogadro's Law," by Prof. Van't Hoff, presented by Prof. Ramsay, F.R.S.

"On a Method of Comparing very Unequal Capacities," by Mr. A. B. Pison, D.Sc. One coating of each condenser is joined to earth and to one end, A, of a high resistance 20,000 or 30,000 ohms, through which a current is flowing. The small condenser is charged to the P.D. existing between the ends, A B, of the resistance, and discharged into the large one. This is repeated a great number of times. If C be a point between A and B, the resistance between A and C may be varied until the P.D. between them is equal to that between the coatings of the condensers after a operation. If the insulated coatings be now joined to C through a galvanometer, no deflection will result. The relation between the capacities C_1 and C_2 of the large and small condensers is given by $\left(1 + \frac{C_2}{C_1}\right) = \frac{R_{AB}}{R_{AC}}$, where R_{AB} , R_{AC} are the resistances between A B and B C respectively.

Since time is required to perform the operations, the instantaneous capacities cannot be compared, and accordingly the measurements are taken after a definite time of electrification. A special rotating key was shown for performing ten operations per revolution, in which a trigger arrangement was provided for stopping the rotation after a predetermined integral number of revolutions. The method has been used for comparing a small air condenser with a microfarad. The capacity of the former was also calculated electrostatically (correction being made for the edges) and that of the latter measured electromagnetically by a ballistic galvanometer. The results give a value for ϵ equal to 2.965×10^7 . In these experiments the capacity of the rotating key was allowed for. Under favourable conditions capacities in the ratio of 1 to 1,000 or 1 to 10,000 can be compared with an accuracy of 1 per cent.

Prof. Ayrton thought the novelty of the arrangement was in the rotating key, as the method of comparing unequal capacities by charging the smaller and discharging it into the larger a considerable number of times had been described and used by himself and Prof. Perry in their experiments on the specific inductive capacity of gases.

Mr. W. Lant-Carpenter exhibited a new form of lantern, recently constructed by Mr. Hughes, of Dalston. The mahogany body is

hexagonal, and each of the three front sides is provided with condensers and projecting arrangements. The back part opens to give access to the radiant which in this case is a Brookie-Pell lamp, but, if necessary, a lime light can be readily substituted. The lamp is fixed to the base-board, and the body can be rotated through 60 deg on either side of the central position thus allowing any of the three nozzles to be directed towards the screen. The three sets of condensers are placed so that their axes intersect at a point about which the radiant is placed. The centre nozzle is fitted as a lantern microscope, with alum cell, and various sets of condensing lens and objectives, and a space in front of the main condenser is provided for polarising apparatus. The focussing arrangement consists of a skew rack and pinion and a fine screw adjustment, and the whole microscope can be easily removed and a table polariscope substituted. The right hand nozzle is arranged for the projection of ordinary lantern slides, and the left hand one is provided with an adjustable slit for spectrum work. A small table, sliding on rails, serves to carry the prisms, and the same rails support projecting lenses.

Prof. S. P. Thompson congratulated Mr. Lant-Carpenter on his selection of the Brookie-Pell lamp as the radiant, for in addition to its being a focussing lamp, it was unique, in the fact that it worked satisfactorily on either constant current or constant potential circuit.

"Notes on Some Additions to the Kew Magnetometer," by Prof. H. Thorpe, F.R.S., and Prof. Rucker, F.R.S. In their magnet survey of Great Britain and Ireland the authors have experienced considerable difficulty in making the necessary adjustments of the small transit mirror used for determining the geographical N point from observations on the sun. To make the required adjustments, it is necessary to obtain an image of the cross wires reflected from the mirror, and, owing to the large amount of extraneous light and the insufficient illumination of the cross wires, the image is difficult to see. To exclude extraneous light, a tube is placed between the transit mirror and the telescope, and a small screen placed behind the mirror. The cross wires are illuminated by light reflected from a small platinum mirror introduced between the eye piece and the cross wires, which are viewed through a hole in its centre. The mirror is placed at 45 degs. to the axis, and reflects a considerable quantity of light on the cross wires when directed towards a bright part of the sky. In some cases it is advisable to take observations of the sun without first adjusting the transit mirror, and afterwards correct the error introduced thereby. To do this, a finely divided scale is placed in the plane of the cross wires, and from the position of the image, as indicated on the scale, the correction can be made. Observations taken with the mirror in adjustment, and others taken when out of adjustment and subsequently corrected, gave very concordant results.

The Rev. Father Perry said the improvements described were of great importance, for difficulties similar to those experienced by the authors had caused him to abandon the Kew magnetometer for field work, and to use a theodolite instead.

COMPANIES' MEETINGS.

THE INSTITUTE OF MEDICAL ELECTRICITY, LIMITED.

The first ordinary general meeting was held at Essex Hall, Essex street, W.C., on the 7th inst. Mr W. Lant Carpenter was voted to the chair. He explained that though the meeting was called in accordance with the requirements of the statute, the Directors had but little to report, since they had been unexpectedly obliged to delay the opening of an establishment in London. This was mainly owing to certain negotiations with the Royal College of Physicians, which, he hoped, however, would soon be satisfactorily completed, and they had reference to the appointment of medical officers to the institute. The Directors had given considerable attention to the welfare of the institute, having held sixteen Board meetings since the Company was registered. Mr F. L. Rawson, M.S.T.E. and E., had joined the Board, and it had been unanimously decided that no Directors' fees would be accepted till a dividend of 6 per cent. per annum should have been declared.

The meeting cordially approved the action of the Directors with reference to the Royal College of Physicians, and a resolution was passed confirming an agreement provisionally entered into by the board, by which the institute acquires the business of the Electrified Rooms Company, Limited, of London. This has been carried on for over twelve months with the warm approval and support of over forty local medical men, upon a similar principle to that adopted by this institute, viz., that no electrical treatment is administered to any patient without the concurrence and upon the prescription either of his own medical man or of the medical officer of the institute.

PROVISIONAL PATENTS, 1888.

JUNE 1.

8039. Improvements in or relating to the transformation or conversion of electric currents. Alfred Le Clercq and Achille Vansteenkiste, 6, Lord street, Liverpool.

8062. A combined electrical time switch and electrometer. Ferdinand Kleiner, 18, Buckingham-street, Strand, London.

JUNE 4.

8161. Bleaching paper pulp by electricity. Charles Cecil Nichols, of the firm of C. A. and H. Nichols, 21, Mincing lane, London, E.C., on behalf of the London Electric Bleaching Company. (Complete specification).

8081. Improvements in and relating to electrical bells, indicators, and such like. Walter Rowbotham and William Fox, 39, Lever street, Manchester, Lancashire.

8099. Improvements connected with electrical hoists or cranes. Rakes Evelyn Bell (inventor), John Francis Albright, and Jorgen H. Ferdinand Soli, Arc Works, Chalmersford.

8160. Production by electricity of chlorine and its oxygenated compounds, and their utilisation thereof. Emily Marie Hippolyte Andreoli, 62, Loughborough park, Brixton, S.W.

JUNE 5.

8170. Improvements in governing devices for electric motors and circuits. Herbert John Allwood, 52, Chancery lane, London. The Baxter Electric Manufacturing and Motor Company Incorporated, United States. (Complete specification.)

8171. Improvements in magneto-electric liquid level indicators. John Joseph Ghegan, 52, Chancery-lane, London. (Complete specification.)

8200. Improvements in electrical transformers. Walter Thomas Gooden and Henry Willock Ravenshaw, 23, Audlin's-road, Clapham, S.W.

JUNE 7.

8354. Improvements in the manufacture of depolarisers for primary or secondary electric batteries. Maurice Lec-lanche, 169, Fleet-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

JUNE 8, 1887.

8240. Improvements in galvanic batteries. John Randolph Hard and Thomas Wilson, 191, Fleet street, London, E.C.

JUNE 13, 1887.

8500. Improvements in conduits for electric wires or cables. Richard Solomon Waring, 24, Southampton-buildings, London.

JUNE 16, 1887.

8701. Improvements in and relating to the production and application of electric energy for lighting or other purposes. John Ross, 96, Buchanan street, Glasgow.

JUNE 19, 1887.

10,071. Improved fittings for electric incandescence lamps. Wm. Brooks Sayers, 231, Monument road, and Wilson Henry Sturge, 17, Frederick-road, both in Birmingham.

ATTEST 4, 1887.

10,740. Improvements in regulators for electric lamps. Sylvain Mathis, 45, Southampton-buildings, London.

OCTOBER 7, 1887.

13,601. Improvements in "automatic" coin-fired electrical machines, and in the method of displaying advertisements therein. John Hubert Davies and Alfred Thompson, 45, Southampton-buildings, London W.C.

OCTOBER 21, 1887.

14,346. An improved bell-pull electric-light switch. Andreas Peter Lundberg, 18, Regent road, Tollyington Park, London, N.

NOVEMBER 16, 1887.

15,703. A galvanic battery for medical purposes. John Court, 136, Brompton-road, London, S.W.

FEBRUARY 23, 1888.

2703. Improved means or apparatus for sounding at sea and elsewhere by electricity. Frederick Hargrave, 38, Chancery-lane, W.C.

MARCH 10, 1888.

3752. Manufacture of composition for the construction of roadways, pavements, building blocks, telegraph poles, railway sleepers, and similar articles, and for the manufacture of fire-proof and preservative paint. Oliver Inray, 28, Southampton buildings, London, W.C. (George Seth Lee, United States.)

APRIL 24, 1888.

6076. Electrical appliances for a mariner's compass to give alarm upon deviation from the ship's course. Augustus Gross, 45, Southampton-buildings, London, W.C.

SPECIFICATIONS PUBLISHED.

1887.

7189. Secondary batteries. W. H. Akester. 8d.

8206. Producing electric light by insertion of coin. D. H. Davies and J. M. Toantel. 8d.

8495. Electric lamps. A. M. Clark Berton. 1s. 1d.

9598. Electrical apparatus for working railway signals. I. A. Timmus. 8d.

1888.

3246. Electrical lamp and projector, &c. F. Walker. 8d.

3303. Registering the consumption of electric energy. H. H. Leigh. (Clere.) 8d.

5203. Transmitting sounds. L. J. LePontois. 8d.

1882.

4362. Distributing electricity. L. Gaulard and J. D. Gibbs. 8d.

Registered without articles of association, and therefore the clauses of the first schedule of the Companies Act, 1862, will apply.

NOTES.

House of Commons. The Electric Lighting Amendment Act was read a third time on Friday evening, June 15.

Telephoning to Lighthouses.—It is proposed shortly to connect the Faldystone Lighthouse with Plymouth by telephone.

Vienna.—The Austrian Government has granted the Anglo-American Brush Corporation a concession for public lighting in Vienna.

India.—Owing to the fall in exchange, the rates for foreign telegrams to Europe will be increased by 3 annas a word on the 1st of July.

Conversazione.—Invitations have been issued by the President of the Society of Telegraph-Engineers for a conversazione on the 10th July.

Crossley Bros.—Messrs. Crossley Bros., Limited, will open a warehouse and show-room for Otto gas engines in St. Bride-street, Ludgate-hill, next week.

Galvani Centenary. An interesting ceremony, the celebration of the centenary of Galvani's discoveries in electricity, was celebrated at Bologna on the 11th inst.

Book Received. "Short Lectures to Electrical Artisans," by Dr. J. A. Fleming (Spon, 1888). A second edition of this clear and interesting set of lectures has just been published.

Telephone Union. The United Telephone Company have tried to rush a Bill through the House of Commons, but the Metropolitan members have unanimously agreed not to support the Bill.

Disabled by Lightning. At Elizabeth, New Jersey, the arc lighting system was temporarily disabled by a lightning stroke during the storm of May 28, and every lamp was extinguished.

Perpignan.—The town of Perpignan is to be lighted by electricity from a central station, to be installed by M. Lamy, who has already established several other central stations in French country towns.

Ignifuge. A new paint called "Ignifuge Martin" is being introduced for prevention of fire risks. It may be used for painting wood casing for the electric light wires. The London agent is Mr. Walter Gilbert, 6, Dowgate hill, E.C.

Accumulators in America. The use of accumulators for public lighting is greatly extending in America. Kansas City is to have a plant of 10,000 lights, at which the accumulator system is to be used. Several other towns in Kansas are following suit.

Value of the Ohm. M. Wuitteumier has arrived at a fresh determination of the value of the ohm, by the method proposed by Lippmann. He gives it as the resistance of a column of mercury having a section of 1 millimetre square and a length of 106.27 centimetres.

Morley's Alternator. In our notice of this machine it should have been stated that the alternators to be erected in Oxford-street are at Mr. Pitchett's lighting station. For the illustrations used in our article, so far as regards Figs. 1, 2, and 3, we are indebted to the courtesy of our contemporary *Industries*.

Short System in Ohio. The Short series system of electric trams is being introduced at Columbus, Ohio, where

a plant of 250 h.p. is being erected, to operate 50 street cars on 10 miles of double track. Mr. Charles F. Brush, of Cleveland, is said to be interested in the enterprise, and Brush motors are to be used.

Cheap Aluminium. The Hon. F. J. Kingsbury and the son of Mr. Waterbury, Conn., are associated with some New York capitalists in a company for the manufacture of the alloys of aluminium and silicon produced by the furnaces of the Cowles Electric Smelting and Aluminium Company at Lockport, N.Y., on a large scale for the market.

Hot-Air Engine. M. Benier has invented an improved hot air engine, with which some important results have been achieved, according to *Dingler's Polytechnische Zeitung*. The working temperature is 200deg. to 240deg. centigrade, and the consumption of coke in a 6-h.p. engine was 3.3lb. per h.p. on light loads, and 2.1lb. on heavy loads.

Richmond Union Tramway.—This electric tramway, which we described last week, is one of the most extensive at present in use. Forty cars are now running from one station, and the cost, including depreciation and everything except executive expenses, proves to be only 4.32 cents (2.16d.) per car mile. The cars are crowded, and success seems guaranteed.

"Waring" Cables.—In response to enquiries respecting the hightension underground cables in Philadelphia, mentioned in our issue of 8th inst., the cables there referred to as working satisfactorily with a high tension current, are the "Waring" cables, eulogised by Mr. Preece in his paper on fire risks. We believe these cables will shortly be introduced to the English market.

New Filament. We hear that Messrs. Woodhouse and Rawson are introducing a new method of producing filaments for electric lamps of carbons of such hardness, fineness, and elasticity, that considerable power may be exerted in bending the filaments without breaking. Buttons made of the new carbon shine like jet, and will bend perceptibly under pressure with the fingers.

Women Glass-Blowers. The new Sawyer-Man factory in New York is an immense and well-furnished establishment. The mercury pump-room will have 240 pumps when complete. Where men glass-blowers were formerly employed, the superintendent has introduced women, who are, he says, more expert than the men, and are able to turn out several times more lamps at less expense.

Electric Damper. The Curtis damper regulator is finding much favour in the States. In this device, regulation by electricity has been applied to the movement of a damper in the flue of a steam boiler, so as to obtain a marvellous uniformity of boiler pressure, many of the regulators closing and opening the damper with a variation of boiler pressure inside of one pound, and maintaining the pressure with very slight variations.

The Earth's Magnetism in "Tempering."—A Philadelphia tool manufacturer instructs his workmen to hold large steel tools in a north and south line while they are being tempered. He says that many years ago he noticed that such tools would often fly apart when being tempered if held "east and west," and that the liability to such accidents was greatly lessened, if not entirely obviated, if the tool was held "north and south."

New Telegraphic Code. "The K. K. Complete Code" is the title of a new telegraphic code by W. J.

Sutherland, published in London by Messrs. Eyre and Spottiswoode, and in New York by Messrs. E. and J. B. Young and Co. The system on which this code has been compiled is said to be a great improvement on all its predecessors, and will be found most useful to people having a large amount of telegraphing to do.

Milan. The Societa Generale di Elettricit  of Milan announce an increase of 117 incandescent and 64 arc lamps. This company had installed over 11,000 incandescent lamps, and 210 arc lamps. A profit of 132,342f. is shown to the end of 1887, and a dividend of 10f. per share of 250f. has been declared. The dividend for the previous years had been of 4f. and of 7f. respectively, and the present year shows a continued increase of success.

Admiralty. In the presence of officers from the Admiralty, trials of the torpedo and electrical fittings of the undermentioned vessels will be made in accordance with the following programme:—"Belleisle," search light and torpedo fittings, June 22. With the search light only:—"Thames," June 22; "Spider," 25; "Sandfly," 25; "Raccoon," 26; "Undaunted," 29; and "Serpent," July 2. Internal lighting:—"Thames," June 23; "Raccoon," 27; and "Serpent," July 3.

The Radio - Micrometer. The radiomicrometer, invented by Mr. C. Vernon Boys, F.R.S., consists of a small thermo-electric element, formed of a bar of antimony and bismuth, of small sectional area, the ends being formed by a loop of copper wire, suspended by a torsion fibre in a strong magnetic field. It is possible to observe by its means a difference of temperature of one ten-millionth of a degree centigrade, or, more graphically stated, will indicate the heat from a single candle at a distance of one mile.

Distribution of Power. The distribution of steam by pipes to various factories is a recognised business in New York. Mr. Albert Gray, who has a large connection in this way, has established a similar distribution of power by means of electricity, and has a plant with a capacity of 450 h.p. at work on the water-side, of which he is supplying 280 h.p. to 80 customers for use with motors. He is erecting a further plant capable of distributing 1,500 h.p., as the demand is increasing far beyond his present capacity.

Electromotive Force of Lightning. Prof. Weber has been making some experiments with lightning with two insulated conductors, connected to 400 collecting points, on the summit of the Riesengebirge. The current, measured with a galvanometer, varied generally between 0.07 to 2.5 micro-amperes. The E.M.F. was judged by the length of spark, and varied from 3,000 to 10,000 volts. On quiet nights no sparks occurred. The potential rose during disturbances to 11,000 to 20,000 volts, with a current of 4 to 8 micro-amperes.

Motors in Berlin.—Several central stations are at work in Berlin, and these are now beginning to appreciate the advantage of being able to supply power for small motors during the daytime. The price varies according to circumstances. The average prices for the supply of 3,000 hours a year is as under: for motors of

1 2 3 5 8 and 12 h.p.

[0.38. 0.72. 1.05. 1.70. 2.64 and 3.98 marks per hour.

The use of these motors—especially those of smaller size—is very rapidly increasing.

Personal.—Mr. J. R. Williamson, A.M.I.C.E., who has up till now been manager of the Manchester Edison Electric

Light Company, and under whose auspices the company has attained its present position, has been elected by a special motion of the directors to a position on the Board, and on taking his seat was unanimously elected managing director. We congratulate Mr. Williamson upon the esteem in which he is held, and trust the progress made in Manchester and district by this company will be increased under his more active guidance.

Catalogue Received. We are in receipt of a catalogue of electrical fittings, very fully and neatly got up, from the General Electric Apparatus Company (Bunschwanger and Company), 5, Great St. Thomas Apostle, E.C.1., containing descriptions and illustrations of all electrical necessities that they can supply—from electric bells to steam engines, primary batteries and electric jewellery to dynamos and accumulators. Several specialties are included, and a general view of the present state of electric industries can be obtained in this agency catalogue.

Langham Hotel.—The whole of the cables and wires, as well as the switches and electroliers, &c., for this large installation were specially made for this installation, and the whole of the work has been completed in four months, and considering the thorough character of the work, it may be said to be one of the quickest installations recorded in the electrical world. The work was carried out under the direction of Mr. J. Elwin Coles, the manager, and Mr. J. G. S. Cunningham, the electrical engineer of Messrs. B. Verity and Sons, of King street, Covent Garden, not Messrs. Verity Bros., as stated in our last issue.

Bogey. We once heard a parson give as the reason why he did not take his text so that he could sermonise upon familiar topics, that if he did so, some specialist of the congregation would surely take him to task for not better understanding Nature's connection with science. He admitted he knew nothing of scientific progress or scientific views, and we suppose the same applies in the case of the "British Association of Medical Electricians," so far as the selection of president is concerned, for we have yet to learn that Mr. C. B. Harness, who has been elected to this position, is an electrician, medical or otherwise.

Folkestone. The Folkestone Corporation at the last meeting discussed the report of the Electric Lighting Committee upon the subject of lighting the Leas by electricity, and as to entering into a contract with Messrs. Laing, Wharton, and Down, or any other firm for that purpose. Mr. Logan moved the adoption of the report, which was seconded by Mr. Payer. Mr. Thompson moved as an amendment that the report be referred back to the committee, with a view to modify their scheme. This was seconded, but on being put was lost—4 voting for it, and 8 against it—and the original motion was carried by 7 votes to 5.

Bath.—A private meeting of the principal citizens of Bath (who are also the largest consumers of gas in the city) was held at the Grand Pump Room Hotel on the 15th inst., when it was decided to take at once the necessary steps for the formation of a local company for supplying Bath with the electric light for private and public use. It was decided to send in a tender to the Corporation for the lighting by arc lamps of a central area, at a price that would pay 5 per cent. upon the capital employed. Mr. Massingham, who was present, promised to find £5,000 of the capital required, and also to assist the company in other ways.

More Copper.—M. Dupont, director of the Museum of Natural History at Brussels, has found evidences of large deposits of copper on the Congo on the Zassair River; so that we need not be dependent on present supplies. The Copper Syndicate, however, will be no more before this comes into the market. A very important discovery of copper is also reported to have been made near Frankford, Tasmania. It is stated that one lode, 1 ft. in width, has been struck, and that there are indications of numerous other lodes. Assays have been made both on the spot and in South Australia, and give favourable results as to copper and a fair percentage of gold and silver.

Mr. J. Willing, the Inventor.—A paragraph is going the round of the daily press, in which it is given to appear that Mr. J. Willing, jun., has patented a contrivance which enables that to be done which could not have been otherwise have been done—namely, to use the electric light on an omnibus or tramcar. We have heard of Willing, the advertiser; but Willing or Snilling, or Billing the "inventor"—never. According to these wise paragraphers, nobody has ever been able to light a car by electricity till now. We might tell them that any schoolboy could do it, if allowed the use of the necessary "storage-boxes" mentioned, by the joint action of the omnibus directors and the Electrical Power Storage Company.

New Method of Reading Reflecting Instruments. *Science* gives the following abstract of a paper by M. F. Drouin in the *Lumière Electrique*:—"The usual mirror is replaced by a thin disc of glass. The scale being behind the instrument, the observer in front sees the scale directly through the glass, while he sees reflected from the front surface of the glass the image of an object, such as a black line on a white background, placed in front of the instrument, and to one side. When the glass disc is deflected through an angle, α , the virtual image of the mark is displaced through a distance, $d \tan 2\alpha$ (d =distance from glass to scale). The method can be used in a well-lighted room, and does away with lamps and shades."

Society of Arts Conversations.—The annual conversation of the Society of Arts was held on Wednesday at the South Kensington Museum, and was largely attended. Among the guests received by Sir Douglas Galton and the members of the Council were several Indians, whose picturesque dresses add so much to the effect of these gatherings. The building was brilliantly lit up throughout, and the exhibits were seen at their best. The picture galleries were less crowded than other parts of the building, so that those guests who sought the comparative retirement of the galleries had ample time and opportunity to admire the Raphael cartoons, the Sheepshank's collection, and the new pictures which have been added to the museum from time to time.

Conscious through it all.—Superintendent Jeffries, of Lawrence (Kansas) Electric Light Company, relates his experience with a high-tension shock. When adjusting the brushes the other night, his body accidentally came in contact with the brushes, and the city circuit used his body as a conductor, and for about twenty seconds gave him such a shaking he doesn't care to have repeated. The blood was forced through the ends of his fingers, and the palms of his hands were burned. He remained conscious through it all, but was unable to move or regain his power of speech for several minutes after his release. It might be interesting to inquire how long will a Yankee prisoner be conscious

after his power of speech and movement are gone when executed under the new law.

Air Cushion.—Now that motors are being introduced for all manner of purposes, that of raising lifts will not be forgotten. We notice a trial has just been made with an air cushion for stopping lifts, which it may be well for those designing such pieces of apparatus to bear in mind. The suspension of lifts has been known to fail, and the whole has come down with a run, with disastrous or even fatal results. Several breaks or safety appliances have been proposed, but the best accident preventer seems to be the air cushion. A large lift was raised to full height, chairs and a table were arranged, a glass of water and an egg were placed upon the table, and the whole suddenly dropped, the air cushion arrangement being at the bottom. The whole came to a stop without any sudden shock, not even a drop of water being spilt, nor was the egg broken.

Rather Mixed. A German contemporary, published in Berlin, but written in English, has this week, under the heading of "Industrial," the following extraordinary description of what is evidently a small motor, as follows:—"A Diminutive Electrometer. The firm Siemens and Halske has constructed a small electrometer, which in its most diminutive size is provided with ring-like fittings and has a diameter of about 30 centimetres and a height of 18 centimetres. It has a capacity of $\frac{1}{10}$ HP., the number of its revolutions per minute is 2500, while the expenditure of electric energy equals about 150 volt-amperes. In its smallest form, this electrometer is most suitable for driving sewing machines, lathes, etc., but above all for working a silently-moving ventilator, specially constructed for this purpose by the firm, which transports 40 cbm. of air per hour."

Death by Electricity.—According to Dr. Robert Amory, who writes in the *Electrical World*, death is not caused by the shock itself, but results, as in hanging, from asphyxia. "It will be evident that if a living body is held between two conductors of opposite potentials of electrical condition, and receives the full current between a very high electrical potential to a very low potential, and cannot be extricated in time, the animal functions of muscular contraction are thrown into a strong tonic spasm, which will prevent the free respiratory movements which are essential to life. If these conditions are maintained for a sufficient period of time, the natural movements of respiration are delayed long enough to suspend the movements of blood in the capillary circulation. Thus the tissues are paralyzed, and oxidation of the blood ceases, and in consequence the blood ceases to stimulate the heart to action."

Machines for Copper Wire.—It is recorded that Mr. H. A. Williams, of the Williams Manufacturing Company, of Taunton, Mass., has invented a machine for cheapening and improving steel or iron wire, which will probably make a change in many branches of industry in which wire is used. The invention consists of a series of rolls in a continuous train, geared with a common driver, each pair of rolls having a greater speed than the pair preceding it, with an intervening friction clutch adapted to graduate the speed of the rolls to the speed of the wire in process of rolling. The entire process of manufacturing the smallest size wires from rods of $\frac{1}{16}$ in. is done cold. The new process obviates the danger of unequal annealing and of burning in the furnaces, and the wire is claimed to be more flexible and homogeneous than that produced by the common processes, and

capable of sustaining greater longitudinal strain. Copper wire made by this process is claimed to be possessed of greatly increased electrical conductivity. The Williams Wire Machine Company will manufacture the machines at Taunton, Massachusetts.

The Detection of Hot Bearings. M. Gerboz has devised an apparatus which should prove of considerable use in central station work, by which an audible and visible signal is given to the engineer if any part of the machinery to which the apparatus is fitted should become unduly heated. In its simplest form, as applied to the crank pin of a steam engine, the device consists of a small cylinder fastened to and projecting from the crank pin, and containing a plug of easily fusible alloy, which is pressed against the end of the crank-pin by a perforated piston and spring. The piston-rod, by means of a lever, controls a catch belonging to the mechanism of a bell placed over the apparatus. The gear of the bell, which is actuated by spring power, is previously wound up by hand and locked by the catch. If the crank-pin should become heated, the fusible plug melts, thus allowing the piston to descend, thereby releasing the catch and sounding the bell. In addition to this audible signal a disc, hidden underneath the bell, is turned in such a position that a bright colour is seen through two holes in the disc of the bell.

Ipswich.—A model installation has just been completed at Messrs. G. Mason and Co.'s oil mills, by Messrs. Paris and Scott, of Norwich. The details were arranged with Mr. Heaphy beforehand, the risk in oil mills being considerable, and special precautions have been adopted throughout. The plant consists of a Tangey engine of 10 h.p., fitted with a Turner-Martnell governor. This engine drives one of Messrs. Paris and Scott's new patent "C" type dynamos, which generates the electric current carried direct to each building by six cables; the seventh cable charges a set of 13 accumulators to supply the lamps in the warehouse when the engine is not running. In the works are three lamps of 200 c.p. each, forty seven of 16 c.p., and thirteen of 8 c.p. All the main and branch cables, which are of special make, are run in oak casing painted with cyanite paint, and provided with double pole magnetic cut-outs, which break the circuit if from any cause 25 per cent. more than the normal current of electricity passes, and each lamp is also protected by a fuse. The installation has in every detail been thoroughly carried out, and is a model of what such an installation should be.

Royal Meteorological Society.—The concluding meeting of this society for the present session was held on Wednesday evening, the 20th inst., Dr. W. Marcot, F.R.S., president, in the chair. Among the papers was the "First Report of the Thunderstorm Committee." This report deals with the photographs of lightning flashes, some sixty in number, which have been received by the society. From the evidence now obtained it appears that lightning assumes various typical forms under conditions which are at present unknown. The committee consider that the lightning flashes may be arranged under the following types: (1) stream; (2) sinuous; (3) ramified; (4) meandering; (5) beaded or chapletted; and (6) ribbon lightning. In one of the photographs there is a dark flash of the same character as the bright flashes, but the committee defer offering any explanation of the same until they get further examples of dark flashes. As the thunderstorm season is now coming on, the committee propose to publish their report at once, along with some reproductions of the photographs by the autotype process, in order that

observers may be prepared to notice the various forms of lightning.

The Dynamicables. What has become of the Dynamicables? It is a question many of our readers may have often asked. It was to be a social club for electrical engineers, an opportunity of meeting for those directly interested in electric light and power, and to set the tide for all affairs directly affecting the electrical engineering interests. But it seems to have been more or less swamped. The Boston Club is in a flourishing condition, with a fine building, and magnificent suites of rooms for meeting, dining, and conversation, fitted with electric light and all the newest appliances, the door even opens by itself by electricity as you enter, and a feeling of good fellowship and of commercial usefulness is apparent. Where is the analogue of this in London? Apart from the strictly proper and highly scientific circles of the Telegraph Engineers, it was easily seen that some other means of meeting and discussion were required, and the Dynamicables were to fill this field. We do not think it can be said that they have hitherto done this; but, perhaps, better times are in store. A feeling of activity is moving amongst them, and it wants one or two real live men, with the good interest of electrical circles at heart, to take the initiative for this amiable and talented society to make its influence felt.

Terni.—Our Italian electrical contemporary furnishes particulars of an interesting central station at Terni, which has been running since February last. The number of lamps at present in use is 350, of 16 and 50 c.p., distributed over a distance of 2½ miles. The central station is situated away from the town; the system in use being with Zipernowski transformers. The primary wires are seven millimetres in diameter, run overhead, and are not insulated. The generating plant consists of three sets of machines, one being for reserve. Each set consists of a 150 h.p. Gerani turbine, with a Zipernowski alternate current dynamo of 40 amperes and 2,000 volts, driven at 250 revolutions per minute, with a separate exciter giving 60 amperes continuous current at 100 volts. Each set of generators will feed 1,000 16-c.p. lamps, so that, including the reserve, the installation will be sufficient for 3,000 lamps. The regulation is effected by means of six resistances, so arranged as to set in motion and connect a second dynamo when necessary. The primary current is transformed at the town itself by means of 21 Zipernowski Dani Blathy transformers of 7,500 volt-amperes, which feed into different secondary circuits, maintaining a constant pressure of 100 volts. The installation was completed in ten months by Ganz and Co. for the "Societa della Valnerina di Terni."

Spanish Theatres.—The Spanish Government having rendered the lighting of the theatres compulsory, great efforts have been made to satisfy this obligation. The first theatre to complete its lighting on the new system is La Comedia Theatre of Madrid, where 450 incandescent lamps have been installed. Collet tubular boilers are used, with one quick-speed vertical engine and two Schuckert dynamos, giving 75 amperes at 105 volts. The management, however, got into hot water on account of the noise made by the machinery, to which the neighbouring tenants strongly object. The space available for machinery is very limited, and the installation cannot be said to be as silent as it might be. An injunction has been granted by the authorities, and the theatre, not being allowed gas, has had to fall back upon the primitive candle. Meanwhile they are still under the commands of the Government to

be properly lighted by electric light by September next. We understand that it is very probable an English company will receive some of the orders for lighting other Spanish theatres, and those installations will, we are sure, prove satisfactory. The Spanish are a peculiar nation on business matters, and should have laid their plans better in the first instance. It might be preferable, on all accounts, if the distribution were effected from a central station, with machinery in an unobjectionable place, instead of the complete upheaval of every theatre and public building in Madrid to fix a steam-engine and boilers. As gas is at nine shillings a thousand, there is evidently an opening in the town for an electric light company.

Carbon Electrodes.—In an article on "Carbon Electrodes for Secondary Cells," in the *Electrical World*, Mr. A. V. Meserole says: "Carbon has been considered an ideal substance for secondary battery electrodes, on account of its constant conductivity and indestructible nature. Common battery carbon is not at all suitable for this purpose, probably on account of the foreign matter usually combined with it. Electrodes composed of mineral or gas carbon will not absorb or retain enough electrical energy to be of any practical use in a secondary battery. There is always some local action, and when a charging current is passed through the cell large quantities of sulphuretted hydrogen gas are set free. A very fair secondary cell, however, may be made, with carbon as an active absorbent, by using certain vegetable carbonised substances, such as bamboo, boxwood, and the like, which form good conductive carbon. This may be pulverised and mixed with variable proportions of graphite, and pressed into porous pots or bags. The material should be worked into a paste with acidulated water, and then compressed within the porous retaining envelope along with a number of conducting plates or rods composed of an alloy of lead and antimony, amalgamated with mercury. The usual grid also may be filled in with this plastic material, and then closely wrapped with asbestos tape or cloth to prevent washing out. The addition of oxide of lead to the mass, forming one electrode, will increase the capacity of the element, and so would the addition of oxides of various other electro-negative and electro-positive metals to the respective secondary poles. The addition of any quantity of metal or oxide would, of course, introduce objections which the use of carbon alone is intended to avoid. The use of a pure carbon grid containing a pure carbon active absorbent would be preferable in many respects. It would have a constant conductivity, would be practically indestructible, and would permit the use of any desired electrolyte, which may be the key to future improvements in secondary batteries."

A New Form of Galvanometer. A new form of galvanometer, whose action depends upon the variable degree of expansion under the influence of heat of different metals, has been proposed. This device is well known and employed largely as a thermostat. The objection to the use of such a device in instruments of any delicacy is that they must be adjusted according to the temperature in which they are used, or some compensation must be made for the differences of position or deflection which varying temperatures cause. Dr. W. E. Geyer and Mr. W. H. Bristol, of the Stevens' Institute of Technology, Hoboken, New Jersey, have introduced a form of galvanometer on this principle, whose indication is entirely independent of the surrounding temperature. A compound arm or bar is employed consisting of but a single metal, the two arms of the bar being

joined at one end, but insulated from each other through their length. These two arms are made of such relative shape and size as to be differently heated and expanded by a current of the same strength passing in series through each. The compound bar consists of a wide strip of metal (of german silver, for instance), and of a wire of the same metal. These two pieces of metal are insulated from each other, and their free ends are connected to the binding posts, near which also they are firmly held in place so as to prevent movement at that end. A given current passing through the strips in series will raise the temperature of the wire more than the strip on account of the greater radiating surface of the latter, and the wire expanding more than the strip bends or deflects the bar, which will tend to straighten out. The gearing of the pointer on the scale is so arranged that the deflections of the pointer shall be in direct proportion to the strength of the current passing through the compound bar. Both parts of the bar are equally and similarly affected by any external changes of temperature, therefore the apparatus is independent of the surrounding temperature, and as the indication is effected by the heating effect of the current, the instrument is adapted for alternating currents as well as continuous, and in connection with suitable clockwork may act as a current register or meter.

Manchester Botanical Gardens.—The Botanical Gardens, Old Trafford, Manchester, which formed part of the late Royal Jubilee Exhibition, have been rendered more attractive by the Corporation, and have been lighted by electric light by the Manchester Edison-Swan Company, Limited. Fifty-six 2,000 c.p. arc lamps are used. The combined boiler and engine has been constructed by Messrs. Marshall, Sons, and Co., Limited, Gainsborough, and was erected by Messrs. J. B. Welch and Co., Market-street, Manchester. It is provided with Hartnell's automatic expansion valve gear, by which great regularity in speed is attained, even under considerable and frequent variation of load. The engine runs at a speed of 120 revolutions a minute, and is capable of indicating 130 h.p. Two shunt wound dynamos, specially constructed for this work by Messrs. Elwell-Parker, Limited, Wolverhampton, are used, capable of supplying forty 10 ampere arc lamps each. Switches and resistances, together with a current indicator, are fixed in the engine-room. The arc lamps used in this installation are a new and neat type of lamp—the invention of Messrs. Phillips, Harrison, and Hart. The regulating apparatus is very simple and not liable to get out of order, and the light is very steady. The building which formed the main approach to the late Exhibition has been converted into a dining room, promenade, and concert room, which are lighted by 24 arc lamps. The remaining 32 arc lamps are distributed in the grounds, and are fixed to masts. Overhead wires are used, which are hardly perceptible. The installation works very well, though a humming sound caused by the exhaust steam was noticeable, which was audible in the concert room, and ought to be remedied. This arc light installation is the largest the Manchester Edison-Swan Company have as yet erected, their usual work being incandescent lighting, but in future they intend to devote more attention to arc lighting. The whole of the arrangements in connection with the electric lighting have been carried out by Mr. J. R. Williamson, A.M.I.C.E., managing director of the Manchester Edison-Swan Company, and to his personal superintendence and unremitting exertions is due the success which has attended this most important installation of the arc light in the district.

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, B.Sc., F.R.S.R.

[All rights reserved.]

(Continued from page 584.)

INSTRUMENTS FOR THE MEASUREMENT OF ELECTRIC CURRENTS.

The instruments which may be included under this heading have become within the last few years very numerous. For our present purpose it is necessary that the general principles on which the proper construction of such instruments depends should be stated, and that a few examples of the different types should be described. Under the head of instruments for the measurement of currents, it will be convenient to include that class of voltmeters the indications of which depend on the current passing through them. The instruments now most used in the practical applications of electricity almost uniformly lay claim to be designated measurers in absolute units; but previous to this state of things there existed many valuable instruments, the indications of which depended on electric currents, which, in comparison with the more modern class, may perhaps be properly called galvanoscopes. They have generally been called galvanometers, and, as they have already been frequently referred to, are largely used, and are the most suitable, for the comparison of resistances and similar experimental work, a description of them will be taken first.

Galvanometers.—These instruments originated with the discovery and publication by Oersted of the action of a wire through which a current of electricity is passing on a magnetic needle. If the needle be pivoted or suspended in such a way as to be free to move, and a wire conveying an electric current be brought near to it, the needle tends to turn so as to place its length at right angles to that of the wire.

Fig 23.

Fig 24.

The direction, relatively to that of the current, in which the needle will move is of considerable importance in some cases, and several rules have been enunciated for the guidance of experimenters. The following is perhaps as simple and easily remembered as any other. Suppose the earth's magnetism to be due to a permanent magnet in its centre, which has been turned into position by currents round the earth's equator, then the direction of the current round the earth would be the same as that of the sun's motion. If, then, we suppose a magnetic needle suspended with its length horizontal and free to turn round a vertical axis, it will always be turned by a current towards such a position that, to an observer looking at the *true north* end of the magnet, the currents will pass from left to right over the magnet, or from right to left under it. By the *true north* end of the magnet is meant the end at which the corresponding magnetic pole to the north magnetic pole of the earth is situated that is, the "south seeking" pole of the needle. The force with which the needle is urged towards this position is proportional to the magnetic moment of the needle, to the strength of the current through the wire, to the number of times the wire passes over or under the needle, and to the proximity of the wire to the needle. Probably the earliest form of galvanometer was Schweigger's multiplier, which was invented in 1820, shortly after the publication of Oersted's discovery. It consisted of a magnetic needle, pivoted in the centre of a rectangular coil of wire, through which

the current was passed. The object of this invention was to obtain sensibility by passing the current several times round the needle, and the rectangular form was evidently intended to bring the wire near the needle, while at the same time its length could be in the central plane of the coil, or the position of maximum turning couple. The rectangular form of coil is still much used, especially in galvanometers provided with needles of considerable length. The more common form for the coil in the instruments now used for accurate work is a circular ring of approximately rectangular cross section. The action of a circle of wire conveying an electric current on a magnetic needle hung within it will be more readily understood by reference to Figs. 23 and 24, which show a plan and elevation of a ring and needle. The needle, *s n*, is suspended with its length horizontal near the centre of the ring, *R*, which is supposed to be fixed with its plane vertical and parallel to the equilibrium position of the length of the needle, *s n*, when no current is flowing through the ring. When a current is made to flow through the ring in the direction of the arrows, the needle turns into some such a position as that indicated in the figure, the exact position being determined by the strength of the current and the strength of the magnetic field in which the coil and needle are placed. Let the strength of current through the coil be *C*, and the strength of the field, or force with which a unit magnetic pole is acted on in the field, be *H*. Then, if the strength of each pole of the needle be *m*, the distance between the two poles *l*, and the angle which the length of the needle makes with the plane of the coil *θ*, we have equilibrium between the couples $A C m \times n n$ and $H m \times s a$. But $n a = l \cos \theta$, and $s a = l \sin \theta$, hence $A C m l \cos \theta = H m l \sin \theta$, or

$$C = \frac{H}{A} \tan \theta.$$

The multiplier, *A*, introduced into these equations is a constant which depends on the size and number of turns in

Fig 25.

Fig 26.

the coil or ring, *R*. The force on the poles of the needle due to the current in the ring is here supposed to be at right angles to the plane of the ring, which is only accurately the case when *θ* very small, or when the needle is very short compared with the diameter of the ring, or when a coil is used consisting of a number of rings arranged to form a solenoid, the length of which is great compared with the diameter of the rings. In sensitive instruments, it is desirable that the diameters of the rings of wire forming the coil should be small, and also that the coil should be short that is to say, the whole of the turns of wire forming the coil should be brought as close to the needle as possible. This condition is inconsistent with the production of a uniform magnetic field round the needle, and hence, if the tangent law is to be used, it is important that the maximum deflection of the needle be small. The best instruments of this class are Thomson's mirror galvanometers, which will be more particularly described presently. The difficulty as to the want of uniformity in the magnetic field produced within the coil around the needle can, of course, be got over by determining experimentally the deflections produced by measured currents of different strength and in this way calibrating the instruments. This device is very commonly resorted to with instruments for the measurement of large current or high potentials — amperometers and voltmeters — and methods of performing the calibration will be described further on.

An improved form of multiplier was invented in 1825 by

Nobili, who introduced a second magnetic needle of opposite polarity to the first into the instrument. The arrangement of the coil and needles in Nobili's multiplier is illustrated in Fig. 25. Two magnetic needles, s_n and $n_1 s_1$, are attached to a rigid rod or frame, a , and either pivoted or suspended by a fine wire, b , so as to hang with their length horizontal, and to be free to turn in azimuth. The lower needle is placed in the middle of the multiplier coil, c , and the upper needle slightly above the upper edge of the coil. It is clear from what has been said above as to the direction in which a magnet is turned by a wire conveying an electric current, that the effect of passing a current through the coil, c , will be to turn both needles in the same direction, and hence, other things being the same, greater sensibility will be obtained by the double needle arrangement. The great importance of the double needle system lies, however, in the fact that while the total effect of the coil on the needle system is the sum of its effects on the separate needles, the couple acting on the deflected needle system produced by the magnetic field in which the instrument is placed, and which balances that produced by the coil, depends not on the sum but on the difference of the couples acting on the separate needles. This is illustrated in Fig. 26, which shows a perspective view of the double needle, supposed in this case to be suspended by a fibre of negligible rigidity. The directions of the forces on the needles are indicated by the arrows in the figure. Let the strength of each magnetic pole of the needle s_n be m , and the distance between the poles l ; let the corresponding quantities for the needles $n_1 s_1$ be m_1 and l_1 ; and let θ be the angle which the length of both needles makes with the direction of maximum horizontal force H in the magnetic field. The couple acting on the needle s_n will be $H m l \sin \theta$, and

Fig. 27.

the couple acting on the needle $n_1 s_1$ will be $- H m_1 l_1 \sin \theta$. Hence, the total couple acting on the system is $(m l - m_1 l_1) H \sin \theta$. But $m l$ and $m_1 l_1$ are the magnetic moments of the needles s_n and $n_1 s_1$, respectively. Hence, it appears that if the two needles have equal magnetic moments, there will be no couple acting on the needle due to the magnetic field, and, in consequence, the needle system would turn so as to set the lengths of the needle at right angles to the planes of the coil when a current, no matter how small, is passed through the coil. When the needle system is in this condition it is said to be *astatic*. That is to say, when it is placed in a uniform magnetic field, it will be in equilibrium in any azimuth. The magnetic moments of the two needles are never absolutely equal, but the arrangement is always more sensitive than a single needle placed in the same magnetic field. A perfectly astatic system has another advantage—namely, that a change either of strength or direction of the force in the uniform magnetic field produces no deflection of the needles, and no change of sensibility. The directive force for such a case is obtained by placing a permanent magnet in such a position near the needles that it produces a somewhat stronger field at one needle than at the other. It generally happens in actual practice, however, that the system is not nearly astatic, and sensibility is obtained by producing a field of such different strengths at the two needles that it is nearly astatic. Under these circumstances, however, the

so called astatic system is sometimes particularly sensitive both to change of strength and change of direction of the uniform part of the controlling field, and hence astatic galvanometers are generally subject to troublesome changes in their zero of deflection, and also in their sensibility.

Another form of instrument for the measurement of electric currents was invented by Becquerel in 1837, and is illustrated in Fig. 27. It consisted of an ordinary weighing balance, A , from the scale pans, D and E , of which were suspended two bar magnets, s_n and $s_1 n_1$, which were acted on by two coils of wire, B and C , through which the current was passed. The current was generally made to flow through the coils in such a direction as to repel both magnets, and the force was measured by putting weights on the scale pan D . This form of balance was never much used, but it is interesting as an easy example of a species which took advantage of the force with which a coil of this form tends to move a magnetic pole along its axis. Very similar principles are involved in some modern instruments.

About this time also the sine and the tangent compasses, since so much used for absolute measurements, were invented by Rouillet, and among others of the earlier workers in the improvement of instruments for the measurement of electric currents, the names of Poggendorf, Gauss, Weber, Helmholtz, Wheatstone, Joule, and Thomson are prominent. We shall next consider some examples of the instruments now in general use.

(To be continued.)

THE TESLA ALTERNATE CURRENT MOTOR.

The interest taken in M. Tesla's contributions to electrical apparatus and to electrical literature is so great, and the subject is so important, that we do not hesitate to give further space to the subject. On May 26 a communication on the subject from Dr. Louis Duncan, of Johns Hopkins University, appeared in our American contemporary, the *Electrical Review*, to the following effect:

"We may, for our present purposes, divide motors into two classes: Continuous, in which the armature coils are unsymmetrical with respect to the poles, and which, therefore, give a practically constant torque, and alternating motors, in which the armature coils are symmetrical with respect to the poles, and which, therefore, give a torque varying both in magnitude and sign during a period of the counter E.M.F. The Tesla motor belongs to this latter class.

"In every motor the torque is equal to the rate of change of lines of induction through the armature circuit for a small angular displacement, multiplied by the armature current, or

$$\frac{d\Phi}{dt} I.$$

In the Tesla motor the first of these terms is greatest when the coil is opposite a pole and the field currents have their greatest amplitude. It is zero at a point about 45 deg. from this, supposing we neglect armature reactions. It depends on several things. The E.M.F. which determines it is due to changes in the number of lines of force passing through the armature circuit caused by (1) changes in the field currents; (2) the motion of the armature. The current depends on these E.M.F.'s, and on the reduced self-induction and resistance of its circuit. The motor can only do work when the first cause of E.M.F. is the greater, for a current in the direction of the ordinary counter E.M.F. would stop the motion. In some parts of a revolution the two E.M.F.'s work together, retarding the motion; in others, the induced E.M.F. produces a current causing the motor to revolve. It is impossible for me, with only a meagre description of the principles of the machine, to give an idea of the relative magnitudes of these effects. Some of the results, however, are the following: Having given a definite number of reversals of the dynamo, there are a number of speeds, multiples of these reversals, at which the motor will govern itself when it is doing a certain amount of work. At one of these speeds, depending on the construction of the motor, the output will be a maximum.

Now I see the statement that 'there is no difficulty what ever attendant upon starting the motor under load.' I cannot reconcile this with above facts. That the torque for a smaller number of revolutions than ordinarily used, might be greater, one can readily see, since the counter E.M.F. is less in proportion to the induced E.M.F., but it must be remembered that for certain speeds even the induced current would tend to stop the motion; how the motor is to pass these critical speeds I do not see. Again, if the maximum load is suddenly thrown on while the motor is running at its proper speed, then, if the inertia be great, the motor will fall behind its point of maximum work, and either stop or take up some slower speed.

"What the possible efficiency and output of the motor may be, only experiment can tell. I have shown* that the output of an ordinary alternating motor is equal to that of a continuous current motor, supplied with a corresponding E.M.F. The efficiency might be great, but it has the disadvantage that about the same current flows for no work and maximum work, so for light loads the efficiency can hardly be very high.

"With our present knowledge of alternating currents it is useless to attempt to calculate from the simple though misleading assumptions ordinarily made, the output, conditions of maximum work, &c., of this machine. Experiment alone can determine its value, and one properly conducted and interpreted set of experiments should enable us to judge both the merit of the invention and its best possible form. I cannot see, however, how, in the form described in the last issue of this journal, the motor can work under conditions of a suddenly varying load as satisfactorily as continuous current motors."

To the above Mr. Tesla replied on June 2 as follows:

"I find in your issue of last week a note of Mr. Duncan referring to my system of alternate current motors.

"As I see that Dr. Duncan has not as yet been made acquainted with the real character of my invention, I cannot consider his article in the light of a serious criticism, and would think it unnecessary to respond; but desiring to express my consideration for him and the importance which I attach to his opinion, I will point out here briefly the characteristic features of my invention, inasmuch as they have a direct bearing on the article above referred to.

"The principle of action of my motor will be well understood from the following: By passing alternate currents in proper manner through independent energising circuits in the motor, a progressive shifting or rotation of the poles of the same is effected. This shifting is more or less continuous according to the construction of the motor and the character and relative phase of the currents employed, and I have indicated the theoretical conditions which should exist in order to secure the most perfect action.

"If a laminated ring be wound with four coils, and the same be connected in proper order to two independent

circuits of an alternate current generator adapted for this purpose, the passage of the currents through the coils produces theoretically a rotation of the poles of the ring, and in actual practice, in a series of experiments, I have demonstrated the complete analogy between such a ring and a revolving magnet. From the application of this principle to the operation of motors, two forms of motor of a character widely differing have resulted: one designed for constant and the other for variable load. The misunderstanding of Dr. Duncan is due to the fact that the prominent features of each of these two forms have not been specifically stated. In illustration of a representative of the second class, I refer to Fig. 1, given here with. In this instance, the armature of the motor

is provided with two coils at right angles. As it may be believed that a symmetrical arrangement of the coils with respect to the poles is required, I will assume that the armature is provided with a great number of diametrically wound coils or conductors closed upon themselves, and forming as many independent circuits. Let it now be supposed that the ring is permanently magnetised so as to show two poles (N and S) at two points diametrically opposite, and that it is rotated by mechanical power. The armature being stationary, the rotation of the ring magnet will set up currents in the closed armature coils. These currents will be most intense at or near the points of the greatest density of the force, and they will produce poles upon the armature core at right angles to those of the ring. Of course there will be other elements entering into action which will tend to modify this, but for the present they may be left unconsidered. As far as the location of the poles upon the armature core is concerned, the currents generated in the armature coils will always act in the same manner, and will maintain continuously the poles of the core in the same position, with respect to those of the ring in any position of the latter, and independently of the speed. From the attraction between the core and the ring, a continuous rotary effort, constant in all positions, will result, the same as in a continuous current motor with a great number of armature coils. If the armature be allowed to turn, it will revolve in the direction of rotation of the ring magnet, the induced current diminishing as the speed increases, until upon the armature reaching very nearly the speed of the magnet, just enough current will flow through the coils to keep up the rotation. If, instead of rotating the ring by mechanical power, the poles of the same are shifted by the action of the alternate currents in the two circuits, the same results are obtained.

"Now compare this system with a continuous current system. In the latter we have alternate currents in the generator and motor coils, and intervening devices for commutating the currents, which on the motor besides effect automatically a progressive shifting or rotation of the poles of the armature; here we have the same elements and identically the same operation, but without the commutating devices. In view of the fact that these devices are entirely unessential to the operation, such alternate current system will at least in many respects show a complete similarity with a continuous current system, and the motor will act precisely like a continuous current motor. If the load is augmented, the speed is diminished and the rotary effort correspondingly increased, as more current is made to pass through the energising circuits, load being taken off, the speed increases, and the current, and consequently the effort, is lessened. The effort, of course, is greatest when the armature is in the state of rest.

"But, since the analogy is complete, how about the maximum efficiency and current passing through the circuits when the motor is running without any load? one will naturally inquire. It must be remembered that we have to deal with alternate currents. In this form the motor simply represents a transformer, in which currents are induced by a dynamic action instead of by reversals, and, as it might be expected, the efficiency will be maximum at full load. As regards the current, there will be—at least, under proper conditions—as wide a variation in its strength as in a transformer, and, by observing proper rules, it may be reduced to any desired quantity. Moreover, the current passing through the motor when running free, is no measure for the energy absorbed, since the instruments indicate only the numerical sum of the direct and induced electromotive forces and currents instead of showing their difference.

"Regarding the other class of these motors, designed for constant speed, the objections of Dr. Duncan are, in a measure applicable to certain constructions, but it should be considered that such motors are not expected to run without any, or with a very light, load; and, if so, they do not, when properly constructed, present in this respect any more disadvantage than transformers under similar conditions. Besides, both features, rotary effort and tendency to constant speed, may be combined in a motor, and any desired preponderance may be given to either one, and in this manner a motor may be obtained possessing any

* Inst. Elec. Engineers, February, 1888.

desired character and capable of satisfying any possible demand in practice.

"In conclusion, I will remark, with all respect to Dr. Duncan, that the advantages claimed for my system are not mere assumptions, but results actually obtained, and that for this purpose experiments have been conducted through a long period, and with an assiduity such as only a deep interest in the invention could inspire; nevertheless, although my motor is the fruit of long labour and careful investigation, I do not wish to claim any other merit beyond that of having invented it, and I leave it to men more competent than myself to determine the true laws of the principle and the best mode of its application. What the result of these investigations will be the future will tell; but whatever they may be, and to whatever this principle may lead, I shall be sufficiently recompensed if later it will be admitted that I have contributed a share, however small, to the advancement of science."

STEAM CYLINDER LUBRICATOR.

We herewith illustrate a lubricator manufactured by the Steam Cylinder Lubricator Company, of Manchester. The

FIG. 1.

large use of steam-power in electrical work necessitates a knowledge not only of electrical apparatus, but also of steam and gas engines and their accessories. Figs. 1 and 2 show this lubricator. In the sectional view, Fig. 2, A is the oil chamber in which works a steam-tight piston B, packed with asbestos, having screwed into its top side a hollow steel piston rod K, which works through a stuffing box. This piston rod also serves as an indicator showing the level of the oil. At the top end of the rod is a filling plug J, through which the oil is delivered into the chamber A, the oil passing through the small holes at the bottom of the tube, D is the steam inlet, H the connection to the cylinder, G the sight feed, L an air valve, M a plug which can be unscrewed and the sight feed G inserted, if required, at the other side, E is a run-off valve, and C is the base to which the lubricator is fixed.

The method of working is as follows. When the piston B is at the bottom, and the chamber filled with oil, steam is admitted through the pipe D by opening the lower valve to the under side of the piston, the area of which is larger than

the top side by the amount of the area of the rod K. This difference of area causes the piston to be raised within the cylinder, and so displaces the oil above, which finds its way out to the engine steam pipe or chest through the upper valve F, past the sight feed G and the connecting pipe H. The quantity of oil displaced can be readily regulated by adjusting the outlet valve to give any desired quantity.

THE MINIMUM POINT OF CHANGE OF POTENTIAL OF A VOLTAIC COUPLE.*

BY DR. G. GORE, F.R.S.

In this communication is described the following very simple method of detecting the influence of the minimum proportion of chlorine, or other soluble substance, &c., upon the electromotive force of a voltaic couple (*Nature*, vol. xxxviii., p. 117).

Take a voltaic couple composed of an unamalgamated strip of zinc or magnesium (the latter is usually the most sensitive) and a small sheet of platinum, immersed in distilled water, balance its electric potential through an ordinary galvanometer of about 100 ohms resistance by that of a precisely similar couple, composed of portions of the

FIG. 2.

same specimens of the same metals immersed the same moment as the other pair in a separate quantity of the same water, and gradually add to one of the two cells sufficiently small and known quantities of an adequately weak solution of known strength in a portion of the same water, of the substance to be used, until the balance is upset, and take note of the proportions of the substance and of the water then contained in that cell. In the present experiments a magnesium-platinum couple was employed.

The minimum proportions required with several substances were as follows. Potassic chloride, between 1 part in 3,875 and 4,650 parts of water, potassic chlorate between 1 in 4,650 and 5,166, hydrochloric acid between 1 in 516,666 and 664,285, and with chlorine between 1 in 15,656,500,000 and 19,565,210,000.

The proportion required of each different substance is dependent upon very simple conditions viz., unchanged composition of the voltaic couple, a uniform temperature, and employing the same galvanometer. The apparently

* Abstract of Paper read before the Royal Society, June 14, 1888.

constant numbers thus obtained may probably be used as tests of the purity or of the uniformity of composition of dissolved substances.

The "minimum-point" varies, with—1st, the chemical composition of the liquid; 2nd, the kind of positive metal; 3rd, to a less degree with the kind of negative metal; 4th, the temperature at the surface of the positive metal and at that of the negative one; and 5th, with the kind of galvanometer employed.

The order of the degree of sensitiveness is manifestly related to that of the degree of free chemical energy of the liquid, also to the atomic and molecular weights of the dissolved substances, and to the ordinary chemical groups of halogens. The greater the degree of free chemical energy of the dissolved substance, and the greater its action upon the positive metal, the smaller the proportion of it required to change the potential.

As the "minimum point" of a chemically active substance dissolved in water is usually much altered by adding almost any soluble substance to the mixture, measurements of that point in a number of liquids at a given temperature with the same voltaic pair and galvanometer will probably throw some light upon the degree of chemical freedom of substances dissolved in water.

ON THE CHANGE OF POTENTIAL OF A VOLTAIC COUPLE BY VARIATION OF STRENGTH OF ITS LIQUID.*

BY DR. G. GORE, F.R.S.

This paper contains a series of tables of measurements of the E.M.F. of a voltaic couple composed of unamalgamated zinc and platinum in distilled water, and in aqueous solutions of different strengths of the following substances: Potassic chlorate, potassic chloride, hydrochloric acid, and bromine. The measurements were made by balancing the potential of the couple by that of a suitable thermo-electric pile (Birm. Phil. Soc. *Proc.*, vol. iv., page 130) through an ordinary astatic galvanometer of about 100 ohms resistance.

The following are the minimum proportions of those substances required to change the potential of the couple in water: Potassic chlorate, between 1 in 221 and 258 parts of water; potassic chloride, between 1 in 695,067 and 1,390,131; hydrochloric acid, between 1 in 9,300,000 and 9,388,185; and of bromine, between 1 in 77,500,000 and 84,545,000 parts.

With each of these substances a gradual and uniform increase of strength of the solution, from the weakest up to a saturated one, was attended by a more or less irregular change of electromotive force.

By plotting the quantities of dissolved substance as ordinates to the electromotive forces as abscissæ, each substance yielded a different curve of variation of electromotive force by uniformly increasing the strength of its solution, and the curve was characteristic of the substance. As the least addition of a foreign soluble substance greatly changed the "minimum point," and altered the curve of variation of potential, both the curve and the minimum proportion of a substance required to upset the balance of the couple in water may probably be used as tests of the chemical composition of the substance, and as means of examining its state of combination when dissolved. By varying the strength of the solution at each of the metals separately, a curve of change of potential was obtained for each positive metal, but not for every negative one.

INFLUENCE OF THE CHEMICAL ENERGY OF ELECTROLYTES UPON THE MINIMUM POINT AND CHANGE OF POTENTIAL OF A VOLTAIC COUPLE IN WATER.*

BY DR. G. GORE, F.R.S.

By means of a zinc platinum voltaic couple in distilled water, with its electromotive force balanced by that of a suitable thermoelectric pile (Birm. Phil. Soc. *Proc.*, vol. iv., p. 130), the effect of several groups of chemical substances upon the potential of the couple was examined. Measurements were made of the electromotive forces of a series of strengths of solution of each substance, and the results are given in a series of tables.

The minimum proportions of substance required to change the potential of the couple in water were as follows:

Potassic iodate, between 1 in	443 and	494
" bymate " 1 "	344 "	384
" chlorate " 1 "	221 "	258
Potassic iodide, between 1 "	15 500 "	17 222
" bromide " 1 "	66 428 "	67 591
" chloride " 1 "	695 067 "	704 540
Iodine, between 1 "	3 100 000 "	3 521 970
Bromine, " 1 "	77 500 000 "	81 545 000
Chlorine, " 1 "	1 264 000 000 "	1 300 000 000

On comparing these numbers we find that the proportion of substance required to upset the voltaic balance was largest with the oxygen salts, intermediate with the haloid ones, and least with the free elementary halogens. It was smaller the greater the degree of chemical energy of the substance, thus it was about 100 times less with chlorine than with iodine. And it was smaller the greater the degree of freedom to exert that energy; thus it was about 5,416,000 times less with free chlorine than with potassic chlorate, or 1,570,000 times less than with the combined chlorine of the chlorate; and about 185 times smaller than with potassic chloride, or 88 times less than with the combined chlorine of that salt.

The order or curve of variation of potential by uniform increase of strength of the solution was different with each substance, and was apparently characteristic of the body in each case. A great number of such representative curves might be obtained with a zinc platinum or other voltaic couple in different electrolytes.

POLICE REGULATIONS FOR THEATRE LIGHTING IN PARIS.

CHAPTER I.—Preliminary Formalities.

ART. 1. Every person wishing to install the electric light in a theatre, music hall, or other similar public building under the police authority, must make the declaration thereof to the Prefecture of Police.

The following details must accompany the notice:

- A detailed plan in triplicate indicating the positions of the generators, steam, gas, or air engines, the dynamo machines, batteries, accumulators, and the position of the conductors.
- A note describing the engines, giving their horsepower, and the dynamos and lamps, arc or incandescent, giving their number and candle power.
- A sample of each of the conductors, with a detailed description of arrangement of the circuits, the nature and diameter of the conductors, and the current they are to carry.

ART. 2. The work cannot be commenced until the Administration have notified to the declarer whether there are or not any modifications to be introduced into the plans deposited.

ART. 3. The electric light will not be allowed to be put into ordinary use until after it has been favourably passed by the Superior Commission of Theatres, and until after a trial lighting has been made before the Technical Commission.

ART. 4. After reception of the machinery, no modification may be made in the installation without the same formalities.

CHAPTER II.—Boilers, Engines, and Smoke Flues.

ART. 5. Steam engines, gas engines, or air engines must not be placed in parts of the building accessible to the public or to the artists. The engines must be fixed in such a manner as to afford thorough security against accidents.

ART. 6. The boiler furnaces and the fuel for the same must be placed in a separate locality, built in completely fireproof materials, with iron doors, and separated from the other parts of the establishment by walls of masonry, as well as by vault, or iron girders covered with bricks of a sufficient thickness.

* Abstract of Paper read before the Royal Society, June 14, 1888.

These localities must be well arranged and properly ventilated, either naturally by air currents issuing away from the public ways, or by flues sufficiently isolated from the other parts of the establishment, or by mechanical means.

ART. 7. The fixing of the boilers must conform to the regulations of the public administration already in force.

ART. 8. The smoke flues must be in brick, of a width and section sufficient to carry the smoke of the furnaces to which they lead. They must always be fixed 16ft. (five metres) above the tops of the neighbouring chimneys.

These smoke flues must be placed at the exterior of the building, in the courtyards or areas, unless with special permission after notice to the Superior Commission of Theatres. In any case these chimneys must not produce dense or disagreeable smoke. Either efficacious smoke consuming apparatus must be used or smokeless fuel.

CHAPTER III. Batteries, Accumulators, and Dynamos.

ART. 9. Electric batteries, or accumulators, must be placed in a special room, well ventilated, and where any noxious vapours are given off must be placed under a cover with chimneys for carrying off the gases and vapours to above the roof. The acids and other chemicals used for maintenance must be stored in a special compartment, and must never be within reach of strangers.

ART. 10. The dynamos must be placed in a dry position, not containing any inflammable matter, and protected from dust. They must be properly insulated, and kept always in good condition.

The installation must be perfectly secure in all respects. Special arrangements must be taken in the case of alternating currents.

The maintenance must be carried out by experienced superintendents and workmen.

Regulations and cautions must be posted up in a prominent position in the dynamo-room.

CHAPTER IV. Cables and Conducting Wires.

ART. 11. All conductors in the engine-room must be solidly supported, well in view, marked, and numbered.

ART. 12. The switches employed to direct the currents must be manufactured with care, and mounted on incombustible insulating material.

ART. 13. A voltmeter and ampere-meter for each machine must be mounted in a firm position to control the currents.

ART. 14. A main fuse must be placed on each cable at its junction with the switchboard. Each branch main or sub-main must be equally protected with a fuse.

These fuses must be properly gauged, and must not allow a larger current to pass at the maximum than thrice that of the normal strength.

ART. 15. In every part of the circuit the diameter of the conductors must be so proportioned to the strength of the current, that it cannot produce at any point a degree of heating dangerous to the insulation of the conductors, or to objects in the vicinity.

ART. 16. For continuous currents, the difference of potential must not exceed 300 volts at the terminals of the machines, or at the entrance of the theatre, if the source of electricity is exterior.

With alternating currents, four arc lamps at the most may be placed in series, or a number of incandescent lamps corresponding to the same potential.

Exceeding these limits, special permission must be granted by the Superior Commission of Theatres.

ART. 17. The employment of water and gas pipes or metal fittings as conductors is rigorously forbidden.

ART. 18. The wires and cables must be covered with a material offering every guarantee as to quality of the insulation: at all times the loss in the conductors through defect of insulation must be less than one-thousandth of the current carried by them.

ART. 19. Except in the vicinity of the lamps, all the wires and cables must be firmly fixed and kept a space of 10 millimetres ($\frac{1}{2}$ in.) apart at the least for incandescent lamps, and of 20 millimetres ($\frac{3}{4}$ in.) for arc lamps, the distance between the wires and pieces of metal of the building

must be 60 millimetres (1 $\frac{1}{2}$ in.), unless the cable is covered with lead.

ART. 20. When the conductors go through floors, stairs, walls, or partitions, or when they cross each other, they must be protected by a second covering of some hard and incombustible material. In situations exposed to damp, or in going through walls, special precautions must be taken to protect the conductors.

ART. 21. All wires which will be within reach of the hands of the public, or of persons not belonging to the service, must be placed under easily recognisable mouldings.

CHAPTER V. Lamps.

ART. 22. Naked lights are prohibited.

ART. 23. Arc lamps must be protected by glass globes or by lanterns. They must be provided with a wire net to catch sparks or pieces of glass.

ART. 24. Incandescent lamps of more than 30 c.p. must also be protected with a net.

ART. 25. Cables for suspending the lamps must be incombustible and independent of the conducting wire. The said wires must never, in any case, serve for suspending the lamps.

CHAPTER VI. Passage Lighting.

ART. 26. If the lighting of the passages is provided by the electric light, it must be assured by means of at least two independent batteries of primary cells or accumulators. In this case, the cables or wires conducting the current to the passage lamps must always be placed in front of the drop scene; and, further, these batteries must always be charged before the period of performance. During the period of performance the batteries must be completely disconnected from the dynamos.

The switches for connecting the batteries of accumulators to the dynamos must be placed in an open and easily accessible place, and must be provided with a plan indicating clearly the arrangement adopted for disconnecting the dynamos during the period of performance.

The batteries of accumulators or primary cells must each feed to an upright, placed one near the entrance hall and the other the pit; the branches from these uprights must cross at each landing, so that at each landing the successive passage lamps may be fed alternately, the one by the stage battery, and the next by that of the pit.

In the direction of each exit there must be placed a lamp bearing a special mark, which, for these installations, may consist of a double-power lamp, or two lamps in conjunction.

Further, all passage lamps must throughout bear a special mark, to enable those in charge to exercise an easy supervision over the lighting of the passages of all theatres.

The passage lamps must always be at least equal to five c.p.

CHAPTER VII. General Arrangements.

ART. 27. From the date that the installation of the electric light in the theatre has been passed by the Superior Commission, all communication with the gas companies' mains must be cut off.

ART. 28. Theatres, music-halls, and other similar public buildings already lighted with electric light whose installations do not conform to the present ordinances, must satisfy the same within a period of six months.

ART. 29. Article 39 of the ordinance of 16th May, 1884, and the whole of the ordinance of 21st February, 1887, and also any other ordinance contrary to the present, are hereby rescinded.

ART. 30. The present ordinance must be printed, distributed, and posted up in Paris, and in the various police stations.

Everyone whom it may concern, the Chief of the City Police, the Principal of the City Laboratory, the Commissioners of Police, and other officers of the Prefecture of Police, are charged to see that this ordinance is carried out.

The Colonel of the Sapeurs Pompiers is requested to assist therein.

H LOZE, *Prefect of Police.*

THE ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. *Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. Special Terms for a series can be arranged on application.

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:

	3 months.	6 months.	12 months.
United Kingdom.	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, *and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we gave that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

PATENTS.

It used to be supposed that a patent, in order to be valid, must possess some originality; but it may, perhaps, be taken for granted that the only danger in the path of a patent now is, that it may be disputed. Almost anything can be patented, and if it is worth nobody's while to dispute the patent, it remains and runs the usual course. We have been somewhat surprised to find the most eminent authorities advising that, for example, a patent to use motors on tramways in series controls all patents for series tramway work. Now, so far as we know, there are only three ways of working, series, parallel or multiple series, and, according to the legal wisdom, anyone patenting one or other, or all these systems, will control electric traction wholly or in part. If electric traction or transmission of power is possible, it is possible in these three ways, and this fact is well known to every schoolboy who dabbles in electrical matters. Surely, the mere fact that a man embodies this common knowledge in a patent should not be sufficient to give him a legal status whereby he can stop any other person using apparatus that it is well known can be used in these ways. Can a man patent the driving of a tramcar with one horse, or with two, three or more abreast, or two, three or more tandem fashion? Everybody knows that a carriage or tramcar can be so moved, and certainly, according to the dicta of those learned in the law, a patent taken out to the above effect in the early days of tramway work would have controlled the whole system, except, indeed, that some other wise individual would have patented traction by means of mules or donkeys. Till quite recently the engineers who have had most experience in tramway work have more or less held aloof from active participation in the schemes for the application of electricity to such work, but we are only stating open secrets by saying that one or two exceedingly strong syndicates have been formed, not to pretend to apply electric traction, but to tackle the problem and successfully solve it. The men who have taken up the work hold so commanding a position and have made tramway work so much a speciality, that they cannot permit themselves even to think of failure. Their reputation demands success, and they have sufficient knowledge to know that they are not attempting the unattainable. One of these syndicates has been examining into the Short series system as described in our columns a few weeks since, and it is because the syndicate has been advised by the most eminent legal authorities that Short's patent controls the use of motors used in series for tramway work that we call attention to the position. The question is not so much whether the series system is all that its supporters imagine as whether a patent of the kind should be accepted. Other engineers may hold that it is invalid, but to

prove it so will require a costly law suit. Further, if it is permissible to patent series working for transmission of power in tramway work, is it not permissible to patent series working for transmission of power in factories and workshops, when machines, not tramcars, are to be operated? or does the Short patent control this class of work also? Too often the patenting of a well-known device is the outcome of sheer ignorance. Men who know nothing of the subject hear of possibilities in electrical work, commence the study of the subject, do something, or make something not illustrated or described in the text-books before them, and rush to the Patent Office to secure a patent. Once in a thousand times the result may be satisfactory, but usually it leads to trouble and litigation.

PATENTS AND BALANCE SHEETS.

Those who have carefully studied the progress of limited liability and the exploitation of patents know that outside criticisms as to the value of patents are often incorrect. In the preparation of balance sheets much more has to be considered than the time during which a patent has to run. If this were the only consideration, a constant depreciation of between 7 and 8 per cent. calculated upon the original outlay would, upon the expiration of the the patent, wipe out the cost from the balance sheet. It must always be remembered, however, that the value of the business founded upon the working of patents should at any rate for a few years be a progressive one. The real question to be considered is whether or not too great a sum has been paid for the patents; if not, the progressive value of the goodwill of the business should about equalise the depreciation that should be written off against patents. Thus the amount shown upon the balance sheet might well be a constant, and at the expiration of the patents might well be taken to represent the goodwill of the business. The great difficulty to be encountered is from the fact that at the expiration of the patent anybody can enter into the business, and frequently some of the men who have learnt at the expense of the company, and know the *clientèle* of the company, do set up in business for themselves, taking away some of the clients, and competing for new business. Such competition reduces the value of the goodwill, and therefore if the money paid originally for the patents was too great, the due balance above referred to will not be kept. It is difficult to appraise the true value of any patent at the time of patenting, but a fairly simple calculation at the expiration of the patent will show what it should have been if our contention is correct. A similar chain of reasoning holds good in the case of private firms. Here a patent is generally the outcome of experimental work, and the

whole cost of that experimental work, as well as the cost of the patent, should be charged against the patent. It would be best and safest in all cases to be able to put the value of goodwill in a balance sheet as *nil*; but it will be seen that in the majority of cases this would be placing too great a strain upon the profits of the first fourteen years, whereas the fact is indisputable that a good paying going concern always has its market value—that is, always commands a price for goodwill. This market value is the exact value which has replaced the estimated value of the patents. Every rule has its exceptions. The United Telephone Company, for example, is in the peculiar position of expecting to be troubled at the expiration of its patents by Government interference, hence is in a position wherein the ordinary laws affecting business are inoperative. The result may be to give a fictitious value above or below, as the case may be, the true value of the shares. Under ordinary conditions the true policy in working a patent seems to be to make all possible clients friendly inclined by producing the best materials at the cheapest rate, thus warding off danger from excessive competition, there being no reason why an old and well-satisfied customer should leave the firm he has been dealing with and go to a new one.

MR. VERNON HARCOURT'S NEW PHOTOMETER.

The holophotometer has been designed in order to get rid of two difficulties connected with other methods of attaining the same object—viz., to measure the light emitted in every direction by any luminous source. These difficulties are—(1) The movement of the light to be measured or of the standard lamp, neither of which is desirable. (2) The errors caused in the measurement of lamps provided with reflecting fittings, by the assumption that the flame is the zero point from which measurements should be made, whereas, strictly speaking, the principal focus formed by the reflector should be taken as the zero point. Inasmuch, then, as this focus may be several inches away from the flame, and as the length of bar usually employed is 60 in. it is evident that serious errors may be introduced by the difference between the real and the assumed zero point. To establish the existence of such an error, and to eliminate it, two things are necessary—viz., that readings should be taken with bars of various lengths, and that the length of the bar should be very great compared with that between the real source of light and the focus formed by the reflector. Both these points are secured by the use of the holophotometer. The instrument is mounted upon a table capable of being moved nearer to or further from a fixed table containing a graduated bar with a movable disc (say, of the Letheney pattern), and having a standard lamp fixed at the zero of the bar. The lamp to be measured is mounted upon, or is in rigid connection with, the movable table, and is, therefore, not moved during a series of readings.

The holophotometer consists of an axis working friction-tight in a collar supported by a vertical pillar. The axis is accurately fixed at the same height and in a line with the centre of the disc. At the end nearest to the disc is placed a large mirror with its centre concentric with the axis, but so arranged that the plane of the mirror may be inclined and clamped at any angle to the axis. At the other end of the axis is fixed a telescopic arm carrying a smaller mirror, which is capable of being turned into any required position, the arm being rigidly fixed to the rotating axis of the instrument, to which is also attached the larger mirror. It follows

that the rotatory motions of the mirrors about the axis are identical. The angles of rotation are measured by the indications upon a divided circle attached to the moving axis, which are shown by a pointer fixed to the upright support.

The mirrors are adjusted in such a way that the light from the lamp to be measured falls upon the smaller mirror, thence is reflected on to the larger one, and finally along the axial line of the photometer disc. As both mirrors rotate together, it follows that if a horizontal beam is reflected correctly, all other beams will find their way along the axis of the photometer. If, therefore, the arm carrying the small mirror be moved through various angles, it will receive the light emitted from the lamp at those angles, and the light will at every angle be transmitted along the axis of the photometer. The divided circle is made large enough to serve as a complete screen of all direct light, and only the light falling on the small mirror can find its way to the disc. In order that absolute as well as comparative tests may be carried out, only one additional measurement need be made. The direct horizontal light is measured without the interposition of the holophotometer (which is mounted so as to be easily moved out of the direct line), then the mirrors are interposed, and a new measurement made. The additional path travelled by the light is allowed for in calculation, and thus the absorption of the mirrors is found, once for all, for the particular character of light under measurement. It is only necessary afterwards to multiply subsequent values by this coefficient of absorption in order to obtain absolute measurements at various angles.

The employment of mirrors in photometry has sometimes led to serious errors, but it will be seen by the foregoing description that, inasmuch as the relative angle of the mirrors is never changed, and as their absorption is easily calculated and allowed for, the only objections to their use have been guarded against and avoided.

In order to eliminate the second source of error mentioned above—viz. that arising from the formation of a principal focus—it is only necessary to take a series of readings with the table in one position, and then move it to a greater distance and take another series. If a focus is formed at a sufficient distance to produce an appreciable error, it will clearly appear in the difference between the readings at the two distances, and then it is only necessary to wheel the table to such a distance that the discrepancy is inappreciable. In other words, this is equivalent to using a bar of sufficient length to make it practically infinite compared with the distance between the focus and the real source of light.

The instrument has been designed specially for use in lighthouse work, where it becomes of the highest importance to measure accurately the total light given by any lamp, and not only that emitted in any one direction, which may or may not be the maximum.

Preliminary experiments made with the instrument by Mr. Stepany Rawson, at the works of the Woodhouse and Rawson Electric Manufacturing Company, have shown what a valuable instrument it is for the determination of the commercial value of various lamps, as well as for assisting in the many difficult problems of the diffusion and reflection of light. The absorption of the two mirrors used is, as already mentioned, stated to be only 1.8 per cent.; but a series of experiments are to be made upon this point.

A PRACTICAL METHOD OF CALCULATING AND DESIGNING DYNAMOS AND MOTORS.*

BY FRANCIS B. CROCKER.

It has happened that a large part of my work for the last three or four years has involved the designing and calculating of the proportions and constants of dynamos and motors, and I have naturally collected a number of methods and ideas relating to this subject which may be interesting and useful to others working in the same field. The methods and views which have been selected are those which I have found by experience to be the simplest and most generally

applicable, and at the same time more than sufficiently accurate for most practical purposes.

Almost everyone interested in electricity has seen the articles by Hopkinson, Kapp, and others, usually entitled the "Predetermination of the Characteristics of Dynamos." These papers are certainly very able and complete as mathematical feats; but I will venture to say that very few ever actually read those articles through, and still fewer persons understand them. This is a fact—not because there are not a great many who are perfectly capable of understanding such articles, but because the latter are so long and complicated, and so bristled with Greek letters and the calculus, that they are very uninviting, to say the least, and ninety-nine readers in a hundred turn to more attractive parts of the book or paper.

In comparison with such elaborate mathematical structures my methods seem very thin and transparent. But as most of us have neither the time nor inclination to use the complicated methods, and as articles and books generally treat the subject in that way, I think a little time may be spent profitably upon the simpler methods, even though some of them may be known to you already.

General Principles. In the first place let us consider briefly how a dynamo generates electric current and how a motor develops mechanical power. There are various ways of looking at the generation of current in dynamos, the ordinary one being the cutting of magnetic lines of force by an electric conductor. This view is very satisfactory in most cases, but I think it is very often too narrowly considered. For instance, take the old-fashioned Siemens I armature. There is no cutting of lines of force in the ordinary sense, the conductors are not really in the magnetic field at all, they first surround the lines of force, then leave them, then surround them again in the opposite direction, and so on. I think the best way is to consider the conductors as cutting so many lines of force, which also means enclosing so many lines of force, which alternate or change in intensity so many times per second. In describing the calculations of E.M.F., I will treat this subject further and give the actual values of the different quantities involved.

Development of Power by Motors. An electric motor develops mechanical power in exactly the opposite manner to the generation of current by a dynamo. In a dynamo, as we have just seen, the conductor is made to revolve in a magnetic field, and the current is produced in that conductor.

In a motor a conductor carrying a current and placed in a magnetic field is caused to revolve by the action of the magnetic field upon the current. In short a dynamo is a perfectly reversible machine, capable of converting mechanical power into electric current, or electric current into mechanical power, just as the use to which it is to be put requires. Identically the same machine can be used for both purposes, and except for the mere question of detail and convenience, there is no necessity whatever for even modifying the design of the machine to apply it to one purpose or the other. A few years ago it was not generally admitted that the best dynamo is the best motor, but now I think this fact is generally recognised. The experiments of Hopkinson and others on the efficiencies of identical dynamos and motors gave substantially the same results for both.

I will now take up and consider separately the parts of dynamos and motors.

The Armature.—The armature is the most important element of the machine, and is by far the most difficult to correctly design and properly construct.

There are two general types of armatures, the "ring" and the "drum." The ordinary Gramme ring is the best and simplest example of the ring armature, and I have always found, in studying or explaining a dynamo or motor, that this form of armature is more easily understood, and the magnetic and electric actions which take place are more apparent. The general principle of the construction of the Gramme ring is illustrated in Fig. 1, in which A is the armature core and B the winding. The advantages of the Gramme ring are: First, the diameter can be increased indefinitely without necessarily increasing the length of each convolution; and, for most purposes, a

* Paper read before the New York Electrical Society.

large diameter of armature is, in my opinion, very desirable. Secondly, the convolutions forming the winding of a Gramme ring do not cross each other, and, consequently, there is less liability to short circuits. The disadvantages of the Gramme ring are. First, the crowding together of the wire on the inside of the ring, owing to the fact that the inside circumference is, of course, less than the outside, and, secondly, the mechanical difficulty of carrying or supporting the wire, due to the fact that the wire is interposed between the iron ring and the shaft.

The ordinary form of drum armature is the Siemens, the general principle of which is shown in Fig. 2, and which is the type most generally adopted by the best makers of dynamos at the present time. For the sake of simplicity only two convolutions of winding are represented. The advantage of the Siemens armature is its solid mechanical construction, the iron armature core being mounted directly upon the shaft. The disadvantages are. First, the small diameter which we are obliged to use in order not to increase the length of the wire across the ends, which is usually considered to be dead or useless wire. Secondly, the piling up of wire on the ends where the convolutions cross each other. There are, of course, various forms of armatures, and some which do not even come under the two classes which I have spoken of, but it would only confuse the subject to attempt to consider all the forms, and if the two most typical and common forms are clearly understood, it is a comparatively easy matter to apply the principles to any other machine.

Electromotive Force. The E.M.F. which a given armature is capable of developing may be calculated or predetermined without trying it experimentally. It may also, of course, be tested by actual trial in various ways. There are also

FIG. 1 AND 2. Methods of Motor Construction.

several different ways of calculating the E.M.F. These are generally over-complicated and abstruse, and is the most difficult part of the mathematical analysis of dynamos, of which I have already spoken. A very simple method of calculating the E.M.F. in any given case, and one which I have found to give excellent results in a number of cases, is as follows:—

Let us take a typical machine, such as is shown in Fig. 3, for example, in which A is the armature core, B the exterior and B' the interior portion of the winding, N and S the pole pieces, CC the field magnet, DD the field magnet coils or winding, and E the yoke. Assuming the radial thickness of the ring to be 1 in. and its length, parallel with the shaft, to be 3 in., then the cross section of one side of the ring will be three square inches. Now, in calculating the E.M.F. we can only take one side of the ring, because the two sides are in multiple arc and do not add their E.M.F. to each other, but merely unite and flow out together at the brushes. I have found by repeated experiments that each convolution generates from $\frac{1}{100}$ to $\frac{1}{1000}$ of a volt per square inch of armature core, with 1,000 reversals per minute. This is entirely independent of the length of the convolution. The outer convolution generates no more E.M.F. than the inner: the area of the core alone determines the E.M.F. produced. If we double this area we double the E.M.F., other things being equal.

I assume 1,000 reversals per minute as a standard case; it is easy to remember, and it is not very far removed from the number which actually takes place in practice. One thousand reversals is equal to 500 revolutions in a 2-pole machine, because in one revolution the armature core passes once under the north pole and once under the south pole.

I use the term "reversals" instead of "revolutions" because it is general. For example, in a multipolar machine of 4 poles there would be four reversals per revolution. Now, in the machine we are considering, there are 3 square inches of armature core on each side, and assuming 1,500 revolutions per minute, or 3,000 reversals, and assuming 300 convolutions of wire on each half of the ring,

we will have $\frac{3}{100} \text{ (volt)} \times 3 \text{ (sq. in.)} \times \frac{3,000}{1,000} \text{ (reversals)} \times 300 \text{ (convolutions)}$, or, $\frac{3}{100} \times 3 \times 3 \times 300 = 81$ volts as the E.M.F. produced in this particular case. I assume, of course, that the armature core is saturated, or nearly saturated, magnetically. If it is only half saturated, then the E.M.F. will only be one half of 81 volts.

In the case of the Siemens armature, the cross section to be used in this calculation is the full cross-section of the armature core, because each convolution passes entirely round the core. Therefore, if we have a core 5 in. in diameter and 8 in. long we will have 40 square inches of cross-section; but, as in the case of the Gramme ring, we must use only half the convolutions in the calculation, because the two halves of the winding generate E.M.F.'s in multiple arc with each other and not in series. In a precisely similar manner we may calculate the E.M.F. in any machine by simply multiplying $\frac{1}{1000}$ (volt) by the cross section of the armature core in square inches, and by the number of con-

FIG. 3.—Methods of Motor Construction.

volutions in series with each other, and by the number of times that 1,000 reversals occur in one minute.

Field Magnets.—In designing the field magnet of a machine the first question to decide is the material out of which it is to be made. The latest data I have seen give the relative magnetic permeability or magnetic conducting power of different irons as follows: Cast iron, 10, malleable cast iron, 12; best wrought iron, 18. We see, therefore, that wrought iron is decidedly better than either cast or malleable cast; but in some cases considerations of cheapness or peculiarities of form may make cast iron preferable. Whenever cast iron is used in place of wrought, the cross section of the cast iron should be increased in proportion to its lower magnetic conducting power, i.e., any cast iron portion or portions of a magnetic circuit should be made at least 1½ times as large as the wrought iron portions of the same circuit. The second consideration in designing the field magnet is to make the magnetic circuit as short as possible; i.e., the cores should be made no longer than is absolutely necessary to get the required amount of wire on them.

The pole-pieces should generally be made larger than the field cores, particularly if they are of cast iron. By making the pole-pieces larger in cross-section, and covering more of the surface of the armature than the area of the cross-section of the core, we reduce somewhat the magnetic resistance of the circuit, and in most cases there is no objection to this increase in size. I do not believe, however, in covering too much of the armature with the pole-pieces, because if the extremities of the pole-pieces are brought close together there is leakage across between them. Furthermore, the neutral zone, where there are no magnetic lines of force passing into the armature, is reduced, and it becomes just so much more difficult to

set and keep the brushes at the neutral point. Each pole-piece should cover, in ordinary cases, from $\frac{1}{4}$ to $\frac{3}{10}$ of the armature.

The proportion between the cross-section of the field core and that of the armature core as given by Hopkinson, Dugald Jackson, and others, and which agrees with my own experience, is that the latter, to be 75 or 80 per cent. of the former; or in other words, the cross-section of the field core should be one $\frac{1}{4}$ or $\frac{1}{5}$ greater than that of the armature core, assuming them both to be made of the same material. If the field core be made of cast iron and the armature core of wrought iron, then the field should be at least twice the area of the armature core.

The field winding required to obtain magnetic saturation or to fully charge the magnets depends somewhat upon the kind of iron and other conditions, but I have found that it is affected very greatly by the distance between the pole pieces and the armature core, or what I call the magnetic "jumping space" that is, where the magnetism passes through the air, which is of very great magnetic resistance. If this space between iron and iron is $\frac{1}{2}$ in., it takes about 1,000 ampere feet per square inch cross-section of field core to saturate it; if the space is $\frac{1}{4}$ in., it takes about 700.

You will notice that I speak of ampere feet instead of ampere turns, the term ordinarily used. I do this because I have found that ampere feet apply to any size of magnet, whereas the ampere turns vary very greatly with different sizes of magnets. It must be obvious to anyone that an ampere-turn in the case of a magnet 1 in. in diameter will not produce the same number of magnetic units that an ampere-turn will in the case of a magnet 1 ft. in diameter; whereas a given number of ampere feet will always produce the same magnetic effect, whether they surround a 1 in. core or a 1 ft. core, provided, of course, the saturation point is not passed. To test the universal application of ampere-feet, I applied it first to the case of a $\frac{1}{2}$ h.p. motor, and then to a 500 light dynamo, both of which worked at the saturation point, and I found that precisely the same number of ampere-feet are required per square inch of cross section of field core in the one case as in the other. I have also applied it to intermediate cases, and it holds goods with sufficient closeness in all cases that I have come across. I should say, however, that I have not applied it to the case of cast iron magnets, and, therefore, cannot speak positively about them; but I suppose it would apply to them also, allowance being made for the different magnetic permeability.

Current Capacity.—The amount of current which a given size wire is capable of carrying is, I think, one of the most important questions involved in the designing and calculating of electrical machines. It is not, however, by any means a difficult mathematical problem to solve. The simple rule is that a good copper conductor should have a cross-section of from 600 to 1,000 circular mils. per ampere of current carried. The circular mils are simply the square of the diameter of the conductor in thousandths of an inch. The carrying capacity depends, of course, upon the conditions in each particular case. If the conductor is so situated that it may readily lose the heat produced in it by the current, its carrying capacity is increased. A single wire exposed to the air will carry, without overheating, much more current than a mass of conductors lying close together. This applies to thickness of winding. A field magnet coil, for example, should preferably be not more than one or two inches thick. If thicker than this, the heat is apt to accumulate very objectionably. Other things being equal, a small wire will carry relatively more current than a large one, because its radiating surface, as compared with its mass, is greater than in the case of a thick wire. If conductors are always made at least 800 to 1,000 circ. mils. per ampere, they will be right in ninety-nine cases out of a hundred. The error should be made on the safe side.

Power.—The power of a motor or output of a dynamo may be determined by calculating the E.M.F. and current capacity separately by means of the rules explained above, and multiplying the two together. The product will be the power in watts. The h.p. is found by dividing the number of watts by 746.

A static method of testing the power of a dynamo or motor is represented in Fig. 4. It consists in clamping an

arm upon the shaft of the machine so that it cannot turn, and then weighing the pull which the armature exerts with a given current. The power in foot pounds per minute is equal to the pull in pounds multiplied by 6.28 times the length of the arm in feet, and that product multiplied by the number of revolutions per minute at which the machine is intended to run.

This static method is, of course, not as perfect as the regular Prony brake test with the armature running. In the brake test the clamp (in Fig. 4) is loosened so as to give just sufficient friction to allow the machine to run at the proper speed, the power being calculated precisely as in the static test. The running test is, however, very much more difficult to carry out, because the friction has to be adjusted to exactly the right point, and it is very much more difficult to weigh the pull exerted by the armature when running at a high speed. An approximate test is infinitely better than no test at all, and there are a great many cases where one would go without making any test rather than try a running one; whereas the static way is so simple and short, and requires so little adjustment that one is not so likely to shirk it.

As a matter of fact, the static method is quite accurate for machines of high efficiency, because in a really good machine of, say, 90 per cent. efficiency, all the losses together are not over 10 per cent.; and the Foucault currents and resistance of air, which are the only losses which cannot be tested statically, are only a portion of this 10 per cent., say, half of it, and, therefore, do not affect the result very greatly. In fact, by allowing five or six per cent. for these two items the results will be almost perfectly

FIG. 4.—Methods of Motor Construction.

accurate in most cases. I am, of course, here only considering the testing of a machine at or near its full power, if it be tested statically at low powers, the errors will be increased proportionally. But certainly the results at full power are really those which it is most important to know. Any machine which is so inefficient that this method does not apply to it, is so poor that it ought not to be built at all. The time for inefficient and improperly designed and constructed machines has gone by.

This same static method of testing power which I have just described enables us also to determine the counter E.M.F. of a motor or the direct E.M.F. of a dynamo running at a given speed. The same arrangement, shown in Fig. 4, is used, and the pull exerted by the armature with a given current passing through it is weighed as before. We have— $E.M.F. \times \text{current} \times 44\frac{1}{2} = 6.28 \times \text{rad.} \times \text{Pull} \times \text{Rev.}$

$E.M.F.$ is expressed in volts; current , in amperes.

1 watt = $44\frac{1}{2}$ ft. pounds per minute.

6.28 = circumference of circle when radius = 1.

Rad. = radius in feet; Pull = pull in pounds

Rev. = revolutions per minute.

Assuming $E.M.F. = 1$ volt, and $\text{rad.} = 1$ ft., the equation becomes

$$\text{Rev.} = \frac{7.04 \times \text{amperes}}{\text{Pull.}}$$

That is, the revolutions per minute required to give 1 volt are equal to seven times the amperes in the armature divided by the pull in pounds at 1 ft. from the centre.

Let us now apply the foregoing methods to an actual example.

Example: Let it be required to design a series wound motor to give 1 h.p. at 1,500 revolutions per minute on a 10 ampere constant current circuit.

In the first place, it is necessary to choose a certain form of machine. The ring armature is well suited to small motors, because it is not, relatively, so small in diameter; therefore we will select that one as our type.

The best way to begin the calculation is to assume a certain diameter of armature which we think to be about right.

If it is found to be too large or too small we can change it, and the time spent in figuring upon the incorrect size will not be lost, for it will help us in calculating the right size. I have always found it well to work on both sides to the correct size in order to be surer of not making a mistake, and to see the effect of changing the different dimensions.

Armature. Assuming a ring armature 6in. in diameter when completed, and allowing $\frac{1}{2}$ in. on each side for winding, the iron core will be 5in. in diameter. Since the winding is $\frac{1}{2}$ in. thickness on the outside of the ring, it will be about twice as thick on the inside, owing to the smaller circumference, and allowing $1\frac{1}{2}$ in. for the shaft, &c., we find that the inside diameter of the iron core must be made $1 + 1 + 1\frac{1}{2} = 3\frac{1}{2}$ in. Therefore, the radial thickness of the iron ring *A* (Fig. 3) will be $\frac{1}{2}$ in. (on each side), since $3\frac{1}{2} + \frac{1}{2} + \frac{1}{2} = 5$. Assuming that the iron core is 2 $\frac{1}{2}$ in. long, the cross-section of each side of the ring will be $2\frac{1}{2} \times \frac{1}{2} = 1\frac{1}{4}$ square inches. The iron ring being 5in. in diameter, the half circumference will be very nearly 8in.

Since the motor is to run on a 10 ampere circuit, each half of the armature winding will have to carry 5 amperes, since in the Gramme armature the current divides into two parts. It has been stated above that 800 circ. mils. per ampere is a good figure; therefore, the size of the wire should be $5 \times 800 = 4,000$ circ. mils. Referring to a table of wire gauges, we find No. 14 B. and S. = 4,106 circ. mils., which we take. No. 14 wire is .064 in diameter naked, and allowing .012 for insulation (average allowance), we have .076 as total diameter. Therefore No. 14 will lay 13 to the inch ($13 \times .076 = .988$).

Again, since the half circumference equals 8in., one layer will require $8 \times 13 = 104$ convolutions, and as we have $\frac{1}{2}$ in. space for winding we can have 5 layers = 520 convolutions, and still space enough for clearance. Each convolution is about 7in. long ($2\frac{1}{2} + 1 + 2\frac{1}{2} + 1$), making 300ft. of wire, weighing, according to wire table, 5 pounds, on each half of armature, or 10 pounds of wire in all.

We have seen above that the volts produced by a machine = $.035 \times \text{cross-section} \times \text{convolutions} \times \text{No. of reversals}$.

Substituting the values we have in this particular case, $.035 \times 1\frac{1}{4} \times 520 \times \frac{3,000}{1,000} = 102.3$ volts. That

is to say, the counter E.M.F. developed by this motor running at 1,500 revolutions per minute will be 102.3 volts. I use .035 in this case because it is an average value; but, probably, .03, which I used before, is a surer and safer figure.

Field-Magnet Cores.—The cross-section of each side of the armature core we have determined to be $1\frac{1}{4}$ square inches, and both sides added would be $3\frac{1}{2}$ square inches. Therefore the field-magnet will have to be sufficiently large to fully saturate this area; or, as has already been stated, about 25 per cent. greater, which would make it $4\frac{1}{4}$ square inches very nearly. The diameter of core corresponding to this cross-section is 2 $\frac{1}{2}$ in. This is the proper diameter for a wrought iron core, for cast iron it should be about 70 per cent. greater cross section, or 3 $\frac{1}{2}$ in. in diameter. The yoke should be made at least equally large.

Field Magnet Winding. Since the field winding carries the whole current of 10 amperes, it should be of about $10 \times 800 = 8,000$ circ. mils. = No. 11 wire. In the case of the field winding a size larger, No. 10 is safer and better. The length of wire required to obtain saturation with a distance of $\frac{1}{2}$ in., between the pole piece and armature core is 1,000 ampere-feet per square inch area. In this case the field core is $4\frac{1}{4}$ square inches in section. Therefore, we shall need 4,750, say 5,000 ampere feet; and since the current is

10 amperes, the necessary length of wire is 500 feet, including both cores, weighing about 20 pounds insulated. The cores are 2 $\frac{1}{2}$ in. in diameter, or about 8in. in circumference; therefore, there will be $\frac{12 \times 500}{8} = 750$ convolutions, or 375

on each core. (The number 12 in the equation stands for the number of inches in a foot.) Each convolution occupies $\frac{1}{2}$ in., and, assuming the cores to be 7in. long, each layer will have 56 turns, and there will be seven layers.

The resistance of 500ft. of No. 10 wire, according to wire table, is $\frac{1}{2}$ ohm; and therefore the fall of potential in the field winding with 10 amperes will be 5 volts, according to Ohm's law.

We have calculated that the armature will have two circuits, each consisting of 300ft. of No. 11 wire. The resistance of one of these is 8 ohms, and of two in multiple arc, as is the case here, is 4 ohms; consequently, the fall of potential due to the resistance of the armature is 4 volts.

The counter E.M.F. has already been found to be 102.3 volts, adding to this the drop of 5 volts in field and 4 volts in armature, we have 111.3 volts as the total E.M.F. required to be supplied to the motor, which, multiplied by 10 (amperes) gives 1,113 watts as the total electrical power absorbed by it.

The net commercial efficiency of such a motor should be 75 per cent., hence the actual mechanical power developed will be equivalent to $.75 \times 1,113 = 834$ watts; and allowing 10 per cent. more as a margin we have 750 watts, or 1 h.p., almost exactly, as the true working power of this motor.

In the same way and using exactly the same data and principles, any other motor or dynamo may be designed, and its proportions and constants predetermined.

I have assumed throughout the above that the materials and construction are good. The wrought iron, copper wire, &c., should of course be of good quality. The armature core should be made up of laminæ of soft sheet iron, separated by tissue paper or other insulator, and the shaft, bearings, and other mechanical parts should be large enough and properly made. Otherwise the machine will not come out as it should.

WEYMERSCH BATTERY TESTS.

We have received the following report of Messrs. H. Alabaster, Gatehouse and Co., made to Mr. McKenzie, relating to a new primary battery, which is interesting in that the result shows a nearer result to the theoretical consumption of zinc than has hitherto been the case in primary batteries.

"In compliance with the request which you made to us towards the end of last month, that we should conduct a series of tests with, and report upon, a new depolarising liquid discovered by M. Weymersch, and employed in batteries of the Bunsen type, we beg to submit to you the results of our investigations.

"A preliminary trial was made with three square open jars, each having the following internal dimensions 8 $\frac{1}{2}$ in. by 8 $\frac{1}{2}$ in. by 12in. deep. The quantity of sulphuric acid and water, in the proportion of 1 to 20, in each jar, was about 16 pints. Immersed in this solution were two 6 $\frac{1}{2}$ in. wide zinc plates, to the depth of 6 $\frac{1}{2}$ in. Between the zinc plates, and placed in a porous pot, 7 $\frac{1}{2}$ in. by 1 $\frac{1}{2}$ in. by 12in. deep, containing nearly 3 $\frac{1}{2}$ pints of the depolarising fluid, was the carbon electrode, of the same linear dimensions as the zincs. These cells were connected in series to an ammeter, the current being adjusted by iron-wire resistances to 10 amperes, or thereabouts, and kept in circuit for 26 hours. The results obtained showed that the battery ran for 26 hours without the current ever falling below 10 amperes, or varying more than 5 per cent., and with a drop of less than 5 per cent. between the maximum and minimum free potential of the cells, whilst an actual rise in the working or available E.M.F. took place. The measured consumption of zinc in the battery, moreover, was only about 8 per cent. above that indicated by theory.

"We then decided to employ another battery of five cells, precisely similar in all respects to the above, and in the

table appended hereto all the necessary data is furnished. After keeping the cells on closed circuit for 31½ hours, we were compelled, owing to our desire not to leave the battery alone through another night, to put an end to the experiment, although we have not the least doubt that several hours more work could readily have been obtained before the electrical constants were reduced to the extent of rendering it undesirable to continue the readings. During this lengthened run it will be seen that the free potential of the battery did not vary more than approximately 3 per cent., that the working electromotive force was practically the same at the end of the test as in the beginning, and that the current varied only between 10 and 10.6 amperes. The actual and theoretical consumption of zinc differ by only 10 per cent., which agrees closely with the data obtained in the preliminary trial, the weighing of the electrodes in the last run having been carried to a greater degree of precision and exactitude, necessitating the employment of grains in balancing plates of zinc, each weighing nearly 3lb.

"The electrical measuring instruments which had very kindly been loaned to us by Messrs. Sharp and Kent, were independently checked by Mr. H. R. Kempe and Mr. W. M. Morley. The price per h.p. hour agrees more closely with the theoretical cost of batteries in which zinc is consumed than that of any other with which we are acquainted, although, of course, the precise figure will largely depend upon the charge per gallon the inventor chooses to make for the depolariser, which, we are informed, can be manufactured at sixpence per gallon.

"We have not hitherto had any battery submitted to us which has given results approaching those above tabulated, and we have no hesitation in expressing the opinion that M. Weymersch has effected a great advance in two liquid primary batteries. We may add that the liquids did not appear to rise in temperature during the whole period of the test, a fact which we imagine is unprecedented in batteries of the Bunsen type.

"It has long been the aim of inventors to discover a primary battery which should give a high electromotive force, possess a low internal resistance, and give a large and constant current for a considerable period of time with the minimum amount of attention and at the lowest possible cost. In our opinion, M. Weymersch has distanced all competitors in the attempts hitherto made to fulfil the above conditions."

GAS OR ELECTRICITY. The policeman settled the question the other day, when a leaky gas pipe exploded and blew up the footpath. Some said it was sewer gas, and some thought it was the electricity which had got buried from the late storm; but the bobby said he knew all about, "It's nothin'. Only the telegraph's busted!"

PROTECTION OF BUILDINGS FROM LIGHTNING.*

BY PROF. OLIVER J. LODGE, D.Sc., F.R.S.

Lecture I.

One hundred and fifty years ago the nature of lightning was unknown. Several persons assumed that it had some connection with the phenomena excited in a piece of glass tube when rubbing it, phenomena which were called electric; but no proof of the connection was attempted. The proof that lightning was in fact nothing but a large electric spark was given, as you know, in 1751, by that marvellously comprehensive and common sense genius, the Philadelphian printer, Benjamin Franklin.

This great man, a statesman of the first magnitude, might have made one of the first experimental philosophers, had he lived in quieter times instead of having to take a prominent part in the Declaration of Independence and in the great American War. A space of some twelve years limits his active devotion to electrical matters, but in that time he acquired a masterly grip of the subject, expressing himself very accurately and precisely concerning electrical theory, his statement of which is far superior to a great deal that has quite lately passed current in text books; indeed, it is only now becoming capable of improvement through the labour and the inspiration of some of the still greater giants of our own day.

From the time that Franklin flew his kite at Philadelphia and ascertained beyond cavil the true nature of lightning from that time to the present the protection of buildings and ships from its destructive agency has been mainly a matter of detail and application of the laws of electricity so far as they were known.

For a long time the erection of lightning conductors was opposed by the religious world as heretical and impious. But, first in some Protestant provinces in Germany, and later in France and England, the use of the heretical rods gradually extended. The extension of their use in England and their application to ships were greatly aided by the labours of that enthusiastic worker, Sir W. Snow Harris. Their extension in our South African colonies, where violent thunderstorms are frequent, is largely due to the influence of the late Dr. Mann, in whose honour this course of lectures has been established. Anyone who has read or heard Dr. Mann's contributions to the *Journal of the Society of Arts*,† must have been struck not only with his keen interest and enthusiasm, but also with his grasp of fundamental principles, his open-minded, receptive attitude to new controvertible views, and the thoroughly practical and business-like way in which he handled the subject.

Concerning the origin of atmospheric electricity, I have not much to say. It seems to me probably due to friction, like Armstrong's hydro-electric machine. Faraday showed that the exciting cause in that apparatus of Armstrong's was the friction of water spray driven by steam over the solid surface of the jet, so, also, I picture winds in the atmosphere driving the spray of mist against rock and ice surfaces, and so gradually producing a certain difference of potential between the upper layers of the atmosphere and the surface of the earth.

I have spoken as if I thought the friction had to be

* Dr. Mann Lectures, delivered March 10, before the Society of Arts, & *Journal of the Society of Arts*, April 30, 1875, and March 15,

between mist globules and solid matter. It seems doubtful whether friction against air will suffice to render water electric. If it is efficient, then it is well to notice that, though there is no finite slip between bodies and the common air through which they move, yet this does not apply to rarefied air. The viscosity of rare air is as great as that of dense, but the slip of solids through it is another matter. In rare air there is an actual slip at the surface, and accordingly the apparent viscosity of rare air, as observed by the settling of dust or the falling of a feather in a vacuum, is less than in air at common pressure. It may be, therefore, that the finite slip of mist or dust particle through the upper layers of the atmosphere is one effective cause of atmospheric electrification; and after a spell of dry weather there is liable to be an accumulation of electricity, because it has had no recent opportunity of escape.

In the polar regions electrical discharges are mainly silent, or brush-like, giving the fantastic forms of aurora; but in our latitude these silent discharges in the upper semi-conducting rarefied layers of atmosphere are seldom visible. We see the effect in another form. The electrification gets occasionally conducted down by clouds into the lower and denser layers of atmosphere. By the aggregation of small globules into great ones the potential is enormously raised, until in the lower atmosphere they flash either into each other or into the earth, and the strain is partially relieved.

It is important to note that clouds appear to play only a secondary part in the phenomena. The upper regions of atmosphere are at a different potential from the earth—cloud or no cloud. Clouds are able to conduct it down towards the earth, and thick, dense clouds are therefore the usual prelude to a thunderstorm.

The way in which coalescence of small charged globules into larger globules is competent to raise their potential enormously is well understood, and I need not dwell upon it,* but the converse operation, or the tendency to coalescence of globules produced by feeble electrical charges in their neighbourhood is not so well known, and I proceed to show the very simple experiment described by Lord Rayleigh, with a water jet and sealing-wax.

A vertical jet, about one-twentieth of an inch in diameter and three or four feet high does best, but almost any fairly vertical jet of clean water will serve. The drops fall as a scattered shower, like fine rain, until a stick of sealing wax is held a yard or two away; they then instantly collect into large globules and fall as a thunder shower.

We have now to think of ourselves as living always between the coatings of a large condenser or Leyden jar, the upper coating the sky, the under coating the earth, the common air is the dielectric between. Ordinarily the sparking distance is far too great. Every now and then portions of the upper coating protrude down as clouds, and we are then liable to a disruptive discharge. Some square miles of cloud and some square miles of land are the two coatings, and the interval of separation need not be extremely great. If the cloud and the earth were perfect conductors, all this great area would be relieved in a single flash of awful size; but, fortunately, the conduction of cloud is a slow process, and it usually takes a good many flashes from different parts to remove its charge.

The total maximum energy of a given area of cloud at a given height from the earth is easily estimated, for it is well known that as soon as the electric tension of air reaches the limit of about half a gramme weight per square centimetre, disruption occurs. Supposing it all equally on the verge of giving way, the energy of the dielectric per cubic centimetre is therefore 981 ergs, and per cubic mile is $4,110 \times 10^{11}$ foot-ton—70,000,000 foot-ton.

Given, then, the whole area of cloud facing the earth, and its height when on the point of discharging at every point, and you have the number of cubic miles of strained dielectric, and an approximation to the energy of the storm, at the rate of 70,000,000 foot-ton per cubic mile.

The potential needed to give a spark a mile long is so enormous that the quantity of electricity required to give this energy need not be very great, $2,176 \times 10^9$ electrostatic units of quantity per square mile would give a bursting tension. Now, $2,176 \times 10^9$ electrostatic units is just about 70 coulombs, or not enough to decompose one hundredth of a gramme (1/7th of a grain) of water. Faraday stated this, but it is often disbelieved.

As to the cause of the curious V shaped troughs or depressions and horizontal wheels that are often found associated with thunderstorms, I have no suggestion to offer, but on these heads I may refer to Mr. Abercromby's recent little book on the "Weather" (Int. Sci. Series, 1887).

Thinking now of a cloud and of the earth under it as forming

* See a lecture on "Thunderstorms," by Prof. Tait, in *Nature*, August, 1880.

† The difference of potential for a spark a mile long, between flat plates, is roughly 16×10^9 electrostatic units.

the two coats of a Leyden jar, in the dielectrics of which houses and people exist, we have now to consider what determines a discharge, and what happens when the discharge occurs. The maximum tension which air can stand is half a gramme weight per square centimetre. At whatever point the electric tension rises to this value smash goes the air. The breakage need not amount to a flash—it must give way along a great length to cause a flash; if the break is only local nothing more than a brush or fizz need be seen. But when a flash does occur it must be the weakest spot that gives way first—the place of maximum tension—and this is commonly on the smallest knob or surface which rears itself into the space between the dielectrics.

If there be a number of small knobs or points, the glow and brushes become so numerous that the tension is greatly relieved, and the whole of a moderate thunder cloud might be discharged in this way without the least violence. This is by far the best way of protecting anything from lightning; do not let the lightning flash occur if you can possibly avoid it. But one cannot always prevent it, even by a myriad of points. A good deal more might be done in this direction than is done, but still, sometimes a cloud will descend so quickly, or it will have such a tremendous store of energy to get rid of, that no points are sufficiently rapid for the work, and crash it all comes at once. One specially noteworthy case when points are no protection occurs when one cloud sparks into another, and thence to the ground; or, in general, whenever electric strain is thrown quite suddenly upon a layer of air. (See Lecture II. for details.)

When a flash occurs, a considerable area is relieved of strain, and the rush of electricity along the cloud and along the ground toward the line of flash sets up a state of things very encouraging to another or secondary flash or flashes practically simultaneous with the first.

One consequence of this is known as the back stroke or return stroke. It was studied by Lord Mahon, and depicted in his work, "Principles of Electricity," published in 1780. Prof. Tyndall has made it extremely well known, so that a reference to it is made in almost every elementary science school in the country.

But the popular account of the matter is, I believe, very inadequate. It says the man's electrical condition is disturbed by the inductive action of the cloud, and that, on the cloud being discharged, the man's original condition is restored, the passage of the induced charge from his hat to the ground being enough to kill him.

Now the shock that a man could get that way is but feeble, it is only twice what he would get if completely isolated and exposed to inductive action. The amount of charge stored up in a man's hat is not great; the electric tension is more likely to pull his hat off than its release is likely to do him any damage.

I do not deny the existence of this static return shock, but I assert it to be unpotently feeble. One can feel all there is to feel by holding a hat near an electric machine till nearly bursting tension, and then discharging the machine. There is no special object in waiting for a thunderstorm.

There is more in the term "return stroke" than a mere recovery from static disturbance of equilibrium. It is a matter to which I must return at some length next week.

Now proceed to the kind of damage done when a building is struck, and to the customary and orthodox modes of protecting them from the effects of a flash when it does occur, as well as if possible, of warding off the flash altogether by silent discharge. The two main destructive aspects of a lightning flash are (1) its disruptive, or expanding or exploding violence, (2) its heat.

The heating effect is more to be dreaded when the flash is slow and much resisted; the bursting effect when conducted well except at a few places. A noteworthy though obvious thing is that the energy of the discharge must be got rid of somehow. The question is, how best to distribute it. It is no use trying to hoist-potomac the energy out of existence by saying you will conduct the charge to earth quite easily and quietly.

The disruptive effect is well shown by the effect of lightning on trees. It is as if every coil were burst by the expansion in the path of the discharge. The effect on conductors is, however, just as marked. Here are five specimens of wires deflagrated on glass by a Leyden jar discharge—gold, silver, copper, iron, and platinum, each has its characteristic trace, by which it can easily be recognised.

[A number of pictures of damage done to buildings and ships by lightning were here thrown upon the screen. They are mostly contained either in Mr. Anderson's work on Lightning Conductors or in Mr. Tadmanson's on the Thunderstorm, or in both.]

St. George's, Leicester, is a curious case for the rod of the vane conducted the flash half way down the spire, when it blew a ring of stones out, and so droppled the top half of the spire neatly inside the bottom half, making a tremendous smash, carrying away all the floors of the tower, and heating in the foundation arch.

Ships may have a mast utterly destroyed and split to pieces—thick iron hoops binding the mast being rent asunder and flung about by the force of the expansion; or the heat of the flash may ignite the sails, or other combustible matter.

Now take a few examples of buildings or ships more or less protected by conductors. Some of these examples are very instructive as calling attention to the vagaries and unexpected behaviour of powerful flashes. It is these vagaries which I consider have been hitherto unexplained, and it is precisely these to which I wish to direct your special attention.

I shall hope to show next week how closely and completely they can be illustrated by laboratory experiments, and I believe that it is to a neglect and misunderstanding of these phenomena that so many of the partial failures of conductors have been due.

For that conductors often fail is undeniable. It is customary to say they are not properly made, or that there was a faulty joint, or that there was a bad earth. A bad earth is the favourite excuse. A good earth is a good thing undoubtedly, and one cannot well have too much of it, but for a flash to leave a fine thick copper conductor on a tall chimney while still high up, and begin knocking holes in the brickwork in order to make use of the soot, or the smoke, or some bolts, or other miserable conductors of that sort, because it is not satisfied with the moderate allowance of earth provided for it at the bottom, is evidence either of simple perverseness, or else of something more deep-seated not yet properly called attention to.

If the earth is bad, the flash can show its displeasure when it gets there by tossing it about, and boring holes into it, and breaking water and gas mains; but at least it might leave the top and middle of the chimney alone—it might wait till it got to the badly conducting place before doing the damage. Yet it is notorious that on high chimneys a flash often refuses to follow a thoroughly good conductor more than a quarter or half way down, but takes every opportunity of jumping out of it and doing damage. Why is this? Well, that is the main question I shall attempt to answer in this course.

It may be said that the effect of the bad earth is to make the whole path so highly resisting that the discharge necessarily declines to take it. Well, if that were so, it need not have come into the conductor at all. It is supposed with one breath to strike the conductor because it affords an easy path to earth, and with the next it is said to leave the conductor, because after all it finds it a bad one.

Besides, it need not be so very particular about a little resistance; it has already come through, say, half a mile of clear air—it might manage a few feet of dry soil. It strikes violently through the air, enters the conductor, and begins to go quietly. Why does it not continue to go quietly till it gets to the bottom of the good conductor, and then begin displaying its vigour by boring holes below, as it has done above? Why should one end have to be so persistently cocked up? Why not insist upon having not only a good "earth," but also a good "sky"?

Let me repeat, a good earth is a good thing, and it is not possible to have too much of it, except on the score of expense, but even if it were so good an earth that it might be almost called a heaven, it would not stop the tendency to side flash. One would still be liable to spittings out from conductors, especially from tall stout ones, as I shall hope to clearly show next time. However bad an earth may be, it can hardly be worse than one afforded by soot, and bricks, and yards of air.

My position at present is that an earth is desirable to prevent damage to pipes, foundations, and other things buried therein. But that, so far as getting rid of the flash is concerned, it ought to suffice if the conductor was cut off level with, or even a foot or two above, the ground. It would knock things about in jumping the rest of the way, but it should not be expected to leave the conductor until it gets to the break, any more than it should be expected to take the conductor half way down instead of at the top. It is true it sometimes does partially take the conductor at the middle, just as it sometimes partially leaves it at the middle, but I say that it is not to be expected to do either of these things on ordinarily accepted principles. There are some differences between the behaviour of positive and negative electricity, but none of such extent as will explain the extraordinary difference between the two or three points pointing skywards, and the extensive roots advocated at the other end.

Take these examples now. A house where the lightning, having struck the conductor, flashes off from it in two places to get to a roof gutter and a distant water-butt. Here is a ship where the lightning is striking in two places at once, the top of the mast and the yardarm. In the next it is striking at the top of the conductor, and also at a point on deck, and at two places on land as well. This is a most instructive example. I have little doubt that the three are echoes or reverberations of the main flash, and excited by it, not excited by induction, as in a coil, still less by mere static return, but by a surging or momentum of electricity, of which I have more to say. The next diagram shows the ship "Conway," capably protected, except as to its flagstaff. The water was seen to be luminous in conducting away this flash from the sides of the ship. Here is the arrangement by Snow Harris of conductors able to accomplish this pro-

tection—simple and effective. A ship is an easy thing to protect, provided you realise that every mast and every spar is liable to be struck. If you protect the masts, you may chance the spars if you like; but you are not to think of areas of protection; all such ideas are perfectly illusory.

(Figures of certain houses with elaborate conductors were shown.)

Nothing projecting upwards is left unspiked, and the earths are thorough. These appear to be examples of excellent, though certainly expensive protection.

If these houses were powder magazines, we should have to be more careful still and make a more critical examination, but as ordinary houses they are safe so long as the conductors are in decent condition.

Now, rapidly run over ordinary good orthodox conductors. First, the sky end. Points are good, as explained, but platinum points are liable to be melted. The best points are cones of copper, not too sharp, and thickly gilt. Gold is better than platinum in being just as durable and much better conducting, and therefore less liable to melt. Many points are better than one, especially as some are apt to get fused and blunted by some discharge; others may still remain sharp.

True, anything will act as a point when the tension rises high enough; but the great thing is to keep down these dangerous tensions as if any way possible. So soon as a knob begins to omit brushes, the sparking point cannot be far distant; but sharp points will glow and reduce the strain far before the sparking point.

Perhaps the best protected building in the world is the Hôtel de Ville at Brussels, the hobby of M. Melsens. The whole system used in this building is excellent, and theoretically perfect, so far as I know, in every respect; but it is not cheap, and some people might perhaps hold that it was not artistic.

As for the main conductors, one finds rod, rope, and ribbon. The plan most approved, perhaps, by the lightning rod conference is this copper tape, which is very nice, neat, and flexible, and free from joints.

Two important matters to be thought of in connection with the conductor are—that it shall not corrode away in places, and shall not be stolen. Another point that must not be overlooked in fixing up any length of conductor is that it is liable to expand and contract. An allowance must be left for this. When it is remembered that it is liable to be exposed to the full glare of the sun, backed up sometimes by a kitchen chimney behind, and then again at another time exposed to the coldest nights, a range of 100 deg. C. is not excessive.

I once rigged up some copper rod battery conductors of substantial thickness between two walls, and one morning after a frost found one snapped clean in half by the contraction. This would be a bad thing to happen to a lightning conductor, so either bends must be left in the rope when put up, or else special compensators must be introduced at intervals.

The allowance for copper is one in 500, say an inch in every 40 ft. The best place for a compensator is just above a holdfast, so that it will have to support no weight. A bight or bend in a flexible rope answers every purpose, but bends should not be made too sharp, or the discharge will jump across instead of going round. That is a thing to be remembered. Flexible conductors are very convenient, but their convenience must not be abused. Always take them as straight as possible. Lightning has no time to go round circles—it will jump across sooner. Why should it not be let to jump across? Well, because it burns the conductor. That is the real objection to bad joints—the extra heat; a sort of arc produced there, and the liability to fusing and destruction of the conductor at these parts. There is, moreover, some danger from fire.

Now about the earth end. We have had examples of good earths already. Here is a cheap one advocated by Dr. Mann: wire rope opened out into a brush, and the two ends of another short bit, similarly treated, spliced across the first. Two of the fuzzed out ends make contact with deep soil, one with the surface soil, so that one or other is pretty sure to reach moisture.

The whole conductor introduced into the Cape by Dr. Mann is simple, cheap, and admirable for cottage purposes and for emigrants. Squatters in the States, or Canada, or at the Cape are far more liable to thunderstorms than we are in this country, and they should certainly rig up one of these homely things. A lot of iron fencing rope will do, with both ends fuzzed out, one supported by a tube fixed to the chimney, the other sunk deep into moist ground, or swamp if available.

In towns where there are water or gas mains anywhere near the terminus of a lightning conductor, they should always be connected to it, and this mainly for their own protection. For if they be not connected, the lightning will not scruple to still make use of them if he chooses, and having to jump across a yard or two of bad conductor on the way, it can easily knock a hole in them or melt them, instead of getting to them quietly.

It must be understood that what I say of the mains and underground does not apply to the pipes in a house. To connect lead water-pipes with a lightning-conductor might possibly lead to their being melted; but to connect the house gas pipe with

* For an example of the entire failure of a brass rod, 1 in. in diameter, see Anderson's book, p. 137. For cases of capricious leaving of a conductor for such things as safes and fowling-pieces, see pp. 250 and 273.

a conductor is a most dangerous proceeding. The neighbourhood of gas pipes in a house must scrupulously be avoided. The more it is connected to the mains underground the better, but one does not want lightning rushing along soap-pipes, picking out all the bad joints, and lighting all the gas there. In so far as a house contains escaping gas or weak gas pipes, it must be treated like a powder magazine, and great care be taken. A ridiculously minute spark may ignite gas without being noticed, the hole in the pipe may quietly enlarge, and the house be burnt down. A considerable amount of damage has been done in this way. So soon as Swan lamps are in universal use, lightning may occasionally play havoc with their filaments and fuse a few cut-outs, but it will not find the leads easily combustible or capable of burning the house down.

Whether it be gas or electric light, however, lightning should, if possible, be kept out of the house leads not only because of the danger it may do at joints and insulation, but because the gas brackets and chandeliers are usually conveniently suspended over desks and near arm-chairs, just where an unsuspecting person's head is likely to be, and a spark to one's head is unsafe.

Hitherto I have spoken of the orthodox system of protection, the gather up and carry away system. But, as you know, there is another system suggested by Clerk Maxwell, the birdcage or meat safe principle. In a banker's strong room you are absolutely safe. Even if it were struck, nothing could get at you. In a birdcage, or in armour, you are moderately safe. I should not care to try armour myself, the joints might get unpleasantly hot and explosive. And even the birdcage, if struck by a big enough flash, might get melted. A melted patch on one's protective armour would be extremely disagreeable. Sometimes one is told to get thoroughly wet through instead of seeking shelter in a thunderstorm; but it is a question whether a stroke is more unpleasant than rheumatic fever.

However, a sufficiently stout and closely-meshed cage or netting all over a house will undoubtedly make all inside perfectly safe. Only, if that is all the defence, you must not step outside, or touch the netting while outside, for fear of a shock. It would be unpleasant, when you reached home out of a storm, to find it so highly charged as to knock you down directly you tried to go in. An earth connection is necessary as well.

A wire netting all over the house; a good earth connection to it at several points, and a plentiful supply of that barbed wire which serves so abominably well for fences, stuck all over the roof, and you have an admirable system of defence.

Now let us see how far most people agree, and where they begin to branch out and differ. The old and amusing political controversy between knobs and points has disappeared. Points to the sky are recognised as correct, only I wish to advocate more of them, any number of them, rows of them, like barbed wire not necessarily at all prominent—along ridges and eaves. For a point has not a very great discharging capacity. It takes several points to discharge readily all the electricity set in motion by a moderately-sized Voss or Wimshurst machine. Hence, if you want to neutralise a thundercloud, three points are not so effective as 3,000.

No need, however, for great spikes and ugly tridents, so painful to the architect. Let the lightning come to you; do not go to meet it. Protect all your ridges and pinnacles, not only the highest, and you will be far safer than if you built yourself a factory chimney to support your conductor upon. At present the immediate neighbourhood of a factory chimney or steeple is not a safeguard, but a source of mild danger. But no one need believe this till after next Saturday, and not then if the experiments fail.

Next, as to the conductor. Should it be iron or should it be copper? Should it be insulated from the building, or should it be connected with all the metal it contains? These are questions at present in dispute. The lightning rod conference approves copper, though not putting it specially and strongly before iron. Durability is its main recommendation. Under all circumstances I am not sure whether it is more durable than galvanised iron. Mr. Preece has great experience of wires in chemical and all other districts, and I believe he upholds iron. Franklin and the Americans to this day prefer iron. Certainly it is much cheaper, and not so easy to melt. We will consider the question, and, I think, come to a definite conclusion next week.

Also the question about connecting up the conductors to all metal masses, roofs, girders, balconies, water gutters, &c., we had better leave that open too. Nearly everyone condemns insulators, but one eminent authority, M. Callaud, advocates caution and circumspection in what things you connect and what you do not connect. He points out, for instance, that if you connect up a balcony to a conductor, a person standing thereon may become one of its striking terminals. I must say I agree with him. Some there are who advocate connecting both ends of a roof gutter, or other such nearly-closed contour, and not only one end. I decidedly agree with this also, for reasons which next week will make abundantly clear. On this point I have, in fact, no doubt.

As regards the shape of the conductor, whether rod or ribbon? Many experiments have been made, notably some by Mr. Preece on the discharge of Dr. De la Rue's battery through conductors of various sectional shapes, to see if extent of periphery matters. Hitherto the results have been negative. We may conclude, I think, that it does not matter much as regards liability to be deluged. But theory clearly points to the fact that a bundle of detached wires is electrically better than a solid rod of the same weight per foot, in every respect except durability. But durability is an essential feature. No shape can be considered satisfactory which aids corrosion. One thing is obvious—plenty of surface encourages cooling, and slightly diminishes danger of melting. Its other much more important advantages we will consider later.

Lastly, the "earth" and its testing. An earth is necessary, or you will have your foundations knocked about and your garden ploughed up. A good earth is desirable. A few tons of coke with the conductor coiled up amongst it is a well-known and satisfactory plan if the soil be permanently damp. A bag of salt might perhaps be buried with it to keep it damp throughout, or rain water may be led there. Often, however, the most violent thunderstorms occur after a spell of fine weather, and the soil is likely to be dry. It is best, therefore, to run your conductor pretty deep, and there make earth.

It is all very well to connect the conductors to water mains if near, but if they are far off or non-existent it is no use, and in no case, in my opinion, should they be used as sole earths. Certainly not gas mains. In dry weather they are not earthed at all well, and a strong charge may then surge up and down them and light somebody else's gas in the most surprising way. It does not often happen, but it may happen in sandy soil after dry weather. Always there should be a good deep earth, a well if possible, a boring if not—and the conductor be led down into it. If it likes to make a disturbance when it has to leave the conductor a long way down, no one need grumble. It can't do much harm there. There is, of course, no magic in water, unless it forms a large continuous sheet. An isolated puddle in a rock, such as has been used hitherto now for a lighthouse, is no earth at all. A thoroughly good earth is really a geological question; and for an important building a geological specialist should be consulted.

An occasional test of an earth, in ordinary weather, is no real security as to what may happen after a long-continued drought. It would be easy to arrange a plan whereby just raising a handle shall give sufficient information as to the state of the earth, without any skilled operator. To this end, two earths should be provided, quite independent of each other (one a water-main, for instance, the other a ton of coke), and they should be connected, first to each other and then to the conductor, by a substantial copper band. Now let the band connecting the two earths pass through some covered outhouse, and have a well overlapping junction of two flat areas pressed together by a spring, but capable of being raised on or off the other by pulling at a handle or a rope. A galvanometer indicator and Leclanché cell, permanently connected so as to send a current between the two earths directly the handle is raised, will show by its deflection the state of conductivity of the two earths. Very likely the two earths themselves will suffice to give the necessary current without an auxiliary battery.

There is this to be said, however. If a building is so situated, either on high sandy ground, or on impervious rock, that a decent earth is very difficult to get, then, at least, the house is not likely to make a better earth than the conductor. That is a weak point in the excuse so often made concerning an accident to a protected building, that the earth was not sufficiently good. It can very seldom be shown that the earth, apparently chosen in preference, was any better. Often it was obviously worse.

It is a superfluous to place much reliance on the testing of conductors with a galvanometer and Wheatstone bridge. A galvanometer and Wheatstone bridge are powerless to answer many important questions. A Leclanché cell can no more point out what path lightning will take, than a trickle down a hill-side will fix you the path of an avalanche. The one is turned aside by every trivial obstacle, and really chooses the line of least resistance; the other crashes through all obstacles, and practically makes its own path. A flash strikes a house at one corner, rushes apparently part way down the conductor, then dashes off sideways to a roof gutter, sends forks down all the spouts, and knocks a lot of bricks out. Another branch bangs through a wall in order to run aimlessly along some bell wire, and then out through a window-frame, and down a spade or something propped up against the wall to earth. The lightning tester comes with his galvanometer and Leclanché cell, and reports that the earth of the conductor has 100 ohms resistance; and the accident is therefore accounted for. But how much resistance would he have found in the paths which the lightning seemed to choose in preference to the 100 ohms? Something more like 1,000,000, probably. Or perhaps there is a bad joint in the conductor somewhere, the parts being separated by one-sixteenth of an inch. But why should it prefer to jump several yards, and knock holes in walls and windows, rather than jump one-sixteenth of an inch? No; the galvanometer, and

Wheatstone's bridge, and Ohm's law, and conductivity, are simply not in it.

Something has been left out of consideration, and something very important, too; and until that something is fully taken into account no satisfactory and really undomable security can be guaranteed.

That something is inertia—electrical inertia. Suppose you have a pipe or U tube full of water, used as perpetual overflow to a cistern, and you want it to be equal to all demands. You test it, and find it perfectly easy to pour the water either way, both ends are perfectly open; the pipe is a good conductor. Then comes someone and hits the stagnant water in your pipe a tremendous blow with a hammer, bursts the pipe, and scatters the water all about. That is what lightning does to your lightning conductor and to the electricity in it. It is no gentle push, it is a terrific blow.

Conductivity is not what you want, widening the pipe is no remedy. There is a something you want, there is a remedy.

The remedy is elasticity—electric "capacity." You must reduce the electrical inertia (or self induction) of your conductor as much as possible, and you must increase its electric elasticity (or capacity) wherever convenient. These are matters concerning which I have many experiments to show next week.

BRADFORD ELECTRIC LIGHTING.

The following is practically the full text of the discussion in this matter at the meeting of the Council last week.

A communication which had been received from the Local Government Board with regard to the electric lighting scheme for Bradford was read by the Town Clerk. The communication was to the effect that the authorities had had under consideration the council's application for borrowing powers for the purposes of the scheme, and now sent down an authorisation for the council to borrow £20,000.

Alderman F. Priestman, chairman of the Gas Supply Committee, moved the adoption of the minutes of that committee, which, amongst resolutions accepting the tender of Messrs. J. and W. Beaman for excavating, brickwork, ironfender and smith's work, masonry, carpentering, joinery, plumbing, glazing, &c., in connection with the electric lighting works, for £3,690, the tender of Messrs. Helliworth and Sons for the supply and fixing of three milsted boilers and fittings for £2,125, and the tender of Messrs. Siemens Brothers and Co., Limited, for the supply and fixing of dynamos and all the appliances for £12,543, the total cost of the proposed installation being £18,358. Further, the committee recommended that the council should authorise the Gas Supply Committee to apply to the Local Government Board for authority to increase the sum to be borrowed for electricity works to an amount not exceeding in the whole £25,000. **Alderman Priestman** said he did not think it necessary to go at any great length into the details of the proposed scheme, inasmuch as it was practically the same scheme as that which had been brought before the council in December last, when they had passed a resolution authorising the Gas Supply Committee to spend not more than £15,000 upon the scheme. That resolution was confirmed on February 14th, when the council instructed the Town Clerk to apply to the Local Government Board for leave to borrow £20,000 to carry out the scheme. In moving the resolution in December last he had promised the council that no money should be spent unless the council had first had the fullest information which it was in the power of the committee to give, and, therefore, it seemed to him to be due to both the council and the committee that he should now describe step by step every course which the committee had taken, in order that they might ensure that whatever money was spent had been expended well and without waste. Immediately after the passing of the resolution in December the Gas Supply Committee determined that, in addition to having the report from Mr. Shoolbred, they would consult the eminent electrician, Dr. Hopkinson, who was called upon to come to Bradford and see Mr. Shoolbred's report. Dr. Hopkinson came to Bradford and had several hours' consultation with the committee, and went over the ground, in order that they might, when they had finished the consultation, feel quite sure that they were taking a right step. There was a general concurrence between the opinions of the two specialists, and upon points upon which they differed each gave way slightly. The only difference of real importance was as to whether the two-wire or three-wire system should be adopted, but in the end it was arranged that first of all the former should be put down, as it was acknowledged to be simpler than the latter, and so that if the installation were afterwards extended the three-wire system could be easily adopted. Not satisfied merely with the report of Dr. Hopkinson, the committee decided to see for themselves a number of instalments in different parts of the country. They saw the instalments, and then came to the conclusion that in following the advice upon which they were acting, they had taken the wisest course which they could have done. Mr. Shoolbred was invited to prepare detailed specifications of his proposed scheme and then tenders were invited. A public inquiry was subsequently held by an inspector of the Local Government Board, and, as proving the interest which the public took in the matter, he the speaker might state that, with the exception of two members of the committee and three reporters, only one person was present who was not directly engaged in the inquiry. The tenders had been determined upon. Messrs. Siemens and Co., Limited, were providing the whole of the electric appliances, including the dynamos and fittings, and were to superintend and manage the works for a period of six or eight weeks after the latter were completed. The total amount of the tenders came to £18,358. To that

they must add £2,000 for contingencies, and that brought the total up to over £20,000. The small balance of £5,000 would be required for the carrying on of that important work. The reason why they were asking for more money was that the installation was to cover a somewhat larger area than that which had been proposed in the first instance, and, further, because the works were to be of a permanent, and not of an experimental character. The committee had felt as they had gone along that what they doing would be of a permanent nature, and that they would rather have to extend their installation than give it up. Everything had been done with a view to the future, and so that if in the course of time, it was found necessary to double the installation, it would be done at a very much smaller cost than the present work. Another circumstance which had operated against the committee was that since the installation had been determined upon a large syndicate which had been formed in Paris had driven the price of copper up to nearly double what it then was, and the difference in the cost of the necessary copper would amount to £1,000 or £1,500. The committee had felt convinced that to put down an installation of less than 3,000 incandescent lamps of 16 candle power each would not give a fair test or proof of the success of the undertaking, and it was that reason which had induced them to bring before the council that resolution. He hoped that the council would pass the resolution with practical unanimity, and thus strengthen the hands of the committee, who had had the work thrown upon them because public opinion seemed to be tending in the direction of having a supply of electric light from somebody or other. If the Corporation had not gone on with these works, he believed that there were others quite prepared to do so, and that he would regard as a misfortune. He had every reason to hope and believe that the installation would prove to be an entire success.

Mr. David Barker seconded the resolution. He was not, he said, prepared to say that the success of the scheme was certain, but it was evident that the Corporation must do it, or someone else would, and he thought it was proper that they the Corporation should do it.

Mr. Galloway spoke against the resolution. He said that when the scheme was first mooted the cost was to be from £10,000 to £12,000. From these sums the amount rose to £15,000, and now the chairman of the Gas Supply Committee asked for £20,000. His opinion was that the chairman had such large ideas about this thing and that he could not be content with a small scheme. If the matter went on at this rate they would soon be asked for £25,000 or £30,000. He would like to tell both the chairman of the committee and Mr. Shoolbred that they were starting upon something that they knew very little about, and he believed that these gentlemen would be somewhat surprised before the work was finished. They had, he believed, a provisional order for Bradford—a thing which he did not believe any other Corporation in England had got. Whenever the question of electric lighting had come up their respected town clerk had something to say about it. They must not have any other bodies interfering with them—one king in a town was quite sufficient but he thought he was right in saying that the town clerk had been very badly troubled to think that the scheme might be dropped. There were large towns like Leeds, Hull, Sheffield, Huddersfield, and Halifax without provisional orders, and did they find any company trying to go into these towns with the electric light? No. And what did this mean? It meant that there was no profit at the back of electric lighting schemes. There was nothing but loss. He had heard one member of the council say that it would not much matter if they lost money by the electric lighting scheme, because £1,000 a year could easily be taken from the gas profits. The gentleman who said this wanted looking after. If they were going to swallow up the only Corporation business that paid, then it was time somebody looked into the matter. It had been stated that it would cost £50 to light a five-roomed house. If this were so, then he thought that not many dwelling houses would use electric light; he thought it would only be used for outside illumination in order to attract attention. He would like the matter to be referred back to the committee for consideration, but if the chairman was determined to go on with it, then he ought not to exceed the £20,000.

The Mayor: May I ask if Mr. Galloway wishes to move a resolution to that effect?

Mr. Galloway: I don't think I could get a seconder (laughter).

Mr. T. Pricestley expressed his belief, as the result of personal experience, that if people once got electric light into their houses they would not voluntarily return to gas.

Mr. Lobley thought that the Gas Supply Committee were entitled to the thanks not only of the council, but of every right thinking person in Bradford.

Alderman F. Priestman, in reply to questions, said he hoped the installation would be quite complete by next Christmas. Continuing, he said that circulars were now ready to be sent out to every tradesman and resident upon the line of route of the proposed installation. The circulars offered to supply the electric light, and from questions which had been asked of him he apprehended that they would have a very large number of consumers. He felt that the scheme would be successful if applied only to the Corporation public buildings, without having regard to supplying private consumers. Even if they did not spend money on electric lighting, they would soon have to spend it on additional gas supply for the time would come when the present gas works would have to be extended to meet the increased demands which would be made upon them.

The minutes were then adopted, with two dissentient votes.

Eastern Extension Telegraph Company.—The Directors of the Eastern Extension, Australasia and China Telegraph Company, Limited, have declared an interim dividend to the quarter ended March 31 last of 2s. 6d. per share free of income tax, payable on July 14 prox.

COMPANIES' MEETINGS.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.

The seventh annual ordinary meeting of this Company was held on Friday June 8, Mr. C. L. W. Fitzgerald presiding.
Mr. C. Cartoys, the secretary, read the notice convening the meeting.

The Chairman moved the adoption of the report, which showed a balance in favour of profit, including that brought forward, of £12,434. It was proposed to withdraw a total sum of £2,541, and to pay a further dividend of £2 17s making, with the interim dividend, a dividend for the year of £8 7s. The Chairman referred to several reports of interest to the shareholders, and said he looked for an increase of telephone business from the proposed fusion of all the companies in the country.

The report was adopted, and the dividend declared.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.

The third annual meeting of this Company was held on the 7th inst.

The Chairman, in moving the adoption of the report, having drawn attention to the increased business of the Company, pointed out that there was an increase of no less than 84 per cent., and a large proportion of this wire extension was on trunk lines, chiefly in South Wales, where there was a very important territory, which it was desirable they should occupy as soon as possible. The cost of trunk lines had been nearly £19,000, and the rentals were at first very small, so that this outlay had been nearly unremunerative, and at the same time there had been interest to pay. But already the trunk income was coming in rapidly and amounted to about £1,300. The total trunk calls now amounted to very nearly 10,000 a month. In September, when the trunk system was first set going, the calls were something over 5,000, and now they were nearly 10,000. Their longest line at present was that from Bath to Llanelli, a distance of about 142 miles, and, generally speaking, the messages were satisfactorily heard. The balance would have admitted of a small dividend, but the Directors, although confident of the future, advised carrying the balance to next year, making up the reserve fund to a round sum of £1,000. The general business grew rapidly, and very few weeks passed without some special suggestion. They would notice a desire had been expressed to connect London and Birmingham with the trunk wires and the system generally. Their experience showed there was a very great indirect advantage from trunk wires, not merely from subscribers and trunk calls, but by adding very materially to the exchange subscribers in the various towns. During the year trunk and reuters' wires had increased to the number of 977 miles. One interesting extension they were looking forward to, and that was a proposal to connect Edgystone Lighthouse with Plymouth. This was not only desired by the Admiralty as giving an opportunity of connecting the dockyards with the lighthouse, but it would be of great use to the mercantile marine as a signal station to the ships passing. If they could see their way to a fair return on the outlay he thought this extension might very soon be carried out. He would mention that there was a desire that the coastguard stations, and possibly some of the lifeboat stations, should be connected. At present they could not see where the income would be derived in order to meet the large expenditure which would be incurred, but if a connection was necessary the telephone was by far the best medium which could be utilized.

It was resolved that a dividend of 6 per cent. be paid to preference shareholders, and the retiring Directors were re-elected.

PROVISIONAL PATENTS, 1888.

SEPTEMBER 14, 1887.

12,437A. **Electrical measuring instruments.** Rookes Evelyn Bell Crompton and James Swinburn, Art. Works, Chelmsford. Note.—This application having been originally included in No. 12,437, dated 14th September, 1887, takes, under Patents Rule 23, that date.

JUNE 8, 1888.

8401. **Improvements in electric batteries.** Edward William Clifton and Valentine Robinson, 47, Lincoln's-inn-fields, London.

JUNE 9.

8457. **Improvements in telephones.** Emanuel Mellett, 55 and 56, Chancery lane, London. (Complete specification.)

8496. **Improvement in electro coating metals with zinc.** John Lea and Henry Ross Hammond, 166, Fleet street, London.

8503. **Improvements in magneto-electric fuses or exploders.** Eugene Ducrest, 45, Southampton buildings, London.

JUNE 11.

8525. **Improvements in electric trembling bells.** Frederick Lawrence Rawson and Philip John, 11, Queen Victoria-street, E.C.

JUNE 12.

8596. **Improvements in automatic telegraphy.** James Yate Johnson, 47, Lincoln's-inn-fields, Middlesex. (Edward Jones Mallett, United States.) (Complete specification.)

8611. **An improved form of galvanic belt for medical purposes.** William Loughton, 188, Camden-road, St. Pancras, N.W.

JUNE 13

8657. **Improvements in dynamo-electric machines.** Henry Barcroft, 64, Waring street, Belfast.

JUNE 13

8673. **An improved reflecting telescope.** William Smith and Robert Gordon Nisid, Aberdeen.

8697. **An improvement in mariners' compasses.** James Sandeman, 53, Chancery-lane, London.

8700. **Improvements in and relating to electric batteries.** Lewis Marie Joseph, Charles Clement Renard, 45, Southampton-buildings, London.

JUNE 14.

8724. **An improved appliance or switch for electrical machines or apparatus.** William Shelgrove, 77, Colmore-row, Birmingham.

8746. **Improvements in plating metals with aluminium and producing alloys thereof.** Leon Quentin Brin, 53, Chancery-lane, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

JUNE 18, 1887.

8795. **Improvements in galvanometers with suspended coils.** William Edward Ayton, City and Guilds of London Central Institution, Exhibition-road, London, and John Perry, City and Guilds of London Technical College, Finsbury.

JULY 21, 1887.

10,233. **A novel combined electrical vapor bath.** Muriel Matland, Gray's inn chambers, 20, High Holborn, London, W.C.

JULY 26, 1887.

10,381. **Apparatus or means for preventing more than one electric shock being given after the insertion of a coin into automatic or other machines in which electricity is employed.** William John Woodard, 45, Southampton buildings, London, W.C.

AUGUST 11, 1887.

11,004. **Improvements in apparatus for the electrical propulsion of tramcars and other vehicles.** Michael Holroyd Smith, 28, Southampton buildings, Chancery lane, London, W.C.

NOVEMBER 30, 1887.

10,473. **An electrical signalling device for railway purposes.** Samuel Sidney Boudie, 97, Newgate street, London, E.C. (Samuel T. Street, United States.)

FEBRUARY 9, 1888.

1932. **Improved forms of electrical contacts for switches and similar fittings.** Frederick Henry Royce, Blake street, Hulme, Manchester.

MARCH 27, 1888.

4673. **Improvements in dynamo electric machines, and in regulating and measuring apparatus for use with same.** Philip Middleton Jones, 55 and 56, Chancery-lane, Middlesex. (Charles Heiser, United States.)

APRIL 3, 1888.

4964. **Improvements in apparatus for transferring electric currents.** Alfred Julius Beut, 323, High Holborn, Middlesex. (Stefan Doubrawa, Austria.)

SPECIFICATIONS PUBLISHED.

1887.

5809. **Electric bell indicators.** J. and K. Eschby. 8d.

6918. **Telegraphy.** W. E. Gedge. (Claude.) 1s. 3d.

7042. **Electric arc lamps.** F. G. Chapman and others. 8d.

9829. **Dynamo-electric machines.** T. Stanley. 8d.

9904. **Insulating coatings for electrolytic apparatus.** L. Grabau. 8d.

10,195. **Dynamo-electric machines.** J. P. Hall. 11d.

10,575. **Instruments for electric measurement.** W. Emmott and J. H. Riler. 6d.

15,717. **Electrical date and time stamp.** C. A. Randall. 1s. 1d.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the week ending June 15 amounted to £4,760.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company for the half month ended June 15 were £2,931, against £2,792 for the corresponding period of 1887.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ending June 15, after deducting the fifth of the gross receipts payable to the London Atlantic Telegraph Company, Limited, were £3,923.

NEW COMPANIES REGISTERED.

Luther Hanson and Co., Limited.—Registered by R. Jordan, 120, Chancery-lane, London, W.C. Capital £7,500, divided into 1,500 shares of £5 each. Object, the acquisition of the patent rights in connection with improvements in electric arc lamps, field magnets, and in dynamo electric machines or motors, now the property of Luther Hanson and Charles, of North Bridge Electrical Works, New Bank, Halifax; the working of the said patent rights, and the making, exercising, and manufacturing for sale of the articles produced thereby, and the carrying on the business of electrical engineers and contractors, the supplying of electric light to towns, public and private companies, clubs or associations, mills, shops, warehouses, dwelling houses, or other premises. The first subscribers are:

	Shares.
J. Loughbottom, Woodbottom Dye Works, Luddenden Foot	20
L. Ingham, Farrer Mill, Salterhebble	20
G. Charnock, contractor, Halifax	20
L. H. Anson, electrical engineer, Halifax	100
C. Dobson, clerk, Halifax	3
J. Farrar, solicitor, Halifax	1
J. Duff, accountant, Barrow Top, Halifax	1

The first Directors shall be J. Loughbottom, L. Ingham, G. Charnock, and Luther Hanson. The qualification of the Managing Director shall be at least 100 shares; other than the Managing Director, no Director shall receive any remuneration for his services.

Automatic Electrical Corporation, Limited.—Registered by Messrs. Ashurst, Morris, Crisp, and Co., 6, Old Jewry, E.C., with a capital of £75,000, divided into 3,750 shares of £20 each. Object, to act as undertakers for the supply of electricity for lighting and other purposes within the United Kingdom and elsewhere. The first subscribers are:

	Shares.
E. J. Hernandez, 7, Liverpool-street, W.C.	1
T. G. Kneeksester, 27, Phillimore-place, Kensington	1
J. T. Blanchard, 25, Huntley-street, W.C.	1
W. D. Herby, 6, Great Newport-street, W.C.	1
E. Tritton, 8, Cannon-place, W.	1
R. G. Upton, The Canons, Mitcham	1
W. Sherratt, 401, Oxford-street	1

The first Directors shall be nominated in writing by the majority of the subscribers to the memorandum of association. The number of Directors shall never be less than three nor more than ten. The qualification of a Director shall be the holding of shares of the nominal value of £250, in respect of which all calls for the time being due shall have been paid; but in case a person not holding such qualification is

appointed a first Director his appointment shall be void, but he shall, within one month from the date of appointment, acquire his qualification. The remuneration of Directors shall from time to time be fixed in general meeting.

The Petroleum Engine Company of America, Limited.—Registered by Mullisons, solicitors, 20, King's Arms yard, London, E.C. Capital, £150,000, divided into 30,000 shares of £5 each. Object, to acquire certain American United States patents for inventions in relation to petroleum engines, and with a view thereto, to ratify and adopt the agreement between John Joseph Kereley Humes of the one part, and Ernest Whitehead on behalf of the Company of the other part, and to carry the same into effect with or without modification; to carry on either in the United States of America, and elsewhere, as may be found expedient, the business of mechanical and chemical engineers, manufacturers of engines, and workers and dealers in electricity, motive power and light, and any business in which the application of electricity or any other power or may be useful, convenient, or ornamental, or any other business of a like nature, and in the United States of America or elsewhere to manufacture and produce and trade and deal in electrical generators and accumulators, electro-motive oil, gas, water, steam or other engines, and all or any kind of electrical and other apparatus and appliances, whether used or which hereafter may be used in connection with motive powers or illumination, and whether in connection with any invention now known or hereafter to be discovered. The first subscribers are:

	Shares.
T. T. Curtis, cashier, 17, Triangle, Ruby street, Old Kent road, S.E.	1
G. T. Adams, clerk, 152, Fairbridge-road, Upper Holloway, N.	1
H. T. Adams, clerk, 106, Boyham street, Camden Town, N.W.	1
W. Micklethwait, 34, Millman street, Balford row, W.C.	1
C. Chiscol, schoolmaster, 39, Frederick street, Caledonian road	1
G. F. Tucker, stationer, 38, Kerrett road, Brixton	1
E. Whitehead, engineer's clerk, 73, Queen Victoria-street, E.C.	1

The number of Directors shall not be less than three nor more than nine. The first Directors shall be Sir Grace the Duke of Manchester, K. P., Sir Henry Cartwright, Knt., Major Alexander Ross, M. P., William Tipping, Esq.; Major General W. O. Swanton, Robert O. Ritchie, Esq., and Joshua Priestman, Esq. Each Director shall be a shareholder in the Company, and must hold at least 40 shares in the capital of it. The remuneration of the Directors shall be £200 per annum for each Director, and £100 per annum extra for the Chairman of the Board, and such further sums (if any) as shall be voted by the Company in general meeting.

NOTES.

Kensington. Kensington Parish Church was lighted last week by the incandescent electric light.

Dr. Mann Lectures.—Prof. Oliver Lodge's "Mann" lectures on the "Protection of Buildings from Lightning," which we are reproducing, will shortly be published in book form, with additional matter, by Messrs. Whittaker and Co.

Marseilles.—The Marseilles Gas Company run arc lamps as well as gas. The lamp posts are triple, with an arc lamp above, and two gas jets below. The arcs run till midnight, and afterwards the gas comes in for its share of the lighting.

Belfast. The premises of the well-known firm of Messrs. Robinson and Cleaver, linen manufacturers, Belfast, have been lighted with the incandescent electric light by Messrs. Greenhill. The light created a good deal of enthusiasm in the district.

Communication with Lightships. Several of the largest New York shipping merchants, says the *Electrical World*, are promoting a plan to establish telegraphic communication between shore and the lightships along the coast. It is hoped to carry out the scheme by the summer of 1890.

Milan.—Milan has 130 arc lamps running. Seventy more are to be added shortly. These new lamps, like those previously ordered, are on the Thomson-Houston system. The dividend declared by the Company has been 4 per cent., as against 1·6 per cent. before the Thomson-Houston system was adopted.

Turin.—Messrs. Bellani Fratelli have secured, under a fairly reasonable royalty to Government, the concession for central station lighting in Turin for a period of twenty-seven years, and have about 100 Thomson-Houston arcs running. This firm have also the sole right in Italy for use of the Thomson-Houston system.

City Guilds' Calendar. The new programme and calendar of the City and Guilds of London Institute for 1888-9 has been issued. It contains the regulations for the technological examinations for 1889, syllabus of subjects, and recommendations of books of references. It also contains the papers set at the examinations of the present year.

Alternate Current Motors. With reference to the recent discoveries by Dr. Ferrari and Nikola Tesla in the direction of alternate current motors, the question of prior invention is cropping up already. We learn on good authority that Prof. Elihu Thomson has had an alternate current motor running in his laboratory for the last twelve months or so.

Silica in Accumulators.—M. Hignette, an engineer in Paris, proposes to separate the different electrodes of an accumulator by a plate of pure silica. This disposition, he states, would have the advantage of rendering contact between the electrode impossible, without increasing the resistance, owing to the great porosity of the silica employed. Silica is a material of which we do not as yet fully know the properties, and it may be worth while for it to receive the further attention of the electrical chemists.

New Incandescent Lamps. Recent announcements that have appeared showing that the proprietors of the

Sawyer Man system, and also the owners of the Seel patents, contemplate establishing works in England, looks very much like having keen competition amongst suppliers of incandescent lamps. We learn that both Mr. H. C. Davis, president of the Sawyer-Man Electric Company, and Mr. Zacharias, representative of the Seel system, are at present in England carrying out negotiations on behalf of their respective systems.

No Zinc Used.—With reference to what it calls the ridiculous pretensions of D'Humy, a French contemporary gives the following anecdote. At a certain exhibition an inventor of a primary battery assured the unsuspecting public present that his particular battery consumed very little fluid, and *no zinc*. Some specialists, happening to be present, naturally enquired, "What do you have the zinc at all for, then?" "Just to show that none of it is used, I suppose!" said another bystander, while the inventor was casting about for his reply.

St. Bernard.—An interesting and useful application of modern science to the remains of mediæval institutions, is that of a telephone which has just been fitted between the Hospice on the Great St. Bernard, and the station in the valley below. The monks are informed when travellers are ascending the pass, and if they do not arrive at the right time, the monks can go to meet them. It has already proved of considerable assistance, six lives having been saved recently, the last two rescued being travellers who were lost in the snow fully two miles away from the Hospice.

Medical Electricity.—Our readers must be careful to note that the *so-disant* British Association (?) of Medical Electricians, which Mr. C. B. Harness, of quack belt fame, has formed principally from the staff of his own show-room for commercial purposes, has no connection whatever with the Institute of Medical Electricity, formed under the guidance of Mr. H. Newman Laurence, A.S.T.E., which is distinctly established for the purpose of opposing such misleading and unscientific enterprises, and of gathering information and providing facility for the real knowledge of electricity, as it can be applied in medical science.

A Revolution in Steam Production.—Mr. Fletcher, Chief Inspector of Alkali Works, in his annual report, just issued, deals with a number of subjects of great interest to manufacturers. His remarks upon Mr. Hargreaves' hot air engine, or thermo-motor, are specially important. He says that it will not only effect the prevention of black smoke, but promises to revolutionise our methods of producing power. An energy of 40 h.p. can be maintained with the expenditure of two gallons of coal tar or 45lb. of coal per hour. Either liquid fuel or coal can be used. This is a result three times more favourable than that realised by the best, and five or six times more than by ordinary steam-engines.

Burying Magnetised Watches.—Dr. W. H. Palford, of Ansonia, Conn., had a valuable watch apparently spoiled through getting magnetised by a dynamo. He tried to devise some way of remedying the difficulty without going to a heavy expense, and hit upon this plan. He enclosed his watch in a cloth bag, and buried it in a large box of damp earth, where it remained for three days. He then dug it up, and found that the watch was completely cured. The simplicity of the process commends itself to owners of magnetised watches, who may be thus able to effect a cure without recourse to jewellers. Their only care must be to

recollect where they bury them, or we may be having an increase of treasure trove.

Electric Heaters.—Richmond, Virginia, has electric heaters at work, and they will shortly be fitted on the cars of the electric railroad. The office of the company is heated by this means at the present time. The heaters are connected four in series, the street wire being tapped to supply the current. The current is turned on in the usual way, with a small switch in the room, and the electrical energy required is about three-quarter h.p. for a heater to warm a room 15 ft. square. The double conversion of heat into electricity and back has a very low efficiency, and will have a very limited use. Railway carriages are, perhaps, as good an example as any, as a small, constant, and harmless source of heat is required. The energy might be obtained (as now for electric light) from the axle of the carriage. For the electric trams the main current might be available for winter use.

Thomson-Houston Company.—The Thomson-Houston Company of America are doing big business. They have fitted up 150 lighting stations for local companies during the past year—that is, at the rate of three lighting stations per week, many being towns of less than 5,000 inhabitants. They have fitted 37,000 arc lamps; 78 stations, taking 48,000 incandescent lamps, and 23 stations with 11,000 lights, with alternating apparatus. This is not including private buyers, which would make the amount nearly double. For the New York extension of lighting they will supply 2,250 arcs, with the probability of doubling the number. Three companies are doing this extension work in New York, who between them will require this number of arcs, the manufacture of which will be by the Thomson-Houston Company. This is besides about 3,000 arcs at present running in Brooklyn.

Electro-Plating. We have received a copy of the second edition, carefully revised, with additions, of Mr. J. W. Urquhart's "Electro-Plating: A Practical Handbook." It is clearly written, well arranged, and is aimed to obtain, with the greatest possible simplicity of language, the providing of working directions applicable to the practice of the plating-shop, and to the requirements of amateurs. Electro-plating is gaining a continually-increasing practical value in commercial fields, and has, besides, a fascination for amateurs, by the ease and beauty of its results. In this work we have not a mere text-book compilation, but a practical treatise, carefully worked out from the author's own experience—exactly the kind of book for technical use we are often asked for in various electrical departments and are not always able to mention. The whole of the details necessary for plating by batteries is gone into, with practical directions for each process: the deposition of copper, gold, silver, and nickel being described in separate chapters. The new processes of nickel plating are fully described, and the use of dynamo machines is also carefully considered.

Barcelona. The magic fountain, which was seen for the first time in the Health Exhibition in 1884, and later in the Inventions and Colonial Exhibitions, and which has been reproduced in Liverpool, Staten Island (New York), and also at the Glasgow Exhibition of the present year, is attracting great notice in the Barcelona Exhibition. The fountain at this exhibition considerably excels all the others. The motive power which is employed when all the jets of water and projectors of the electric light are at work is not under 300 horse-power. The fountain was constructed by

the Anglo-American Brush Corporation, who are represented in Barcelona by Don José S. Noble, and the work has been under the management of Mr. William Bates, acting on behalf of the above-named firm. The fountain was completed in a very short space of time, considering the great difficulties which had to be encountered in the course of erection. The effects of the light are produced with very little manipulation of the lamps, and the whole makes an extremely fine and delicate display. Mr. Haworth, the chief engineer, went expressly to Barcelona for the official opening ceremony.

Electric Welding.—Electric welding has now been put on a commercial basis in America, according to the Boston papers. A company has been formed mainly by Boston capitalists, with a capital stock of half a million, which will turn out welding machines. The machines will be sold, but the company has also a royalty on every weld made by their machines. To make this practical, a meter is set upon them all, in the manner of the sewing-machine royalties in America, so that the inventors may reap some of the benefit of the process to the users, besides the mere sale of the machine. The meter has three dials, resembling those on a gas meter, and by its peculiar construction it is claimed that it will not register unless a perfect weld is made. These machines will weld anything in the shape of metal. They do not require that both metals shall be of the same material, as iron has been welded to brass in the experiments tried. The machines as they are now built will weld an iron cable or a watch-spring with equal readiness, and it may be even contemplated that propeller-shafts may be welded by this means. It is claimed that the process makes a perfect weld by fusing the metals, and does not burn the metal, as is often the case in the Bernados process.

Summer Course of Lectures.—Prof. W. E. Ayrton, F.R.S., will give a thorough practical course at the Central Institution, South Kensington, on "The Construction, Testing and Use of Electrical Measuring Instruments." This course will include experimental lectures and special laboratory work, and will be specially adapted to the makers of electrical measuring instruments. The lectures will comprise the principles and practice of the construction, calibration, and testing for faults of ammeters, voltmeters, ohmmeters, wattmeters, coulombmeters and ergmeters as used for direct and alternating current systems. The students' practical work will be conducted in a laboratory specially fitted with accumulators, standard instruments, &c., for electrical instrument testing, and they will have the opportunity of examining and practically trying all the more important electrical meters at present in ordinary use. The course will extend over two weeks, and will consist of six lectures, from 8 to 9 p.m., on Mondays, Wednesdays and Fridays in the fortnight commencing on Monday, July 16th, and also of practical work in the physical laboratories, daily, Saturdays excepted, from 2 to 5 p.m., commencing on Tuesday, July 17th. Applications for admission should be received not later than July 6th.

Electrostatic Transformers.—According to the *Elektrotechnische Anzeiger*, No. 16, 1888, Dr. Doubrava, late pupil under Prof. Stefan and Mach, and teacher at the Technical High School, at Prague, has patented transformers in all countries, which are dependent not upon electro-magnetic but upon electro-static induction. The transformers can be used with direct or alternating currents, and for any desirable difference of potential. With direct currents, a "disjunctor," worked by a small electromotor

enables a condenser to be charged from the central station by a high pressure wire, and from the same "disjunctor" the secondary current is produced by means of a second condenser, and any desired reduction of pressure can be obtained. By this transformation, when the speed of rotation of the disjunctor is arranged so that the condenser is charged and discharged at the same instant, not the slightest spark occurs. With alternating currents, two plates are charged by the high-pressure wire, which influences two other plates, and from the latter the secondary current is obtained. The efficiency is said to exceed that of the electromagnetic transformers, and the system is shortly to be introduced in practical work for electric lighting. We shall be interested to hear whether anything practical comes of this invention, which professes to be an entirely new departure in electric light transformers.

Electromotive Force of Cells. M. Meisler, an Austrian physicist, has measured the electromotive force of various cells with the aid of Siemens' Universal Galvanometer and a standard Daniell cell. He has communicated the following results to the Academy of Sciences at Vienna, which will be useful for reference:

	Volts total E.M.F.
Daniel standard cell	1.06
Grove	1.62
Bunsen	1.77
Bunsen chromic acid	2.18
Grenet	2.02
Smee	1.06
Lalande-Chaparon	1.17
Leclanche	1.68
Marie Davy	1.50
Warren de la Rue	1.07
Naudet	1.65

M. Meisler has also studied the variations of potential during charge and discharge of the various parts of the Plante accumulator, of which he gives the total E.M.F. as 2.2 volts. During discharge, the difference of potential between the positive electrode and the acidulated water diminishes in a regular manner, until the E.M.F. of the element has fallen below half its normal strength. On the other hand, the difference of potential between the negative electrode and the liquid diminishes rapidly, and even changes its sign at the end of a sufficient period of time.—*Revue Scientifique.*

Barnet.—The preparations for the lighting of the town of Barnet are proceeding, but there has been some hesitation on the part of the authorities as to the power of the lamps. The incandescent system was decided upon for the street lighting, and 16 c.p. was thought to be enough, being as much as the present lamps. Mr. Joel, however, has been trying to convince them that 16 c.p. lamps will prove a failure, as was certainly the case at Leamington, and proposes 32-c.p. lamps, with a few stronger lights at main corners, and experimental trials were made last week to test the power of the lamps. Mr. Joel has secured the sole right for three years, with permission to use poles in the streets for the first twelve months, after which all wires are to be underground or at back of the houses. Besides the sole right for three years, he has stipulated that he is to have continual equal right with others at the expiration of this term to continue the lighting, if he so desires. The price fixed is £2. 14s. per 16-c.p. lamp per year, lighted from dusk to 12.30 a.m., and £5. 2s. till dawn; 32 c.p. double this price, and additional light in proportion. It is proposed to put in three engines eventually, one of which will be first installed. This will be 20 h.p. nominal, and the lamps will be in parallel series, fixed on

special lamp-posts, with properly-designed reflectors for utilising the light to the best advantage. These lamps are to be lighted till 12.30, but the three larger lamps at a reduced light will be required all night, and to light these upon the same wire Mr. Joel proposes to insert a magnetic bye-pass to each of the main groups, which will drop when the speed of the engine is allowed to fall, leaving only the corner lamps alight, which will then be fed from a storage battery charged during the daytime. Further additions will, no doubt, be made for private lighting with transformers, as the demand increases, but the street lighting will be first carried out.

Thunderstorm Committee. The first report of the Thunderstorm Committee of the Royal Meteorological Society "On the Photographs of Lightning Flashes," which has been drawn up by the Hon. Ralph Abercromby, F.R.M.S., has just been issued in pamphlet form. According to the results received, the typical forms of lightning are grouped under the headings of stream, sinuous, ramified, meandering, beaded, and ribbon lightning. Some very interesting photographs of the various types of flashes of lightning are reproduced. The society asks the cordial help of any interested in the question, either by sending copies of photographs already taken, and by endeavouring to take them, or by inducing others to do so. The results may be sent to the Secretary of the Royal Meteorological Society, at 30, Great George-street, Westminster. It may perhaps be well to mention that the photography of lightning does not present any particular difficulties. If a rapid plate and an ordinary rapid lens with full aperture be left uncovered for a short time at night during a thunderstorm, flashes of lightning will, after development, be found in some cases to have impressed themselves upon the plate. The only difficulty is the uncertainty whether any particular flash will happen to have been in the field of view. A rapid single lens is much more suitable than a rapid doublet, and it is believed that films on paper would effectually prevent reflection from the back. The focus should be that for a distant object, and, if possible, some point of landscape should be included to give the position of the horizon. If the latter is impossible, then the top of the picture should be distinctly marked. Any additional information as to the time, direction in which the camera was pointed, and the state of the weather, would be very desirable. The Society are hoping, now that the thunderstorm season is approaching, that many photographers, both amateur and professional, may be found willing to take up this interesting branch of their art.

Italian Exhibition. The lighting at the Italian Exhibition, which is entirely on the Thomson-Houston system, has been considerably extended beyond the first requirements, and is admitted by both exhibitors and promoters to be all that is desired. The installing of the machinery was a very quick piece of work—only five days was allowed after the roof of the shed was on. The main galleries and refreshment rooms have 190 arc lights; the grounds and panorama 45, and the new annexe 20 arcs. The arena lately used by the Wild West is being fitted up as the Coliseum at Rome, this has 35 arc lights. Very shortly this will be opened for representation of Roman games, gladiator fights, and races. In the Marionette Theatre the incandescent lamps are being increased to 170, and the Welcome Club (a most luxurious, handsome, and convenient institution for exhibitors and their friends) is elegantly furnished by Messrs. Lang, Wharton, and Down with 60 incandescent lamps in burnished copper fittings.

An ingenious arrangement, used by the Thomson-Houston system, is shown in the engine-room offices and other places on the high potential wire. It is often required to put in a few incandescent lamps. When this is the case, a lamp is inserted in the main circuit, taking an 8-ampere current. These lamps are made for 8 volts and 32 c.p., or 16 volts and 64 c.p., or 32 volts and 125 c.p., and can be inserted wherever desired in the arc circuit. The bye-pass for these is as simple as it is ingenious. The lamp is screwed into a socket, which communicates with the wire, but is only kept from short-circuiting by a thin piece of tissue paper soaked in paraffin. If the lamp breaks, this is ruptured by the main current, and the lamp is therefore cut out. On replacing the lamp by a new one, this latter does not light until the two plates are separated; a new piece of paper is slipped in, and all goes on as before. In America, the Thomson-Houston Company use these lamps by themselves largely in street lighting on a single high-tension wire, a small indicator at the station shows immediately if any lamps are out, and the attendant can then go round the circuit and replace them. We describe the Thomson-Houston incandescent dynamo used for this installation, with illustrations, elsewhere in our columns.

A New Electric Standard.—M. Marcel Deprez has devised an instrument for giving at will an invariable quantity of electricity—for example, the coulomb. It consists of a glass tube of U shape, having its two legs closed and terminated by glass bulbs of much larger volume than the cylindrical parts. One bulb and its corresponding leg is filled with water acidulated with phosphoric acid. The second leg contains also some liquid below, but for most of its length it, and the ball ending it, is filled with air at a fixed pressure. The branch filled with liquid has four electrodes face to face in pairs, two at the upper part of the ball, and two in the cylindrical part a little below the lowest point of the ball. If an electric current is sent through these last, the water is decomposed, and the mixture resulting from the decomposition accumulates in the upper part of the ball, whilst the liquid is forced up the second branch, compressing the air in it. If the point of departure of the liquid column in the second branch is noted as well as the point it stops at when the current is stopped, all the elements necessary to know the quantity of electricity expended to produce the mixture of gases are forthcoming, and it is easy to see that if the volume of this mixture, measured by the ascension of the liquid in the second branch, is always the same, the quantity of electricity necessary to produce it will be equally invariable, whatever be the temperature of the instrument, provided it be the same in both branches—a condition easy to realise. The barometric pressure and hygrometric state of the air have evidently no influence on the results, since the tube is sealed like an incandescent lamp. In short, the apparatus produces at will a quantity of gas corresponding to the invariable quantity of electricity taken for standard, all the operation being the observation of the scale on the branch of the tube, and there being no correction to make. In order that the apparatus may continue to act indefinitely, the water is reformed at each operation by a spark passed through the detonating mixture of the gases in the ball. For this purpose the other pair of platinum wires is provided. The instrument may serve for the standardising of electric measuring instruments. It has been tested with great care by M. Minet, one of the engineers of the Creil experiments,

and its indications compared with the ordinary voltmeter, and found to be fully reliable.

Thermo-Batteries. We publish this week an interesting and valuable communication by Mr. J. W. Swan upon Raub's thermo battery, discussing the points under which its use may or may not be economical. Lord Rayleigh, at the British Association, has given what has proved almost a "quietus" to the question of thermo-batteries upon the score of efficiency, judged from standpoint of the laws of thermo-dynamics, stating that, as a heat engine, for the limits of heat employed, the thermo battery can never give a high efficiency, even when compared with a steam-engine. Prof. Silvanus Thompson, however, has pointed out that the thermo-battery is not to be judged solely as a heat-engine, and that the bare statement as above does not necessarily fully apply. The heat in the conversion of energy which takes place in the generation of electricity in the thermo battery, or at least that portion of it which is so converted, never reaches the higher temperature at all; the greatest possible efficiency of the thermo battery is when the greatest amount of heat disappears as heat and appears as electricity. There is this point to be kept in view, as contradicting Lord Rayleigh's result, and confirming Dr. Thompson, that the efficiency of the human body, or of a horse, is greater by far than the greatest possible efficiency judged solely as a heat-engine. Experiments have been made taking the weight of fodder consumed and the corresponding work accomplished by animals, and the result showed a far greater efficiency than that possible from the temperatures judged solely upon this law of thermo-dynamics. The question seems to point to the human body, and all animal power working upon other laws than that of the heat-engine—namely, that of the thermo-battery; and if we could prove that the thermo-battery has a possibility of a greater total efficiency than the boiler-engine-dynamo combination, the greatest stimulus would be added to the study of this means of generation. If the total efficiency possible, with a perfect heat-engine, is less than 10 per cent., of which we realise usually only about 10 per cent., and the total possible efficiency, with a thermo-battery, might be, say, 80 per cent., of which we at present realise only 2 per cent., this greater possibility will not be long in having advantage taken of it. Upon this subject we append the following clear and explanatory note by Prof. Perry, F.R.S., setting forth the result of the law of thermo-dynamics in the case of steam engines and gas-engines: "We can prove that the greatest possible efficiency of any heat-engine cannot exceed $\frac{T_1 - T_2}{T_1}$, where T_1 and T_2 are the highest and lowest absolute temperatures of the working substance. T_2 cannot be less than 284 (or $10^\circ\text{C} + 274$). Taking steam of 200lb. pressure per square inch as the hottest which may be used without burning the piston lubrication, this is 195°C . or $T_1 = 469$. The greatest efficiency possible is, therefore, $\frac{469 - 284}{469}$, or, $\frac{185}{469}$, or 39 per cent. In existing gas engines T_2 is always high, usually more than 774; T_1 is, say, 1,774, and the greatest efficiency $\frac{1,000}{1,774}$ or 56 per cent. The necessarily great losses by conduction and radiation reduce these numbers very much indeed, so that the efficiency of the very best steam engine and boiler is never greater than 15 per cent., and about the same for the very best gas-engine. Indeed, 10 per cent. is the common figure for good engines."

A NOTE ON RAUB'S THERMO-BATTERY.

The following is the substance of some communications which we have recently had with Mr. J. W. Swan, M.A., on the subject of Raub's thermo-battery, illustrated and described in this paper on April 13.

In spite of the opinion, which has obtained large acceptance among scientific men, that the direct conversion of heat into electricity can never be an economical process, there nevertheless appear from time to time the results of fresh attempts at the solution of this possibly insoluble problem, and some of these are at least sufficiently interesting to deserve notice.

We are made aware of one of the latest of these attempts by a prospectus issued by Fuess, of Berlin, descriptive of "Raub's Patent Thermo-Battery." Looking over this prospectus we are struck with what appears as a distinct sign of progress in the development of this species of electricity generator—viz., the largeness of the current producible by Raub's pile as compared with previous efforts. The apparatus advertised is of three sizes to give a current of 10, 20, and 40 amperes respectively. Each of the three sizes is built up into a pile of 50 couples, and has an E.M.F. of 3 volts.

The three volts E.M.F., coupled with the large current, points to electrolyzing and operations of that kind as the special purpose for which it is intended the thermo-battery should be used, and for such purposes there is no reason to doubt the statement of the maker that it is both efficient and economical.

Let it be granted that only something like 2 per cent. of the energy of the heat applied to a thermopile is converted into electricity, and that ten times the effect could be got out of the heat by means of a dynamo, it still remains a fact that it is a more economical generator of electricity than the ordinary zinc consuming battery.

It may be worth while to go over the figures, and, since it is still seriously proposed to light incandescent lamps by primary batteries of various kinds, to inquire, without going into minute detail, what it would cost to light incandescent lamps on this discredited principle.

For this purpose, we will take the largest size of Raub's battery, which consumes 33 cubic feet of gas per hour and an E.M.F. of 3 volts, and gives a current of 40 amperes. We will assume that it is most efficient when the resistance in the useful work part of the circuit is equal to the resistance of the pile itself, and that therefore the available E.M.F. is $1\frac{1}{2}$ volts, making a product of 60 watts. To obtain at this rate 1 e.h.p. (746 watts), the apparatus—and the gas consumption—would have to be multiplied thirteen times, the gas consumed per hour would therefore be 429 cubic feet. One e.h.p. would therefore cost 1s. 1d. with gas, at 2s. 6d. per 1,000 cubic feet. At 1s. 8d., which is the price of gas at Newcastle, it would cost 8½d.; and with Dowson water gas, at 2½d. per 1,000 cubic feet ($\frac{3}{4}$ times as much as of coal gas being used), the cost of an e.h.p. hour would be reduced to 4d.

But there is reason to believe (see a paper communicated to the Iron and Steel Institute on May 9, 1888, by Mr. A. Wilson, and based on very extensive practical working) that heating gas, of the nature of Dowson's gas—a mixture of hydrogen, carbonic oxide, carbonic acid, and nitrogen, obtained by blowing a mixture of steam and air through a column filled with fragments of carbon heated to incandescence—can be produced on a large scale at the cost of ½d. (one halfpenny) per 1,000 cubic feet, when the coke or coal employed in the process is 6s. per ton. As 1,500ft. of this gas would suffice for the production of an e.h.p. for an hour with Raub's thermo-battery, the cost at this rate would be ½d. per e.h.p. This degree of economy is of course not realisable except where the mixed water and produced gases are obtained on a large scale and with cheap coal.

Burnt in an ordinary gas-burner, 3 c.p. is produced for every cubic foot of gas. The 429 cubic feet of coal gas supposed to be required to produce 1 e.h.p. hour through the thermo-battery and giving, say, eight 16 c.p. lamps, would give, therefore, in an ordinary burner 1,287 to 1,300 c.p., six to seven times the amount of light. But for the purposes of comparison we ought, perhaps, to take the

best light that each can give—namely, the arc electric light, and the Wenham or Siemens gas light. In an arc lamp undoubtedly 1,000 c.p. can be obtained, often much more. Recent experiments have been made which go to prove that half a horse power can be made to produce 1,000 c.p. in an arc lamp. With this extreme result, we might take 2,000 c.p. per h.p., and with the Wenham or Siemens gas light, giving 5 c.p. per foot of gas, for the production of 100ft. of gas, we have also 2,000 c.p.

Used in a gas engine, and with the power applied to a dynamo, this quantity of gas would produce ten times the e.h.p. With 150ft. of gas per hour in a gas engine, 3 e.h.p. can be produced, or with 120ft. if the engine is in good condition; taking 40ft. to 50ft. per e.h.p., as against 400ft. to 500ft. used by the battery, we see that the dynamo costs one tenth for gas. The first cost, also, of the dynamo plant is one third of that of the thermo-batteries. A gas engine would cost £170, and a dynamo producing 2 e.h.p. can be obtained for £36—a total of £206. Twenty six of the thermo-batteries, costing £22. 10s. each, will be required to produce 2 e.h.p., being a total of £585.

Electricity through Raub's thermo-battery is therefore ten times dearer in production than electricity produced by motive power. But often in electro-metallurgy and in many other applications the thermopile will have to compete with the ordinary galvanic battery. In comparing them with galvanic batteries they can boast an advantage, probably in the proportion of two to one, the cost of production of electricity by consumption of zinc being twenty times that of a dynamo driven by a steam engine. They have, besides, the merit of unusual constancy.

In what has hitherto been said no credit has been taken for the lost heat, which is not transformed into electricity. Looking at it this point, it does not seem at all an unlikely thing that an effective combination may be made of a thermo battery and a heating stove, and it is obvious that a successful combination of that kind would entirely alter the aspect of the question of the economy of heat produced electricity.

One of the difficulties hitherto encountered in connection with the use of thermopiles is the destructive effect of the alternate expansion and contraction of the parts, consequent upon repeated heating and cooling. This difficulty, if it exists in the case of Raub's pile, might be met by adopting a suggestion made several years ago by Mr. Higgins, that the heating should be continuous and that the current from the pile should be made to charge a secondary battery used as an accumulator.

It has been reported that M. Heimel, a French electrician, has devised a thermo electric couple with an E.M.F. of 0.18 volt, with a resistance of 0.009 ohm. This is a considerable advance on Raub's couple, fifty of which are required to give three volts. An improvement in this direction will tend to make the apparatus less costly; the present price also might very reasonably be expected to be considerably reduced, if the thermo batteries are made on a manufacturing scale. If they could be produced at one-third the present price they would be equal (in the cost of apparatus) to an engine and dynamo, and this, looking at the development of electrical apparatus in other directions, is not an impossible supposition. There are evidently some uses for the thermo-battery even in its present imperfect form, and with further practical and scientific advances it may play an important part in the production of electricity.

THOMSON-HOUSTON INCANDESCENT DYNAMO.

A new dynamo, of a somewhat curious and novel type, is to be seen at the Italian Exhibition, where it is being used by Messrs. Laing, Wharton, and Down to supply the incandescent lamps in the Welcome Club and the Marionette Theatre. This is the Thomson-Houston incandescent dynamo, the only machine of the kind at present in England. This type of machine has been manufactured commercially for some time in America, but the one now running at the exhibition is the first sent over here.

The Thomson-Houston incandescent dynamo bears some considerable exterior resemblance to the arc machine of

that name, and, like it, has distinctly novel points in its construction from that of other machines. It is compound-wound, but not in the manner covered by the Brush patents. The general appearance of the machine is seen in the accompanying illustration. The field magnets are shunt-wound with fine wire, in the ordinary way of dynamos, and the armature is spherical as in the

Thomson-Houston Incandescent Dynamo.

Thomson-Houston arc machine. The series coils, however, instead of going round the field-magnets, are led off in two separate coils, between the poles of the magnets, and surrounding the armature. The main current passes through these coils in a divided current, half in each coil, and the magnetic induction furnished by these coils dis-

Series Coils of Thomson-Houston Incandescent Dynamo.

turbs the field of the shunt magnets in proportion to the strength of the current flowing, without affecting the actual strength of the magnets in the usual way. In this manner it compounds for any alteration of load. The appearance of the coils, which are just seen in the first illustration, is better indicated in the second woodcut. The top half of

Diagram of Winding.

both coils pass over the armature—towards the left at the top and to the right at the bottom, the two separate cables dividing at one junction, and combining at the other. The general arrangement of the parts is shown by the diagram of connections showing the shunt and series coils.

This machine runs very steadily, giving very little trouble, and compounding for any number of lamps from

1 to 120. It is wound for 100-114 volts, a small regulator at the top cutting out some of the shunt coils, allowing of an adjustment, if necessary, to the extent of 14 volts, to allow for difference of speed. The commutator is quite smooth, and no sparking occurs. Of course, the automatic regulator present on the arc machines is not needed.

MOTOR WORK IN ENGLAND.

The production of motors in this country is proceeding apace, and although we cannot boast of the great development that has taken place in this branch of electrical engineering in America, where the factories for motors are as large as those for the production of dynamos, yet we can chronicle greatly increased activity, and the promise of the same development of large applications of this method of communicating power that has taken place in bygone years with other similar discoveries. Messrs. Immisch and Co., whose works in Kentish Town we have lately visited, are exceedingly active in all kinds of motors, large and small. They have in hand six motors to be used on the North Metropolitan Tramway Company's Barking line. A tramcar fitted with one of these motors has been running for some time on this line, and has given complete satisfaction. This type, of which we give an illustration, showing the sprocket wheel gearing, is driven by accumulators carried on the cars. Two 100 h.p. dynamos for charging the batteries for this work are also being made by Messrs. Immisch and Co., and the number of tramcar motors to be employed for traction will be greatly extended after the first trials.

Tramcar Motor.

The tendency in modern engineering is to larger and larger types of machines as our knowledge of their construction improves, and the ability to build them to design with out previous experimenting is attained. Sizes of electric motors, which would have been thought marvels a few years ago, are now ordered without much hesitation and manufactured without much difficulty, and we may confidently look to types of motors comparable in power to our large modern steam engine being satisfactorily produced as the demand for them arises. Messrs. Immisch are at present constructing two large motors for Messrs. Locke and Co., of Normanton. These motors weigh about four tons each, and will develop up to 75 h.p. when worked to their greatest power, though usually required for a regular output of 50 h.p. The field magnets for these motors are of very large size, and for the double purpose of ease of conveyance and ventilation are made in separate sections. The motors themselves are too large to go down the shaft, at the bottom of which they are to be fixed, and will therefore be sent in parts and fixed together at the bottom. They will be used for hauling coal. The dynamos for supplying the current to these motors are of similar design, weighing a little more—namely, 4½ tons. The dynamos will be fixed at the pit mouth, and the current connected by cables down the shaft. Two large motors have previously been supplied for pumping the water from the pit, and the further order for hauling apparatus that has been secured indicates clearly the satisfaction this method of working gives the colliery proprietors.

With series motors—that is, constant current motors in series with lamps—not much seems to be doing in this country at present. Isolated plants, where a constant current is used for arc lamps, do not seem to be, as a rule,

much in need of a motor, and those stations running a constant current do not advocate the use of motors in series with their lamps, desiring to keep the light as steady as possible. Messrs. Immisch, however, have a type of constant current motor which they have manufactured in small quantities for some time; amongst others, one is running satisfactorily in the West of England, and one at Sheffield. This motor has an ingenious method of short-circuiting the current when the motor is not required. A pair of governor balls regulate by a lever arm a series of resistances, or rather the coils of the field magnets, and upon the speed of the motor falling the regulator touches a spring, which causes a copper bar to fly out and short-circuit the machine.

In small motors Messrs. Immisch are continually busy, and keep a stock of the more usual sizes. These are produced of two man, $\frac{1}{2}$, and one h.p. The $\frac{1}{2}$ h.p. motor is a very compact and useful little motor, not very much larger than a hat, and weighs 42lb. It stands in any convenient corner, and is used for driving ventilators in factories or engine-rooms, or for other uses.

The question of where it would pay to use a motor, is one to which some attention should be paid. On the discovery of a new method of transmission such as this, many persons are naturally inclined, as occasion arises, to attempt a saving by the use of the improved method. It is only advisable in those cases where a distinct benefit can be produced. For an ordinary manufacturing shop, with a large

$\frac{1}{2}$ h.p. Motor

engine in the basement, the cheaper way for the transmission of power to lathes, machines, or other apparatus, will be in most cases by the usual use of belts and shafting. For a large shop to have a considerable number of small and comparatively costly motors scattered about, one to every machine, with its attendant necessity (even if slight) for care and inspection, would mean not gain, but loss. In cases, however, where an additional shed or factory is to be worked, and spare engine-power is near, it is a question for consideration whether a dynamo, with a length of cable and a motor, would not effectively take the place of another engine with less outlay; and, of course, the familiar example of a factory at some little distance to a fall of water is another situation in which the use of a motor would be most advantageous. But there is usually no advantage in putting in a motor merely to take the place of belts. Messrs. Immisch have a motor running in this way, driving the belts and shafting for two machine shops. The motor mentioned is of the tramcar type, giving usually about 5 h.p. to 10 h.p. It is wound for 160 volts, and takes 50 amperes at a maximum. The weight is 550lb. It has been running with every satisfaction for eighteen months. The original commutator is still beautifully smooth and bright, and has only been lightly skimmed once in the lathe. The brushes usually last about three months, and the motor is practically in the same condition (except for a little fresh paint) as when it was started.

The works of Messrs. Immisch themselves constitute a small power distributing station, several electric motors being hired out in the neighbourhood, the current being supplied from a dynamo, worked by the Marshall engine (indicating 120 h.p.) they have for their own works. A small

motor works a ventilating fan for their engine room, and a similar motor is used in the smithy. The printing machine at the back of Messrs. Immisch is run by a motor supplied in the same way, the rent of which the printing firm find considerably less than the cost of a steam or of a gas engine. Power is also supplied to several other small machines.

ELECTRICAL POWER ON TRAMWAYS.

In our impression of the 8th inst. we published a paper on the transmission of electric power by Herr Coerper, and an editorial article on electric tramways. In the former the author describes a form of motor applied to a tramcar, the object of the arrangement being the prevention of the necessity for using too big a current when starting, or to enable the motor to develop its full power when either starting the car, or when propelling it on an up gradient. In our article we called attention to the fallacy which underlies Herr Coerper's assumptions concerning the

device he describes. With the object of running the armature of his motor at a high speed when the car is starting, he mounts his field magnets loose upon the armature spindle so that they also may rotate. Thus, when the field is left perfectly free, it rotates round the armature, and the car axle, with the armature stands still. On the other hand, when the field is prevented from revolving by means of a brake, the armature must revolve unless the resistance to its rotation is too great. Between these two extremes Herr Coerper proposes to obtain variable relative velocities for armature and field by permissive rotation of the field. He proposes to permit the field to slip at a greater or lesser velocity against the resistance of a brake. As we then pointed out, there was no gain whatever in this, for instead of the loss of speed in the armature being accompanied by a gain in turning moment on the car axle, the exact equivalent of the possible gain is thrown away in useless work upon the frictional brake surfaces. Since then we have referred to the *Electrical Engineer* of September, 1886, in which we published a short paper, which was read before the British Association by Mr. W. Worby Beaumont, describing a new system of imparting a variable velocity, and as one of the forms of the apparatus designed under the system was intended for tramcar work, perhaps we may usefully recur to its main features. The first object was to obtain the variable velocity without the loss of work, such as that which occurs with Herr Coerper's brake. The leading feature of the apparatus is the use of

what at the time was a new mechanical device, consisting of a hollow cone, mounted so that in one plane the surface of the cone and of the spindle upon which it was mounted were always parallel. Cones so mounted are shown on the accompanying engraving, as published in our impression above mentioned, and in which Figs. 1 and 2 show the cones as driver and driven by means of a belt. In Fig. 4 the cone is shown employed in controlling the rate of variation in variable velocity or epicycloidal gear. Upon the shaft, S, which might be an extension of the motor spindle, is mounted the cone, K, in such a manner that it may be moved along the shaft, S, by a fork on the collar, P. On the same shaft are mounted loosely the internally geared wheel, A, and the externally geared wheel, B, which is also loose, and carries a stud axle, G, upon which runs the pinion, D. The pinion, C, is fixed to the shaft and communicates not on to the wheel A through the pinion D, so long as the wheel B is held. In Herr Coerper's arrangement the wheel B is held by a brake or allowed to slip therein. In the device shown in Fig. 4, the wheel B is held by the pinion E, fixed to the spindle, H, which carries also the wheel F. This wheel F bears upon the cone, except when the maximum speed is desired for A, when it is held fast by a brake. If any change in velocity is required, the brake is removed and the cone, K, by the same movement brought into contact with the wheel F. This wheel is thus put into motion, and the pinion E permits the wheel B to rotate at a speed which depends upon the diameter of the part of the cone brought into contact with F. By this means it will be seen that a variable circuit is completed between the wheel B, loose upon the shaft, and the cone, K, fixed thereto, and the work done upon pinion E, which replaces Herr Coerper's friction brake, is put back into the shaft, S, by means of the cone. The teeth, J on A, are chain gear teeth. Fig. 5 shows the direction of rotation of the shaft and wheels, A, B, C, and D. Fig. 6 only shows an epicycle train instead of the cyclical train shown in Fig. 4. We may say the whole apparatus is fully described in Patent Specification, No. 5,736, of 1886.

WOODHOUSE AND RAWSON'S DISTANT ELECTRIC GAS LIGHTER.

We illustrate herewith the distant electric gas-lighter of Messrs. Woodhouse and Rawson, recently used on Nairn Pier and other places. The method of use is ingenious, and

Electric Gas Lighter.

very simple. Three or four Leclanché cells are connected to the distant point, at which is fixed the apparatus shown in Fig. 1, which contains a small electro-magnet and ratchet wheel, fixed to an ordinary burner. The action of the magnet temporarily breaks the circuit, and in so doing touches a short spring wire to the gas burner. A coil of

ordinary No. 16 insulated wire, 8 in. long, is interposed in the circuit near the battery. This is a simple primary coil, but the act of suddenly breaking circuit induces a secondary spark, and so lights the gas. The push, Fig. 2, is arranged

Black and White Push for Electric Gas lighter.

with two buttons, white and black. The white push turns the gas on and lights it, the black push turns it out. The apparatus acts practically automatically at any distance.

GASSNER'S DRY BATTERY.

The ideal seems the not impossible in electricity. We have looked for the ideal dynamo, and, apparently, not altogether in vain. If what we learn about Dr. Gassner's dry battery is true, we, perhaps, have here the ideal battery. The principal of Staten Island Academy—wherever that is—says so, and, indeed, we are inclined to agree if the results bear out the statements. But one modification is needed at the outset. Let us whisper to the primary battery syndicates this battery is *not* for lighting incandescent lamps; it is not an electric lighting battery at all, it is for ringing bells. We are told it has rung a bell wound to a resistance of 20 ohms for sixty days continuously, and was not exhausted. It has also driven a primary clock for thirteen months, and still gives forth its current. It is intended to replace the Leclanché cell, which is fragile, and liable to spill if broken, and does not last so long without attention.

Dr. Gassner's Dry Cell.

Z Zinc. O Oxide of zinc in gypsum. C Carbon Cylinder.

We have had so-called dry cells before, whose action depends upon the saturated free moisture of a mixture in the cell. In Gassner's cell the necessary moisture is contained in the battery in chemical combination, and not in the form of a free liquid. This combination consists of oxide of zinc in gypsum.

The glass containing cell is done away, and the outer cell consists of the zinc element itself in the form of a solid zinc cylinder. This has insulating material inside, covering the bottom, and the carbon block rests upon this, the space being filled with the special preparation, and the top being securely cemented up. Such a cell can be used in any position, and is not affected by alteration of temperatures. When at rest, no chemical action appears to occur at all, and the porous mass does not form any deposit on the zinc—a common fault with dry batteries, and one which tends to rapidly increase the resistance and decrease the current.

When exhausted, the battery will act as a secondary cell or accumulator, and may be renovated by passing a current from Bunsen's cells, tests taken by Prof. Gerard, of Liege University, showing that 92 per cent. of this energy can be recovered.

The following tests have been made by Prof. Gerard:—

E.M.F. at starting	1.508 volts.
Internal resistance	0.21 ohms.

The element was put on short circuit.

Time.	E.M.F. (Daniell's.)
0	1.508
5 seconds	1.36
1 minute	0.935
2 minutes	0.800
3 "	0.682
4½ "	0.680
5 "	0.632
10 "	0.525
15 "	0.133

On open circuit it recovered itself as follows:—

Time.	E.M.F.
1 minute	0.611
3 minutes	0.791
5 "	0.850
3 hours 30 minutes	1.265

After being put again on short circuit for eighteen hours, the E.M.F. fell to 0.1015 volts, furnishing altogether 45 e.h.p. (3,376 kilogrammetres) of work. Here the regeneration by means of the charging current was resorted to, with a current of 5 amperes, and resulted in a rise in thirty minutes to 1.680 volts, and after four hours further charging with 1 ampere it showed an E.M.F. of 2 volts. It was here discharged on short circuit, falling in fifteen minutes to 0.77 volts, and after eighteen hours to 0.1 volts, returning, as before mentioned, 92 per cent. of the energy received. The regenerated element is even better than the freshly-formed element.

The length of time this battery can be run continuously, its portability and its immunity from damage, should make it an exceedingly useful addition in its special department.

THE TESLA ALTERNATE CURRENT MOTOR.

Dr. Louis Duncan gives the following further note on the Tesla motor:

"Since writing my last note on this motor Mr. Tesla has read an interesting description of his system before the Institute of Electrical Engineers, and in his answer to the note referred to he has further described his motors. The study of both of these papers has increased my admiration for the simplicity and success of his system.

"The motor discussed in my last note was of the synchronous type with two short-circuited coils at right angles to one another. Further, Mr. Tesla in his paper before the Institute of Electrical Engineers states that 'in a general distributing system of this kind the following plan should be adopted

The motors operated from this generator should be of the synchronous type, but possessing sufficient rotary effort to insure starting.' So I will reconsider the statements I made in the previous note with reference to this type, and try to see if they should be modified. With respect to my views as to the theory of such a motor, they look at the phenomena from a different standpoint from that taken in Mr. Tesla's paper, and an unfortunate misprint ('It' for 'I,' the symbol used to represent current) greatly

obscures the meaning. Apart from this, my conclusions were that it was doubtful if such a motor would start under load—meaning to attain its proper number of revolutions—that if a load of great inertia be suddenly applied so that the motor is called on for more than its maximum load, it will stop or take up some slower speed, and finally, that the currents do not decrease in proportion to the load. Now, the first two questions can be settled so easily and simply by experiment, that it is hardly worth while attempting to evolve reasons for believing one way or the other. The way I would look at it is this. The motor combines a synchronous and non-synchronous part. The former does little work until the motor reaches its normal speed; the latter does considerable work until the motor reaches a speed lower than the normal by an amount depending on the load. Now, how is the speed to jump from this lower value, at which equilibrium is reached, to the normal value? It might do so in a number of cases where the inertia is great, in others I must confess to doubts. As to the second point, my objection follows directly from what I have said above.

"With respect to the consumption of current at small loads, I think that in any synchronous motor, the effect of decreasing load is simply to decrease the difference between two quantities of work—one plus, the other minus—that the motor does. If this is the case, the currents should not vary in proportion to the load, but should be greater in proportion with smaller loads.

"With respect to the non-synchronous motors, however, I have very little but admiration to express. I cannot help thinking that they can be governed without resorting to synchronism, and in this case they will have advantages that will greatly aid in the advance of electric distribution.

"Finally, I must confess to some disappointment that no data has been given as to the performance of Mr. Tesla's motors. One cannot, of course, expect from machines that are just emerging from an experimental state the efficiency and output that they will finally attain, but a few curves of the currents in the magnets and armature coils under different conditions would tell us more of the possibilities and directions of improvement than could any amount of discussion.

"In the meantime, I would congratulate Mr. Tesla on the discovery and application of a novel means of obtaining continuous rotation from alternating currents, and I shall watch the further development of his system with interest."

INDICATOR MAGNET.

We illustrate below an indicator magnet devised by Mr. J. T. Todman, of Messrs. Mayfield and Co., which presents some points of interest on account of the ease and certainty of its movement. The white card bearing the figure is shown in back position in the cut; it is mounted on a

Indicator Magnet.

revolving arm actuated by a spring, and is released from a projecting stud when the magnet acts upon the armature. The core of the magnet is hollow, and the stud is carried below into the inside of the magnet, which thus acts also as a solenoid, starting the motion of the armature at the slightest contact of the circuit. This apparatus, mounted with a small dry battery, makes a very cheap and effective indicator.

THE ELECTRICAL ENGINEER.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** for a series can be arranged on application.

"**SITUATIONS VACANT**" and "**WANT PLACES**" Advertisements will be charged at **THREE WORDS for ONE PENNY**, with a **MINIMUM** charge of **SIXPENCE**.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom.	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, 139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, Esq., President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of W. H. WOLLASTON, M.D., F.R.S., and on April 20th we give that of SIR HUMPHRY DAVY, F.R.S., whose fame as an electrician is still more prominent than that of WOLLASTON. Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of PROF. D. E. HUGHES, F.R.S.

DETAILS.

Wellington's success is said to have been largely due to his attention to details. Nothing seemed too large or too small for him to consider. The engineer who plans an electric light installation has somewhat the character of a general in that he has to arrange satisfactorily a number of details, which, acting harmoniously together, result in a successful scheme, while, on the other hand, if the parts are not carefully considered in connection with the whole, trouble is likely to arise and failure result. There is no royal road to success, and it must not be expected that a number of pieces of apparatus brought together at haphazard when put together will give a very satisfactory performance. No rule is said to be without exceptions, and certainly there are men both amongst those who call themselves amateurs and amongst those who are strictly professional, who are adepts at making the most incongruous materials and apparatus suit their requirements and work admirably. The real engineer will no more think of makeshifts in permanent work, than the general will advise declaring war against a strong power when there are no soldiers except militia, and no guns except the antediluvian Brown Bess. There is hardly an engineer of repute but who has had to contend against "failure." The word has an ugly look, but it remains, and nothing can hide it or even put it into the background. A single failure is more damaging to a young industry than can be compensated for by a hundred successes. Look at our contemporaries devoted to the gas industry. Week in and week out they hunt out every failure they can find, and pervert the meaning of the criticism of the technical press into something never contemplated by the critic. They fasten and fatten on the failures to our detriment. Though if we are not in error, by far the larger number of failures are due to neglect of details. The dynamo, lamps, and wiring may be perfect; but, to save a few pounds, an engine is obtained from a second-class, instead of a first-class maker. Again, the engine may be of the best make, and the dynamo faulty, or the wiring carelessly carried out, the leakage too great, and the demand upon engine and dynamo greater than they can supply. Usually, however, the failure arises not from any inherent weakness in these, the principal parts of the installation, but in the matter of contacts and cut-outs.

One of the fundamental principles to be respected in an electric light installation is publicity. Nothing should be hidden or put away in such a manner that it cannot be easily examined. A part of the daily routine should be rigid inspection and careful report. We have not yet arrived at that stage of perfection that any part of the installation can be permitted to look after itself. This fact seems to us self-evident, but in several cases that have come under our notice,

both as regards house and ship lighting, the wires have been so built in, that ship or house would have to be pulled almost to pieces to get at them should anything go wrong. In overhead wires breakdowns have occurred through carelessness in not running the wires to the insulators. Cases are well known where wires not damp-proof have been run in places where dampness was the prevailing rule and not the exception. A short time since an engineer stood by watching the laying and insulating of an electric light cable in a trough under the roadway. His description of the scene was one of utter carelessness and incompetency, and that the manner in which the cable was laid must lead to many troubles. We are not sure, indeed, but that he described the cable as being so carelessly laid that in one or two cases he noticed it was not in the trough at all. We were unable to ascertain whether this particular work was by contract or otherwise, but we have no hesitation in saying, from the description of the work given to us, that the last cost of that cable will be greater than the first. There are two classes of breakdowns, one of which can be minimised, if not entirely eradicated, by the constant attention to details; the other cannot be so obviated, but the former class is immeasurably more numerous than the latter, so that we may rest contented till the latter develops, if we can only get rid of the other. There are cases in which the installation is wilfully injured. Pity 'tis that such an accusation may be made in the latter end of the nineteenth century, but among such instances we may cite the severance of a wire by means of a hatchet, which caused a stoppage of half-an-hour in a town installation. No amount of care can foresee such acts as this; but we may hope that the record will not be further lengthened. Some years ago a well-known master at a public school read a paper before a society of his colleagues, and chose for his text "trifles," arriving at the conclusion that the success of a schoolmaster depended very much upon the attention he gave to "trifles." Without assenting to this conclusion unreservedly, we do really think that the success of an electrical, or in fact any other, engineer depends very largely upon his attention to "trifles," though in this case we should prefer "trifles" to be spelt "details."

CORRESPONDENCE.

DYNAMOMETERS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—At pp. 536 and 537 of your impression of the 8th inst. you describe and illustrate a form of dynamometer, which you mention as White's. I believe you will find that the credit of this invention is due to John Elee. Dynamometers of this form were registered in November, 1849, No. 2090, and were made by John Elee and Co., at the Phoenix Park Iron Works, Jersey street, Manchester, and were more particularly used for ascertaining in mills and factories the power required to drive spinning and other machinery in their places.—Yours, &c.,

229, Norwood road, S.E. W. WORRY BEAUMONT.

DEVICE FOR THE DETECTION OF HOT BEARINGS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In your last issue there appears a note descriptive of a "Device for the Detection of Hot Bearings." Why do not inventors better employ their time than in inventing ingenious devices for which there is no demand? I do not speak alone from my own experience in suggesting that a device to indicate a hot bearing is uncalled for, but also from the long experiences of men whose business it has been to look after engines and machinery. What an engine driver or a machine man wants to know is when any bearing begins to run hot, and by hot I mean hotter than usual for that particular bearing. No two bearings run exactly alike. What might be considered cool for one would probably be dangerously warm for another. What, then, is the good of an indicator which gives a signal at a certain standard temperature? Take the case of a main bearing or a crank-pin, we should have no indication that it was becoming hot, but when the mischief was done the bell would ring. The engine itself would tell us this by dragging. Besides the inutility of such devices, we introduce with them a new evil—that is, they would tend to make engine drivers careless and neglect to pay that attention to the machinery which they otherwise would. The most efficient and reliable detector for hot bearings is the hand, and any man who is fit to be left in charge of an engine will go round as regularly as clockwork and feel the bearings; he thus knows the condition of each one and the probabilities of any of them running hot. I know of an installation which runs twenty hours a day and seven days a week in which hot bearings never occur, but if these automatic detectors were introduced I doubt if it would continue to enjoy this reputation.—Yours, &c.,

London, W.

F. BROADBENT.

INCANDESCENT LAMPS V. FIRE RISKS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Having been away from England for some time past the report upon M. Mascart's experiment relative to the above subject, which appeared in your journal of May 18th last (page 459), only came under my notice this morning, hence delay in writing; but as the subject is an important one, permit me to point out that danger from fire is entirely obviated if a double glass lamp globe is used. This is easily accomplished at about a penny extra cost, by the lampmakers blowing one tube within another of slightly smaller diameter, so as to cover, as it were, an outer shell over the lamp bulb.

I may mention that this class of lamp was patented by me in 1883. The following is the description set forth in the specification—viz.:

"The globe, or bulb, of this lamp is made either of clear or of coloured glass, and is surrounded by a glass globe or covering same in such a manner as to leave a space between the two globes for the passage of air. By these means, the outer globe, or covering, is kept cool, and is, therefore, not liable to be cracked or broken by water dropping upon it. Moreover, the risk of explosion will be diminished, because, should the lamp receive a blow sufficient to break the outer globe, the inner globe will still serve as a protection against the ignition of gas by the incandescent filament."

This special class of lamp has a treble advantage:

1st. It prevents the breakage of lamp bulbs holding the filament by any sudden splashing of water thereon.

2nd. The hollow space between the two globes keeps the outer jacket cool, and thus prevents any injurious effect by undue heat.

3rd. When used as a safety lamp in mines, it tends to prevent explosions by the heated filament not coming in direct communication with fire-damp in case of fracture of bulb.

For high candle-power lamps of 100 c.p. and upwards, the Westinghouse and Seel types, in which double filaments are used, have considerable advantage, as less heat is generated in lamps of this class, but in the new class of lamps now made of the non vacuum type, the bulbs of which are filled with attenuated gases or expansive ethereal vapour, the large bulb, as suggested by M. Mascart, is an advantage, as it holds a larger quantity of carbon-feeding vapour

therein enclosed, and therefore prolongs the life of the filament, and not only tends to prevent air wasting, but also prevents disintegration of the conductors used to produce the light.

M. Mascart has evidently overlooked the value of keeping the lamp bulbs as small as possible if high vacuo is sought to be attained; but as the modern methods of lamp manufacture, according to the present state of the art, have considerable advantages over the old systems, the question of high vacuo is not of such importance, as is generally supposed, now that other discoveries have been brought into practice, as now known and adopted in incandescent lamp manufacture. If you can find space in your next issue, please insert this, and oblige Yours, &c.,

June 28.

ARTHUR SHIPPY.

EFFECTS OF DIFFERENT POSITIVE METALS, ETC., UPON THE CHANGES OF POTENTIAL OF VOLTAIC COUPLES.*

BY DR. G. GORE, F.R.S.

In this research numerous measurements were made, and are given in a series of tables, of the effects upon the minimum point of change of potential of a voltaic couple in distilled water (Royal Soc. *Proc.*, June 14, 1888), and upon the change of electromotive force attending variation of strength of its exciting liquid (*ibid.*), obtained by varying the kind of positive and of negative metal of the couple, and by employing different galvanometers. The measurements were made by the method of balance through a galvanometer, with the aid of a suitable thermo electric pile (Birmingham Philos. Soc. *Proc.*, vol. iv., p. 130, *The Electrician*, 1884, vol. xi., p. 414). The kinds of galvanometer employed were an ordinary astatic one of 100 ohms resistance, and a Thomson's reflecting one of 3,010 ohms resistance.

The following were the proportions of hydrochloric acid (HCl.) required to change the potential of different voltaic couples in water:—

Table I. Hydrochloric Acid.

	Astatic galvanometer.	Between	Reflecting galvanometer.
Zn + Pt 1 in	9,300,000	and 9,388,185	1 in 15,500,000 and 23,250,000
Cd + Pt 1 ..	574,000	.. 637,000	1 .. 1,662,500 .. 1,560,000
Mg + Pt 1 ..	516,600	.. 573,000	1 .. 775,000 .. 930,000
Al + Pt 1 ..	12,109	.. 15,000	1 .. 42,568 .. 46,500

With iodine and the astatic galvanometer the following proportions were required:—

Table II. Iodine.

Zn + Pt between 1 in	2,100,000	and 3,521,970
Mg + Pt .. 1 ..	577,711	.. 643,153
Cd + Pt .. 1 ..	200,431	.. 224,657

With bromine and the astatic galvanometer:—

Table III. — Bromine.

Mg + Pt between 1 in	310,000,000	and 344,444,444
Zn + Pt .. 1 ..	77,500,000	.. 84,545,000
Cd + Pt .. 1 ..	3,470,112	.. 3,875,000

The magnitudes of the minimum proportions of bromine required to change the potentials of the three couples in water, varied directly as the atomic weights of the three positive metals.

With chlorine, the following were the minimum proportions required:—

Table IV. Chlorine.

With the reflecting galvanometer.		
Mg + Pt between 1 in	27,062,000,000	and 32,291,000,000
With the astatic galvanometer.		
Mg + Pt between 1 in	17,000,000,000	.. 17,612,000,000
Zn + Pt .. 1 ..	1,264,000,000	.. 1,300,000,000
Zn + Au .. 1 ..	518,587,360	.. 550,613,022
Cd + Pt .. 1 ..	8,733,586	.. 9,270,833
Zn + Cd .. 1 ..	55,436	.. 76,467

In the case of chlorine, as well as that of bromine, the magnitudes of the minimum proportions of substance required to change the potential of magnesium-platinum, zinc-platinum, and cadmium-platinum varied directly as the atomic weights of the positive metals.

The examples contained in the paper show that the proportion of the same exciting liquid necessary to disturb the potential of a voltaic couple in water, varied with each different positive or negative metal; and that the more positive or more easily corroded the positive metal, or the more

negative and less easily corroded the negative one, the smaller usually was the minimum proportion of dissolved substance necessary to change the potential.

By plotting the results in all cases, it was found that the order of change of potential, caused by uniform change of strength of liquid, varied with each positive metal.

The results also show that the degree of sensitiveness of the arrangement for detecting the minimum point of change of potential, depends largely upon the kind of galvanometer employed.

As a more sensitive galvanometer enables us to detect a change of potential caused by a much smaller proportion of material, and as the proportion of substance capable of detection is smaller the greater the free chemical energy of each of the uniting bodies (Roy. Soc. *Proc.*, June 14, 1888), it is probable that the electromotive force really begins to change with the very smallest addition of the substance, and might be detected if our means of detection were sufficiently sensitive, or the free chemical energy of the uniting bodies was sufficiently strong.

THE "VOLTAIC BALANCE."

BY DR. G. GORE, F.R.S.

A new and simple lecture experiment is to take two small clean glass cups containing distilled water, simultaneously immerse in each a small voltaic couple composed of either unamalgamated magnesium or zinc with platinum, taking care that the two pieces of each metal are cut from the same piece and are perfectly clean and alike. Oppose the currents of the two couples to each other through a sufficiently sensitive galvanometer, so that they balance each other and the needle does not move. Now dip the end of a slender glass rod into a very weak aqueous solution of chlorine, bromine, iodine, or hydrochloric acid, and then into the water of one of the cups. The voltaic balance is at once upset, as indicated by the movement of the needle, and may be shown to a large audience by means of the usual contrivances.

The chief circumstance to be noticed is the extremely great degree of sensitiveness of the arrangement in certain cases. This is shown by the following instances of the minimum proportions of substance required to upset the balance, with an ordinary astatic galvanometer of 100 ohms resistance, and with a Thomson's reflecting one of 3,010 ohms resistance.

1. *Zinc and Platinum with Iodine.* With the astatic galvanometer, between one part of iodine in 3,100,000 and 3,521,970 parts of water.

2. *Zinc and Platinum with Hydrochloric Acid.* With the astatic galvanometer, between one in 9,300,000 and 9,388,185 parts; and with the reflecting one, between one in 15,500,000 and 23,250,000 parts.

3. *Magnesium and Platinum with Bromine.*—With the astatic galvanometer, between one in 310,000,000 and 344,444,444 parts.

4. *Zinc and Platinum with Chlorine.*—With the astatic galvanometer, between one in 1,264,000,000 and 1,300,000,000 parts.

5. *Magnesium and Platinum with Chlorine.* With the astatic galvanometer, between one in 17,000,000,000 and 17,612,000,000 parts. And with the reflecting one, between one in 27,062,000,000 and 32,291,000,000 parts of water.

Every different soluble substance requires a different proportion, and with unlike substances the difference of proportion is extremely great. With solutions of neutral salts, the proportion of substance required to upset the balance is large; for instance, with chlorate of potash, a zinc-platinum couple, and the astatic galvanometer, it lay between one part in 221 and 258 parts of water.

The degree of sensitiveness of the balance is usually greater, the greater the degree of chemical affinity the dissolved substance has for the positive metal, and the less it has for the negative one.

By first bringing the balance with a magnesium-platinum couple and the astatic galvanometer nearly to the upsetting point, by adding one part of chlorine to 17,612 million parts of water, and then increasing the proportion to one in 17,000 millions, the influence of the difference, or of one part in 500,000 millions, was distinctly detected.

* Abstract of Paper read before the Royal Society, June 21, 1888.

PROTECTION OF BUILDINGS FROM LIGHTNING.*

BY PROF. OLIVER J. LODGE, D.Sc., F.R.S.

Lecture II.

I made several assertions last week which it is my business now to justify by actual experiment.

The word "inertia" one uses as conveying a correct general notion of the behaviour of an electric circuit to sudden electromotive forces, a behaviour which is caused by the influence or induction which every portion of a circuit exerts on every other portion. Consider a conducting rod as analyzed into a bundle of parallel wires or filaments, and let a current be suddenly started in all. The rising current in any one filament exerts an opposing force on all the others, and thus self-generated opposition E.M.F., due to induction between the different filaments of the conductor, exactly imitates the effects of ordinary inertia as observed in massive bodies submitted to sudden mechanical forces. For some illustrations of these well-known effects see a letter by Mr. Maclean in *Nature*, vol. 37, p. 612).

The term commonly employed to denote the electrical inertia-like effect is "self-induction," which is becoming gradually shortened to "inductance", its original form when first dealt with by Sir William Thomson was the "electro-magnetic capacity" of the circuit.

Now, since electric inertia is due to a mutual action between the filaments into which a conductor may be supposed divided, it is manifest that the closer packed they are the greater their inertia will be, and that to diminish inertia it is only necessary to separate the filaments and spread them out.

The main count of the inducement against ordinary procedure is, that too much attention has been hitherto paid to conducting power, and too little to inertia. In fact, it is not too much to say that practically nothing but conductivity has been attended to, or thought of, in the erection of lightning conductors.

I want to show that conductivity is from many points of view of hardly any moment, and that the circumstances of a discharge are regulated far more by inertia than by conductivity. I can even show that under certain circumstances high conductivity appears to be an actual objection, and that a stout rod of good conducting copper carries off a flash less well and quietly than a thin wire of badly-conducting iron.

Let us proceed to verify this paradoxical statement at once.

EXPERIMENT OF THE ALTERNATIVE PATH.

The first form of experiment I have to describe is a very simple one. I call it the experiment of the alternative path. It consists in giving a Leyden jar discharge the choice between a certain conductor and a certain length of air, and in adjusting the length of air until it had as lief take one path as the other.

I am not aware that the particular mode of carrying out this simple experiment has any special significance, but, to be definite, I depict, in Fig. 1, the symmetrical arrangement I have most frequently, though not exclusively, adopted.

The knobs marked A are the ordinary terminals of a Volta machine. The jars stand on ordinary wood table, and their outer coats are led to the discharger, B, the distance of whose air-space can be varied. The alternative path, L, is shown by a dotted line. The discharge has to choose between B and L. Sometimes L is absent, and in that case the charging of the jar is quite well effected through the wood of the table; this is the advantage of having the jars imperfectly insulated. At the same time the conducting power of the wood is too low to enable the jars to discharge themselves at all satisfactorily, unless the knobs, B, are within striking distance, or unless some path, L, is provided. The only discharge obtained at A when both paths B and L are absent, is a feeble spitting or intermittent and frequent sparking, very different from the loud report heard as soon as the knobs B are brought within striking distance. But

it is not to be supposed that the B knobs must be as close together as the A knobs in order to permit complete discharge; on the contrary, the B knobs may be almost twice as far apart as the A knobs, and yet the discharge shall be complete and noisy.

It will be understood that the two sparks occur together—a spark at A precipitates, and is the cause of, the spark at B. Not vice versa, for until the A spark occurs there is not the slightest tendency for a spark at B. The two B knobs are at the same zero potential, and may be touched with impunity except at the instant when the flash occurs at A. Remember that the jars are standing on a common table all the time.

Let it be thought that there is anything occult in this mode of obtaining the spark at B, let us subjoin, as Fig. 2, another arrangement of connection, which does just as well, and, in fact, represents the first experiment I tried. The condenser is a very large one of tinfoil and glass plates, with carefully insulated terminals. My object in making it was to obtain a sudden rush of a considerable quantity of electricity (like lightning), and then study its behaviour under various circumstances. I found afterwards that for most experiments an ordinary gallon or even pint Leyden jar served just as well, was much quicker in use, and less dangerous. Moreover, the use of insulated terminals necessitates the continued presence of some alternate path, L, or other, else, of course, the condenser declines to charge.

It may be noted at once that with either arrangement the spark, A, was very loud whenever the spark was allowed to occur at B as well, but as soon as the discharge was compelled to traverse the alternative conductor, L, by putting the B knobs too far apart, then the noise of the discharge was much diminished, not merely because there is now only one spark instead of two, but plainly because, for some reason or other, the discharge meets with considerable obstruction in the wire, whereby its duration is lengthened, and its noise therefore very greatly lessened.

The numbers given below are extracted from a page of the laboratory note book, and refer to an experiment with two Leyden jars, of a size which I sufficiently specify by calling them "gallon" jars, arranged as in Fig. 1. The length of the A spark was maintained at one inch throughout the experiment; or as it happened to be accidentally convenient to measure lengths in tenths of an inch, I will call the A length 10. The B length is variable, being altered until a B spark sometimes passes and sometimes misses.

The first alternative path I show is a length of about 40 ft. of stout No. 1 (B.W.G.) copper wire or rod, suspended round the room by silk ribbon. Its resistance to ordinary currents is very small, between 0.25 ohms. Nevertheless, we shall find that the discharge refuses to take this apparently easy path, and persists in jumping the air gap, B, instead, until the B knobs are separated 14.3 tenths of an inch. This is the critical distance. If they are further apart than this, the discharge chooses the thick copper wire by preference, and its noise or suddenness is then much less.

As a contrast with this, I next try a similar length of fine iron wire (No. 27, B.W.G.), whose resistance to ordinary currents is 33.3 ohms, or 1,300 times as great as the other. We find that the discharge very distinctly prefers this wire to the other. For if the B knobs remain at the distance 14.3 we never now get a B spark, nor do we get one until they have been brought distinctly nearer. The critical spark length is now 10.3. I confess I was surprised at this result.

Let us next try an enormous resistance—a capillary tube of liquid (very dilute acid), giving to ordinary measurements some 300,000 ohms. The critical spark length at B is indeed a little increased by this great resistance, but not much above that found for the stout copper wire. I have not an exact measure of it, but sixteen or seventeen will not be far out. The spark at A now becomes very quiet indeed, pointing to the fact that what we were observing all along was in some sense or other the effect of true resistance, for the unchangeable resistance in the capillary tube gives just the same kind of effects as does the copper or iron wire, only a little more pronounced.

I have suspended three other conductors of about the same length, which it is easy to try in the same way, keeping the A spark-length 10 all the time. The results are here summarised:—

Alternative Path.	Critical B spark length.
Stout copper wire No. 1 R = 0.25 ohm	14.3
Ordinary copper wire, No. 19 R = 2.72 "	13.4
Steel iron wire No. 1 R = 0.86 "	10.8
Ordinary iron wire No. 18 R = 3.55 "	10.8
FL. soft iron wire No. 27 R = 33.3 "	10.3

The copper wires seem to obstruct almost equally, and the iron wires also obstruct equally among themselves, notwithstanding their very different diameters; but the coppers obstruct more than the irons.

There is nothing absolute about these numbers; they are the record of a definite experiment, but their precise value depends on the circumstances of the experiment. It is easy to arrange it so that the iron is less effective than the copper—so that, in

* Dr. Mann Lectures, delivered March 19, before the Society of Arts.

fact, ordinary resistance seems to become of consequence again. This is done by putting a long lead into the A circuit of the jars. But whenever the flash is made as sudden as possible and there seems little doubt but that a lightning flash is very

FIG. 2.

sudden then the order of the numbers is something like the figures quoted.

REASON OF THE ENORMOUS OBSTRUCTION OFFERED BY A GOOD CONDUCTOR.

Now, what is the cause of all this astonishing obstruction offered by good conductors to the sudden rush of electricity? One may express it in a popular way, thus: It is due to electrical inertia, or what is also called "self-induction." A current cannot start in a conductor instantaneously, any more than water in a pipe can start moving at full speed in an instant. Give the water a violent blow to make it move, and it resists like a solid. The blow, if very quick and violent, may burst the pipe, but it will not appreciably propel the water. So, in a manner, is it with electricity. The flash occurs, and the conductor must either carry it off at once or not at all. There is no time to think about it, and the E.M.F. needed to overcome this inertia-like obstruction is so great, that a considerable thickness of air may be burst by it, and the discharge may flash off sideways to anything handy.

Another way of putting the matter is this. A lightning discharge is essentially a varying current. It manifestly rises from zero to a maximum, and then dies away again, all in some extremely small fraction of a second, say 100,000th, or thereabouts. But that is not all, there is a certain amount of energy to be got rid of, to be dissipated, and it may easily be that a single rush of electricity in one direction does not suffice to dissipate all the stored-up energy of the charged cloud. If the conductor is highly resisting, a single rush is sufficient, but if it be well-conducting it is quite insufficient. What happens then? The same as would happen with compressed air or other fluid rushing out of an orifice. If it is a narrow jet, there is a one-directioned blast; but if a wide, free mouth be suddenly opened, the escaping air overshoots itself by reason of inertia, and springs back again, oscillating to and fro till the stored up energy is dissipated. Just so is it with an electric discharge through good conductors. It is not a mere one-directioned rush, it is an oscillation, a surging of electricity to and fro, until all the energy is turned into heat.

This fact is often forgotten by lightning-rod men. They speak as if there were a certain quantity of electricity to be conveyed to earth, and there was an end of it; but they forget the energy of the electric charge, which must be got rid of somehow. If a great weight, or a large reservoir of water, were propped up above one's house, one would not say that the safe thing being to get it down as quickly as possible, it was advisable to knock the props away, or to blow the bottom out of the reservoir; no, one would prefer to let it slide slowly and gradually down a well-resisting channel, so as to disperse the energy gradually.

We will remember, then, that a Leyden-jar discharge through good conductors is oscillatory, and that the oscillation continues until all the stored energy is rubbed away. The oscillations have an enormous frequency: they may be millions a second, for the whole lot of them have to cease during the excessively minute duration of the visible flash. It is well known that a flash is of far less real duration than the persistence of optical impression on the retina would lead one to believe, as is easily illustrated by illuminating a spinning wheel by an electric spark. However fast (ordinarily speaking) the wheel is spinning it appears to be stationary, and the spokes are seen singly and clearly by the light of each spark.

It is for this reason that, although the illuminating power of a powerful flash need not be greater than weak moonlight, its actual intensity while it lasts may exceed strong sunlight, and hence may exert a damaging effect on the retina, and cause blindness.

There is another fact which it behoves us to be aware of. It is one of the unimportance of which the attention of scientific men has but recently been called. Experimentally it has been discovered by Prof. Hughes; theoretically by Mr. Oliver Heaviside, Lord Rayleigh, and Prof. Poynting, for, though the necessary theory is really contained in Clerk Maxwell, it required digging out and displaying. This has now been abundantly done, but the knowledge has scarcely yet penetrated to practical men; indeed, it has not yet been thoroughly assimilated by most physicists. The fact is this. When a current starts in a con-

ductor, it does not start equally all through its section. It begins on the outside, and then gradually, though rapidly, penetrates to the interior. A steady current flows uniformly through the whole section of a conductor, a variable current does not. It is started first at the surface, and it is stopped first at the surface.

Remembering the rapidly oscillating character of an electric discharge, remembering also the fact that a rising current begins on the outside surface of a conductor, we perceive that, with a certain rate of alternation, no current will be able to penetrate below the most superficial layer or outer skin of the conductor at all. In the outer skin, of microscopic thickness, electricity will be oscillating to and fro, but the interior of the conductor will remain stolidly inert and take no part in the action.

Thus we arrive at a curious kind of resistance, caused by inertia in a roundabout fashion, and yet a real resistance, a reduction in the conducting substance of a rod, so that no portion, except that close to the surface, can take any part in the conduction of these rapidly alternating currents or discharges. It must naturally be better, therefore, not to make a lightning conductor of solid rod, but to flatten it out into a thin sheet, or cut it into detached wires; any plan for increasing surface and spreading it out laterally will be an improvement.

Perhaps it may be as well to guard against one favourite misconception. It has long been known that static charges exist only on the surface of conductors, it has also long been known that ordinary currents flow through the whole section and substance of their conductors. It is now beginning to be known that alternating currents may be sufficiently rapid to traverse only the outer layers of conductors, and this last piece of knowledge is felt to be rather disturbing by those who have been accustomed to dwell upon the behaviour of steady currents, and seems like a return to electrostatic notions, and an attempt to lord it over currents by their help. But the first and third facts mentioned above—the behaviour of static charges, and the behaviour of alternating currents—are two distinct facts, independent of each other; not rigorously independent perhaps, but best considered so far ordinary purposes of explanation.

We have thus mentioned two causes of obstruction met with by rapidly oscillating currents trying to traverse a metal rod. First, there is the direct inertia-like effect of self-induction to be added to the resistance proper; the resulting quantity being called by Mr. Heaviside "impedance," to distinguish it from resistance proper. For there is a very clear distinction between them; resistance proper dissipates the energy of a current into heat, according to Joule's law, impedance obstructs the current, but does not dissipate energy. Impedance causes tendency to side flash, resistance causes a conductor to heat and perhaps to melt. The greater the resistance of a conductor, the more quickly will the energy of a discharge be dissipated, its oscillations being rapidly damped; the greater the impedance of a conductor, the less able is it to carry off a flash, and neighbouring semi-conductors are accordingly exposed to the more danger. Resistance is analogous to friction in machinery, impedance is analogous to freely suspended massive obstruction, in addition to whatever friction there may be. To slowly changing forces friction is practically the sole obstruction, to rapidly alternating forces inertia may constitute by far the greater part of the total obstruction, so much the greater part that friction need hardly matter.

This is a fairly accurate popular statement of the direct way in which self-induction aids resistance proper in obstructing an alternating current. But in addition to these considerations there is that other indirect way which we have also mentioned, viz., the fact that conduction of alternating current may be confined to the surface of a rod or wire if the alternations are rapid enough. This cause must plainly increase total impedance, for the total channel open to such a current is virtually throttled, as a water pipe would be throttled by a central solid core.

But which part of the total impedance does it affect? Does it increase the resistance part or the inertia part? In other words, does this throttling of a conductor act by dissipation of energy or by mere massive sluggishness? Plainly, it must act like any other reduction of section, it must increase the resistance, the dissipating power of a conductor, the heating power of a current. Hence the resistance of which we have spoken as entering into the total impedance has by no means the same value as it has for steady currents, and as measured by a Wheatstone bridge. It is a quantity greater—possibly much greater—than this, and in order to calculate its value, we must know not only the sectional area and specific conductivity of the conductor but also the shape of its section and the rate of alternation of the current to be conveyed.

TAPE V. ROD.

We may here note a vigorous controversy, or difference of opinion, between Faraday on the one hand, and Sir W. Snow Harris on the other. Faraday was often consulted about lightning conductors for lighthouses, and consistently maintained that sectional area was the one thing necessary, weight per linear foot, and that shape was wholly indifferent. Harris, on the contrary, maintained that tube conductors were just as good as solid rods, and that flattened ribbon was better still. Each

is reported to have said that the other knew nothing at all about the matter. Of course we know that Faraday was thinking of nothing but conduction, and conduction for steady currents. Harris had probably no theoretical reason to give, but was guided either by instinct or by the result of experience. I think we shall have to admit that, in this particular, Faraday was wrong and Harris was right. The following experiment may serve to illustrate the point further.

I take two copper conductors of the same length and approximately of the same weight, but one of them in the form of wire, the other in the form of ribbon, and I use them successfully as an alternative path. The knobs at A being fixed at two centimetres apart, the B knobs were adjusted until the spark sometimes chose the air gap, and sometimes the alternative conductor. (See Fig. 1 or 2.) The critical B spark length was then:

	Millimetres.
With the wire as alternative path	8.36
With the ribbon " " " " " " " " " " " "	6.26
" wire " " " " " " " " " " " "	8.45
" ribbon " " " " " " " " " " " "	6.95
" wire " " " " " " " " " " " "	8.21
" ribbon " " " " " " " " " " " "	6.06

Very distinctly showing the advantage of a flattened form of conductor over a mere round section.

The dimensions of the two conductors here compared are as follows—Wire No. 12 B W G, 218 centimetres long, weight 91.6 grammes. Ribbon 218 centimetres long and 6.4 centimetres broad, weight 88.7 grammes.

But, it may be said, have not experiments often been made as to the advantage of tape over rod forms of lightning conductor, with negative results? Yes, but the point usually attended to is the deflagration of the conductor. Mr. Preece, for instance, with Dr. De la Rue's battery, found ribbon and wire equally easy to deflagrate by the discharge. But we are not examining which form of conductor is least liable to be destroyed by a flash; probably there is not much to choose between one form of section and another, for there is no time for surface cooling—we are examining which form will carry off a charge most easily, and with least liability to side-flash; and here thin ribbon shows distinct advantage over round rod.

IRON v. COPPER.

You remember we have found that a rod of iron carries off a discharge more satisfactorily than a rod of copper. It would seem as if the poorer conducting qualities of iron enabled the discharge to penetrate deeper, and so to make use of a greater thickness of skin.

But everyone will say—and I should have said before trying—Surely iron has far more self-induction than copper. A current going through iron has to magnetise it in concentric cylinders, and this takes time. But experiment declares against this view for the case of Leyden jar discharges. Iron is experimentally better than copper. It would seem, then, that the flash is too quick to magnetise the iron; or else the current confines itself so entirely to the outer skin that there is nothing to magnetise. A tubular current would magnetise nothing inside it. Somehow or other the peculiar properties of iron, due to its great magnetic permeability, disappear.

I do not believe anyone could have expected this result. Possibly Lord Rayleigh might have predicted it, and perhaps Mr. Oliver Heaviside. It would scarcely become me to express admiration for the work of so great a master of science as Lord Rayleigh (though, parenthetically, I may mention that I feel such admiration in the highest degree), but I must take the opportunity to remark what a singular insight into the intricacies of the subject, and what a masterly grasp of a most difficult theory, are to be found among the eccentric, and in some respects repellent, writings of Mr. Oliver Heaviside. I cannot pretend to have done more than skim these writings, however, for I find Lord Rayleigh's papers, in so far as they cover the same ground, so much pleasanter and easier to read; though, indeed, they are none of the easiest.

Can this suggestion with regard to iron be examined and verified or disproved in some other more direct way?

It is easy to try another experiment. I have here two conductors made of tinfoil, each is made of a long slip of tinfoil, about 3 in. broad, and 21 ft. long. One is zigzagged backwards and forwards, with the interposition of three thicknesses of paraffin paper between each zigzag to insure insulation, so as to abolish self-induction as far as possible. This I call the tinfoil zigzag. The other is coiled spirally on a glass tube—again with the interposition of paraffin paper—so as to give as much self-induction as possible. This I call the tinfoil spiral. A bundle of fine iron wires—the core of an induction coil, in fact—can be introduced into this glass tube, or withdrawn at pleasure. The resistances of these conductors, measured in the ordinary way, are—614 ohms for the spiral, and 708 ohms for the zigzag. They were intended to be alike.

The connections being made as in Fig. 1, one or other of these tinfoil conductors is used as the alternative path, L, with this result:—

The length of the A spark being 7.3, the critical spark-length

at B, when sparks sometimes passed and sometimes failed, was 11.1 when no alternative path was provided. When the tinfoil zigzag connected the outside of the jar instead of the wire, L, it was not possible to get a B spark till the distance was shortened to 0.6, when this was replaced by the tinfoil spiral, the critical B spark-length rose to 6.4. The iron bundle was now inserted in the spiral, and the experiment tried again. The B spark-length remained 6.4. The iron made no perceptible difference whatever.

Here is a magnetic time-lag raised to an extreme. Prof. Ayrton tells me they have noticed the permeability of iron begin to diminish with very quick alternations. Here it is becoming virtually no bigger than that of air. It may be said that the iron fails to get magnetised because of the opposing action of the inverse "Roussault" currents induced in it, just half a period behind the inducing currents. I thought this would be so, of course, with thick rods of iron, but with a bundle of thin wires I felt doubtful. Lord Rayleigh, however, thinks these induced peripheral currents competent to explain magnetic time-lag in every case, and I can have no doubt that he is right. Whatever the explanation, the fact of time-lag in iron is patent. Yet there is something strange about it, for that a steel knitting-needle can be magnetised by discharging a Leyden jar round it is mentioned in every text book, and (what does not necessarily follow) it is certainly true. There are points here requiring further examination.

However, if it turns out to be true that an iron rod does not get magnetised by the passage of a rapidly alternating current, it may be held a natural consequence of the fact that such currents flow mainly in its outer surface, and that such tubular currents have no magnetising power on anything inside them.

The magnetisability of iron is no objection to its employment in lightning conductors. Its inferior conductivity is an advantage in rendering the dash slower, and therefore less explosive. Its high melting point and cheapness are obvious advantages. It is almost as permanent as copper, at least, when galvanised; and it is not likely to be stolen. I regard the use of copper for lightning conductors as doomed.

EXPERIMENT OF THE BYE-PATH.

We have seen that a conductor is more efficient in carrying off a discharge and preventing side-flash, in proportion as its self-induction is lessened—say, by spreading it out into a thin sheet, or cutting it up into a number of wires, or otherwise. But no conductor is able to prevent side-flash altogether, unless it is zigzagged to and fro so as to have practically no self-induction; in that case the side spark is nearly stopped. But so long as a conductor is straight (and a lightning conductor must, of course, be straight), so long will there be some tendency to side-flash, however thick it be made. It may be a foot or a yard thick, and yet not stop it.

One may easily try the following experiment—Take a yard of stout brass or copper rod an inch thick, arrange it in the path of a Leyden jar discharge, and then arrange, as a sort of bye-path or tapping circuit, some very fine wire, such as Wollaston platinum wire (Fig. 3). It may seem absurd for any portion of the discharge to leave the massive rod and take the hair-like wire by preference, especially if an air-gap exists at A or at B, or at both. Nevertheless, a portion *does* choose the fine wire path, and you get a little spark at A or at B about a sixteenth of an inch long. One may vary the experiment by trying to get a shock by holding two different parts of a thick copper rod through which a discharge is passing. The mere difference of potential between conductor and earth must, of course, be avoided. It is not easy to get an appreciable shock from a few yards of very stout conductor; still, it can be done. Holding two points of a stout open spiral, consisting of about five yards of No. 1 copper wire, connected to earth, a faint shock can be felt with wetted hands whenever a Leyden jar is discharged through the copper. No doubt with a very large condenser the shock would be quite noticeable; and a man touching a lightning conductor, however well earthed, might perhaps receive a shock sufficient to kill him. At all events, I should not care to try the experiment with a real lightning flash.

EXPERIMENT OF THE SIDE-FLASH.

Let me illustrate the tendency to side-flash by a more directly applicable looking experiment. Fig. 4 shows a couple of tin-plates or tea-trays fixed a foot or so apart, one earthed, the

other insulated. They obviously represent one a charged cloud, the other a layer of thoroughly good conducting earth. A lightning conductor, B L, is provided; L consisting of a considerable length of stout copper wire or rod. At C a possible side path is provided, so that, if the flash chooses, some of it can spit off through an inch or so of air, and through an interposed resistance, R, to earth. A side flash, C, is found to occur unless the sparking distance is made too great, and the effect of increasing R is not to stop the side flash, but to weaken it. Thus, even with the liquid megohm of nearly a megohm at R, an inch spark still passes at C for every flash at B, though the C spark is now very weak.

How can this tendency to side-flash be further diminished? At the end of the last lecture I hinted at a partial remedy—elasticity. To stop a pipe full of water from being burst by a blow given to the water, you will make the pipe elastic. An elastic cushion will ease off the violence of the shock of a water-rain.

Electric inertia was known by the other name of self-induction; electric "elasticity" is known by the other name of capacity. Increase the capacity—not the thickness or conducting power, but the electrostatic capacity of your conductor—and it will be able to carry off more.

This phrase, "the capacity of a conductor," when used by the old electricians, commonly signified merely its conducting power, this being the sole thing most of them thought of; but using it in its modern signification let us see what advantage is to be gained by increasing the capacity of a conductor—say, by connecting to its two ends the coatings of a Leyden jar.

Take the No. 18 wire round the room and use it as an alternative path, as in Fig. 1, first without a jar connected to its ends, then with a jar. Length of spark at A, 5.35 tenths of an inch; corresponding critical B spark length:

Iron wire without jar, 6.5;

Iron wire with jar, 5.0.

Not a very great difference. Not so great a difference as would be gained by diminishing the self induction by flattening the wire out in foil. Still, it is in the right direction, and we see what we have to do—diminish self induction as far as possible, and increase capacity whenever convenient. One may also try the experiment by attaching a jar to the conductor B, in Fig. 4. The side flash, C, is somewhat shortened.

But of an actual lightning conductor, how is it possible to increase the capacity? There is no sense in surrounding it with an earth tube, because that, after all, would only act as an additional conductor, and might as well be so considered from the first. Neither does a great series of polarisable voltmeter plates seem a feasible suggestion. No; the only practicable plan is to expand it over as much surface as possible. A lead roof, for instance, affords an expansion of fair capacity which may be easily utilised; and there should be as little mere rod projection as possible before some extent of surface begins. Flat sheet for chimneys is better than round rod—it has at least some more capacity and much less self-induction.

For tall isolated chimneys I would suggest a collar of sheet metal round the top and at intervals all the way down; or a warp of several thin wires instead of a single rod, joined together round the chimney by an occasional woe; or any other plan for increasing capacity and area of surface as much as possible.

LIABILITY OF OBJECTS TO BE STRUCK.

Now, try experiments on the liability of things to be struck. Is a small knob at a low elevation as liable to be struck as a large surface at a higher elevation? Is a badly-conducting body as liable to be struck as a well-conducting one? In other popular words, does a good conductor "attract lightning"?

In answering this question experimentally, we must draw a careful distinction between the case of a flash occurring from an already charged surface, which has strained the air close to bursting point before any flash occurs, and the case of a flash produced by a rush of electricity into a previously uncharged conductor too hastily for it to prepare any carefully-chosen path by induction. The two cases are: 1st, steady strain; 2nd, impulsive rush. Take them separately.

FIRST WITH STEADY STRAIN.

First, an experiment on the liability of things to be struck when the air above them is in a state of steady strain gradually increased. I take the two tin plates, arranged one over the other, and stand between them three conductors, one ending in a large knob, a second ending in a small knob, and the third ending in a point (Fig. 5).

The experiment consists in working up the charge of a jar attached to the top plate until discharge occurs, and in adjusting the three conductors so that they may be indiscriminately struck. One finds that the point, even when very low, prevents discharge altogether. It may indeed be too low to be effective, or, again, it may be insufficient to cope with the supply of electricity, but we see here the well-known function of a point—prevention of discharge. Remove or cover up the point now, and attend only to the large and small knobs. If the knobs are negative and the plate above them positive, brush dis-

charge goes on from the knobs, and it is not easy to get a long flash, but by reversing the connections the tendency to brush is greatly lessened, and we now get flashes some three or four inches long. But always to the small knob. The small knob has to be pulled down about three times as far from the charged surface as the big knob is before it ceases to protect the big knob, and the latter is then for the first time struck. This occurred, for instance, when the distance of the big knob from the top plate was 9, and the distance of the small one 29 $\frac{1}{2}$ (tenths of an inch). They were then either of them struck indiscriminately. If the little knob was any taller than 29 $\frac{1}{2}$, it alone was struck.

Now, what is the effect of resistance upon the protecting power of the point or small knob? Scarcely any. Instead of connecting the small knob direct to the bottom tray, connect it through the liquid megohm, R, and it gets struck just as easily as before.

FIG. 5.

Here are distance readings when they got struck with equal ease. Large knob distance, 7.5; small knob distance, with high resistance, 22.0. The point protects both up to distance 60.0, until covered up by a thumb.

Thus, the flash actually prefers to jump three times as much air, and encounter a megohm resistance, rather than take the short direct path offered by the bigger knob. The sizes of the knobs in this experiment are—1.27 in. diameter for big knob, and .56 in. for small knob.

Of course, the cause of this is well known. It is merely that the air breaks down at the weakest point—viz., on the surface of one of the knobs, and the tension on the small knob is much greater than that on the big one for a given difference of potential. The fact that the discharge begins in the air above the conductor explains why it is that adding resistance—even enormous resistance—to a conductor makes no difference to the length of the spark which strikes it. The path is prepared inductively in the air, and the resistance of the path which the discharge must ultimately take makes no difference, provided it is not so nearly infinite as to prevent the free adjustment of the static charges and inductions set up as the machine is worked. But though high resistance makes no difference to the length of the spark, it does affect its noise and violence. The discharge striking the small knob has now only a soft velvety noise. Its energy, or heating effect, is much the same, but its suddenness, and, therefore, its noise and violence, are enormously lessened.

This water resistance is equivalent to a shocking bad earth, and its effect is, we see, to make the spark gentle. But it is an evident advantage to have a discharge take this quiet and manageable form. The worse a conductor is, the quieter will be the flash; and, up to a certain limit, it will protect just as well apparently. Hence, surely, a bad earth is an advantage. But wait a bit; we have not yet considered the other case—the impulsive rush.

SECOND, WITH IMPULSIVE RUSH.

Let us now modify the experiment to try the second form of the experiment—the impulsive rush.

FIG. 6.

Fig. 6 shows the connections. There is no difference of potential between the trays up to the very instant of discharge. The jars gradually charge up (they stand on the same wooden table), and ultimately discharge at A. A violent rush then takes place into the two plates, and the conductors between are struck. Adjust them till they are all struck with equal ease, as before; we find the conditions utterly different. No longer does the small knob protect the taller big knob; no longer does the point exert any special protective influence. All three bodies—large knob, small knob, point—are equally liable to be struck if at the same height, and no one is more liable than another; simply the highest is struck if they are at all equally conducting. It is easy to get all three struck at once. Now make one bad conducting, and its protective virtue is gone. Putting the liquid megohm into any one of the three conductors, and that one is no longer struck. It ceases to protect the other two, even if taller than they, nay, even if it be raised so as to touch the top tray, thus establishing direct conducting communication of a poor kind between cloud and earth, still

next to none of the flash chooses that path, and the other two conductors get struck with apparently just the same ease as before. This is the real objection to a bad earth; it cannot protect well against these sudden rushes.

Sudden rushes are liable to occur, the clouds spark first into one another, and then, as a sort of secondary effort or back kick, into the earth. For instance, two clouds, one above the other; the top cloud sparks into the lower, and this at once overflows to the earth. In these cases the best conducting and highest objects are struck, quite irrespective of any question of points and knobs. Points are no safeguard against these flashes, as you see. The point gets struck by a vivid flash, exactly of the same character as that which strikes one of the knobs; it has no time to give brushes or glows, its special efficacy in preventing discharge exists only in the case of steady action, where the path is pre-arranged by induction. In the case of these sudden rushes, the conditions determining the path of discharge are entirely different. No doubt they have to do with what is called the "time-constant" of the various conductors.

EXPERIMENT OF THE RECOIL KICK.

It will have been noticed that in the experiment of Fig. 1, the spark obtained at B is longer than the spark at A. And the question arises why this should be so. Plainly, what is happening is this: The discharge at A sets up electrical oscillations, and the charge of the jars is rapidly reversed. The difference of potentials of the inner coats changes from, say, $+V$ to nearly $-V$, and back again; the difference of potential of the outer coats changes, therefore, from 0 to nearly $2V$, and hence the B spark may be expected to be nearly twice as long as the A spark; and so it is.

These electrical oscillations are of considerable interest, and have sundry practical bearings; let us proceed to make them more conspicuous. Fig. 7 shows a couple of long leads, L and L', reaching round the room (No. 18 wire in two 95ft. lengths was actually employed), insulated from one another and from the earth, but attached to the two poles of a machine, the machine having also a couple of Leyden jars attached to it in the customary manner when supplied by the maker. A discharger, B, can be arranged to bridge the gap between these leads, either near the machine, as B₁, or about the middle, as B₂, or at the far end, as B₃. Now, of course, sparks can be obtained either at A or at any of the B knobs, and all about the same length; but supposing the A knobs to be brought nearer than the B knobs, the spark would be expected to occur at A only. Nevertheless, on trying the experiment, one finds that every time a spark occurs at A, a longer spark occurs at B; it is, as it were, precipitated with a rush; and the longest spark of all is obtainable at the far end—viz., at B₃.

Here are some figures, in the obtaining of which, however, for convenience of manipulation, the B length remained constant in each position, and the least length of the determining spark, A, was the thing observed:

Nearest position.			
Spark length A	3.20	4.15	5.12
Corresponding spark length B ₃	3.22	4.80	6.18
Middle position.			
Spark length A	1.92	2.37	2.70
Corresponding spark length B ₃	3.22	4.80	6.18
Farthest position.			
Spark length A	1.60	2.2	2.45
Corresponding spark length B ₃	3.22	4.80	6.18

The electricity in the long wires is surging to and fro, like water in a bath when it has been tilted; and the long spark at the far end of the wires is due to the recoil impulse or kick at the reflexion of the wave. Evidently, there are some quantitative relations to be specified here, and there will be some best capacity of the jars corresponding to a given length of conductor, and to a given arrangement of main discharge current A. The nearer the length of the conductors corresponds to a half wave length, or some multiple of a half-wave length of the oscillations produced by the discharging jars, the more perfect will be the synchronism between the pulses, and a longer recoil kick may be expected. The arrangement may, in fact, be compared to a resonant tube excited by a tuning fork or reed, to Melde's experiment with vibrating strings, or to any other case of forced vibration.

The following numbers will just serve to show some difference of effect caused by different sizes of jars. Using two pint jars

in series, and fixing the A spark at 4.5, the B₃ spark at the far end just ceases when the knobs are pulled out to 7.8. But, replacing the pint jars by gallon jars, the B₃ spark does not cease till the knobs are separated to 10.9, the corresponding spark in the position B₁ being only a trifle longer than the A spark—viz., 4.7.

It is not to be supposed, however, that by increasing the capacity of the jars still farther, a still better effect will be obtained; for on replacing the two gallon jars by the very large condenser of alternate glass and tinfoil sheets, we find the spark at B₃ fails when the knobs are only 5.9 tenths of an inch apart; the length of the A spark remaining 4.5, as before.

There is, as I say, a quantitative relation; and it is a relation which the modern theory of electricity makes known. I cannot go into it here, but I may just say that, very approximately, the wave length of the electrical oscillation of a discharging jar is 2π times the geometric mean of the static capacity of the jar and the electro-magnetic inertia of the discharger.

The capacity of the two gallon jars in series (this being the capacity which gave the best result with 95ft. of leads) was about .002 microfarad, or, say, 1,800 centimetres; hence, supposing the wave length of their discharge through the A knobs to be something like 190 or 200ft. (twice the length of the leads), we should calculate the self induction of the circuit formed by the jars, short connecting wires, and A knobs, as something like five metres, which is a reasonable enough value.*

Repeating the experiment, Fig. 7, with the two gallon jars in series, but insulated this time from the earth, a still longer spark at B₃, the far ends of the long wires, can be obtained—viz., A = 4.5, B₃ = 14; and even when the knobs of the discharger are separated beyond this distance, a brush still passes between them for every spark at A.

Removing the discharger altogether, and making the experiment in the dark, a very interesting effect is seen; the further end of each wire glows with a vivid brush light, showing the exceedingly high potential to which they are raised by the recoil. I do not see the effect with thick No. 1 wires, but with No. 18 wires it is very marked. The glow on each of the two wires is independent of the position of the other; thus, if the connections are made so that the wires run opposite ways right round the room from the machine, the distant end being insulated, it is still the end of each furthest from the machine that glows, although they are separated from one another, for most of their length, by the whole width of the room. With the two gallon jars the wires glow over fully three-fifths of their entire length. With jars of much larger or much smaller capacity the length of glow is conspicuously less.

Connect a small pint jar to the ends of the wires, and all these effects cease. The increase of static capacity reduces their potential below the brushing point. Arranging the jar so as to leave an air space between it and one of the wires, a spark passes into it at each A spark, but the jar is not the least charged afterwards—proving that the spark is a double one, first in and then out of the jar, a real recoil of a reflected pulse. Hence it is also that the appearance of the brush is the same on the two wires—one is not able to say which is the positive and which the negative wire, for each is both.

EXPERIMENT OF THE SURGING CIRCUIT.

What seemed to me, when I first made it, a curious illustration of these electrical surges or oscillations going on in a conductor which is being suddenly discharged at one end, is afforded by the following extremely simple experiment.

Attach one end of a long insulated wire to the machine, and connect the other pole of the machine to earth. Jars connected up also to the machine do no harm, but they are unnecessary. The wire now practically constitutes one coating of a condenser, of which the walls of the room are the outer coat. The wire is made to form a nearly closed circuit, and its further end brought within an inch or so of the near end, as at B (Fig. 8).

Under these circumstances one would at first sight say that a spark at B was absurd, for the two knobs are metallically connected through a stout conductor, which may be No. 1 wire, and not necessarily many yards long. Nevertheless, it will be found that sparks at B can be obtained quite as long, though not quite as strong as those at A. Every A spark is accompanied by a B spark, unless, of course, the knobs are too far separated.

* Since the delivery of the lecture, a great number of quantitative observations on these lines have been made. Evidence of electro-magnetic waves thirty yards long has been obtained. I expect to get them still shorter.

One may surmise that it is the static charge on the distant portion of the conductor which, having to rush toward A, prefers the short path, B, instead of the longer path *via* the wire. But this is not the whole account of the matter, as can be shown by interposing high resistance in the conductor at various points; say, at the places 1, 2, 3, or 4 (Fig. 8). Introducing a quarter of a megohm at the point 1 or at 3 weakens the B spark very much, and apparently about the same whether it be at 1 or at 3; the strength (i.e., the noise and appearance) of the A spark remaining much the same. Introducing a high resistance at the point 4, weakens both the A and the B sparks. Introducing a high resistance at the point 2, leaves both sparks pretty much as strong as they were without it.

The spark at B is caused by electrical oscillation—a surging of the charge of the wire to and fro like water in a pipe. One might liken it to an elastic pipe pumped very full of water, and its end closed with spring valves. If, then, one end is suddenly opened and shut, a pulse is transmitted through the pipe, which may force open the valve at the far end and let some water escape.

It is these electrical oscillations, I doubt not, which account for the long spark obtained by the use of a "Winter's ring."

This last experiment, Fig. 8, however it may be explained, has an obvious application to the question of connecting roof gutters to lightning conductors. It is most desirable to connect them, but both ends should be connected. If only one is connected, the far end is very likely to spit off a flash.

Again, we see how, when a flash strikes a system, the electricity goes rushing and swinging about everywhere for no apparent reason, just as water might surge about in a bath or system of canals into which a mass of rock had just dropped, splashing and overflowing its banks. Just so with electricity. Bell wires, gas pipes, roof-gutters, conduct side-flashes in a way most puzzling to the older electricians; and thus gas may get ignited in the most unexpected places, and passengers in a train may feel a shock because a charge has struck the rails. In powder magazines it is apparent how dangerous this lawless sparking tendency may be, for even the hinge of a door may furnish opportunity for some trivial spark sufficient to ignite powder. By no means, it seems to me, should high roofs be stuck up to invite a flash to such places. Build them, or line them, with connected iron, barb them all over the roof, connect them to the deep ground in many places, and I don't see what more can be done.

EXPERIMENTS ON OVERFLOW OF JAR.

Another way of making these electrical surging more conspicuous is by their effect in causing a jar to overflow, i.e., to spark round its edge. The overflow of a common jar is, in fact, very like a lightning flash, for it is a discharge direct between two coatings. That is just what a lightning flash is. There is ordinarily no conductor present except the two coatings, the clouds and the earth. I found a curious remark in Franklin* about the overflow or fracture of Leyden jars. He found that when one broke from overcharging, a great number went together, and that the spark in the ordinary circuit did not fail. He was led by this observation to doubt if the breakage of the jar was really due to a discharge of the electricity through it, and he surmises that it may be due to a sudden expansion of air-bubbles in the interior, suddenly relieved of the strain.

No doubt he is wrong there, but the observation of the facts is good and noteworthy. We will repeat the experiment. It is not necessary to burst the jars; overflow round the edge is just as good, and cheaper. The overflow experiment can be put into a variety of forms, perhaps it will be sufficient if I show the simplest.

Fig. 9 shows the arrangement. It consists in nothing but establishing the connection between the machine and one or both of the coatings of a jar through a long wire instead of a short one as usual. If one connects the jar, C, by the dotted line, it does not overflow until the spark-length A is very great, but with a long lead, L, to make the connection, a very short spark at A will cause the jar to overflow or discharge round its edge.

Here are a few numbers. The jar is one of the gallon jars, with the glass fully three inches above the tin-foil, so that, when it overflows, the spark has to strike along fully six inches of glass. When L is the thick No. 1 copper circuit round the room the jar overflows every time an A spark occurs, even though the length of this A spark is only 64 of an inch. Short circuit out the long lead, as shown by the dotted line, and the jar refuses to overflow until the A spark length has been increased to 1'7; and when it does overflow now the violence is very considerable. Remove short-circuit again, and the jar overflows in ever so many places at once with great violence, a perfect cascade of flashes leaping round the edge. Bring the A knobs nearer together, and the overflow does not wholly cease till their distance apart is again 62. On another occasion one got for the A spark-length sufficient to cause overflow of jar:—

56 with the long lead,
17 with an ordinary short wire.

With a small pint jar, and a less height of glass above its coatings, I took the following readings. Length of A spark sufficient to cause overflow—

67 with iron wire round room,
52 with copper " "
1'40 with short circuit.

Fig. 10 shows very well, in a diagrammatic fashion, the effect of long leads in causing a jar to overflow, or, of course, to flash, if the glass edges are too tall for the thickness and homogeneity of the glass to stand.

Fig. 10

A are the machine terminals, B those of a discharger, and J_1 and J_2 are two jars connected up by fairly long leads. Now, of course, sparks may be obtained either at A or at B, one as easily as the other, and one of the jars is liable to overflow, but not both. It is the jar J_2 which overflows when a spark occurs at A. It is the jar J_1 which is made to overflow by a spark at B. It might be thought that if the B knobs were fairly near together, a spark at A might precipitate a spark at B, instead of making J_2 overflow; but it is not so. The event is not, in fact, impossible by any means, if the B knobs are pretty near together, but it is easier for the jar to overflow by direct discharge between its coatings over a space of some 6 in., than it is for it to discharge through the wire and rods of the discharger, and an air space of an inch, or even less. It is not easy to help a jar to overflow by discharging tongs. Even a lead of conducting wire is a great obstruction to the passage of the flash; it greatly prefers direct discharge through air unobstructed by the self-induction confinement of a conductor.

This is also illustrated by the extraordinary length of insulating surface which is found necessary in the Leyden jars supplied to Holtz and other such machines, and by the fact that such jars often flash even over a foot instead of through a few inches of air space led up to by the proper discharging-knobs. Though indeed, it must be noticed, as it was by Franklin, that the overflow of a jar by no means necessarily robs the proper circuit of its flash. The two things occur together. It is usually the spark which causes the overflow. Perhaps one may say that the case of discharge direct between coatings without any conductor, accounts in some measure for the extraordinary length and unexpected paths of some lightning flashes.

These electrical oscillations and overflows, which it is thus easy to set up in a charged conductor, manifestly explain what is known as the "return stroke." I pointed out in Lecture I that the ordinary explanation of the return stroke, the recovery of electrical equilibrium disturbed by static induction, was by no means able to account for effects of the least violence, but this fact, that a discharge from any one point of a conductor may cause such a disturbance and surging as to precipitate a much longer flash from a distant part of it, at once accounts for any "return stroke" that has ever been observed.

It is for this reason that I think it possible a tall chimney or other protuberance in one's neighbourhood may be a source of mild danger; inasmuch as if it is struck it may be the means of splashing out some more discharges to other smaller protuberances, which otherwise were beyond striking distance. It is in this way, also, that I imagine multiple flashes, such as those referred to in Lecture I, are produced. I liken them to the cascade of flashes rushing over the sides of a jar, when connected up with a long lead, and when the A spark is pretty long.

EXPERIMENT OF THE GAUZE HOUSE.

Finally, we have to ask, Is it possible for the interior of a thoroughly enclosed metal room to be struck, or, rather, can a

FIG. 11.

small fraction of a lightning flash find its way into a perfectly enclosed metal cavity; for instance, a spark strong enough to ignite some gun cotton in a metal-covered magazine which might happen to be struck?

It is not easy, but it can be done, at least under such conditions as are likely to obtain in practice it can be done. My friend, Mr. Chattock, to whom I am indebted for much kindly assistance and suggestion, has made the experiment in the form shown in Fig. 11.

* "Franklin's Works, by Sparks, 1840., vol. v., page 475.

A metal gauze cylinder, with tin plate ends, has a couple of conductors, one soldered to each end, protruding into the interior, so as to approach very near each other, and these are the conductors put into the path of the discharge. If both conductors are entirely enclosed in the metal chamber, we have not yet succeeded in getting a spark between them, but if either of them protrude any portion of their length outside the chamber, then sparks in the chamber can be obtained.

In Fig. 11 the conductor, N M B, is shown thus protruding, penetrating the chamber through a small glass tube near M, but soldered to it near N. E F is a movable arm or radius, making contact with this conductor. If contact is made near M, it takes a very strong A spark to give any spark at B inside the gauze cylinder; but as the contact from F is shifted towards N, it becomes very easy to get a small spark at B.

The application of this to powder magazines is that if any conductor (like a gas-pipe) pass out of the building before being thoroughly connected with its walls, it is possible for a spark to pass from something in the interior of the building to this conductor whenever a flash strikes the building. We thus find that the complete and certain protection of buildings from lightning is by no means so easy a matter as the older electricians thought it.

In many cases we may be content to fail of absolute security, and be satisfied with the probable safeguard of a common galvanised iron rod or rope. But for tall and important buildings, for isolated chimneys and steeples, and for powder magazines, where the very best arrangement is desirable, what is one to recommend? I prefer to call attention to principles rather than to advocate any particular nostrum; but inasmuch as my present opinion is not likely to carry any undue weight, there is no harm in my saying that I see nothing better than a number of lengths of common telegraph wire. I think a number of thin wires far preferable to a single thick one; and their capacity must be increased, when possible, by connecting up large metallic masses, such as lead roofs and the like. But the connection should be thorough, and made at many points, or sparks may result. Balconies, and other prominent and accessible places, should not be connected.

The earth should be deep enough to avoid damage to surface-soil, foundations, and gas and water mains. As to the roof, I would run barbed wire all round its eaves and ridges, so as to expose innumerable points, and the highest parts of the building must be specially protected; but I would run no rods up above the highest points of the building, so as to precipitate flashes which else might not occur, in search for a delusive area of protection which has no existence.

The conductors must not be so thin as to be melted or deflagrated by the flash; but really melting is not a very likely occurrence, and even if it does occur, the house is still protected; the discharge is over by the time the wire has deflagrated. The objection to melting is twofold. First, the red hot globules of molten metal, which, after all, are not usually very dangerous out of doors; and, secondly, the trouble of replacing the wire. I should be content to put up a great number of telegraph wire conductors, and wait till one is melted, before thinking too much of the likelihood of such an occurrence. The few instances ordinarily quoted of damage to lightning conductors by a flash do not turn out very impressive or alarming when analysed.

In conclusion, I trust that the men of experience in these matters who are present will consider the facts and suggestions I have brought forward as objects worthy of attention and further inquiry, and will study them in the light of their experience.* But as to the quick receipts and dogmatic statements which I may incidentally and without authority have provisionally given, there is no need for me to ask practical men to treat these with the contempt they no doubt deserve.

PROVISIONAL PATENTS, 1888.

JUNE 16.

8751. **An improvement in the Wheatstone automatic system of telegraphic transmission by which it is adapted for use on submarine cables in connection with the "siphon recorder" and "mirror" systems.** Thomas James Winant, Watervliet, N.Y.
8765. **Improvements in holders for incandescent electric lamps.** Walter Rowbotham and William Fox, 39, Lever street, Manchester.
8772. **Improvements in electrical switches.** Walter Rowbotham and William Fox, 39, Lever street, Manchester.

* At the second lecture I learnt that some experiments on lightning protectors, something like those of note on "the alternative path," had been made previously by Prof. Hughes and M. Gallenon addressed to telegraph engineers. Also I find that Dr. Hertz has made experiments on electric oscillations very like those of mine on "the singing circuit" (Wied. Ann., 1887). In a subsequent communication I hope to notice some of the observations of Prof. Hughes.

8784. **Improvements in systems of electrical supply.** Frederick Wilhelm Andersen and John Forwood Tafe, 47, Lincoln's inn-fields, London.

8809. **Improvements in electric switches.** Henry Harris Lake, 45, Southampton buildings, Mill Lane, Sigmund Hergmann, United States.

8814. **A new or improved magazine small-arm discharged by electricity, and cartridges for the same.** Alfred Treoby, 7, Staple Inn, Middlesex.

JUNE 16.

8836. **Improved safety electrical switch and fuse box combined.** George Joseph Filippett and George Herbert Alderton, 40, Gloucester road, Brighton, Sussex.

8864. **An electric tell-tale or counter mechanism.** David Alfred And, 166, Fleet street, London.

JUNE 18.

8871. **Improvements in electrical switches, commonly called electric bell pushes or presses.** James Insole Ryder, 2, North Parade, Matlock Bath, Derbyshire.

8905. **Improvements in electric batteries.** Hector Lahousse and Co. and Charles Colie, of the said firm, 47, Lincoln's inn-fields, London.

8912. **An electric meter for registering or recording electricity.** Henry Hanson, 47, Castle street, High street, Battersea, S.W.

8919. **A new or improved type of electric cable, specially applicable for high tension alternating currents, and methods of, and apparatus for, manufacturing the same.** James Greve Lortz, Norfolk House, Norfolk street, London, W.C. (La Société d'Exploitation des Câbles Electriques, Systeme Barthold Harel et Compagnie, Switzerland).

8920. **A new or improved type of electric cable, specially applicable to long distance underground and submarine telephony.** James Greve Lortz, Norfolk House, Norfolk street, London, W.C.

JUNE 19.

8950. **Improvements in applying electrical traction to pleasure, sporting, and business purposes.** Charles Barnard Burton, 32, Holborn hill, Higher Trammere, Birkenhead.

JUNE 20.

9032. **Improvements in electric arc lamps.** Walter Russell Mortimer and James Holloway, 28, Southampton buildings, Chancery-lane, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

MAY 17, 1887.

7185. **Improvements in electro-propulsive motors and in the application thereof to wheeled vehicles or rolling stock.** William Hopkin Akester, 57, Chancery lane, London.

JULY 20, 1887.

- 10,177. **Improvements in the manufacture or treatment of porous pots, plates, or partitions for electric batteries.** Edward Ludwig Mayer and Henry Liepmann, Norfolk House, Norfolk street, London, W.C.

AUGUST 20, 1887.

- 11,390. **Improvements in the manufacture of elements or plates for secondary batteries or electrical accumulators.** James Shannan Stevenson, 47, Lincoln's inn-fields, London.

AUGUST 22, 1887.

- 11,417. **Improvements in and connected with electrical connections with moving bodies.** Thomas Alexander Garrett, 80, Abingdon road, Kennington, London, W.

AUGUST 23, 1887.

- 11,502. **Improvements in dynamo-electric and electro-dynamic machines.** Edward Frederick Hermann Heinrich Lauckert, 28, Southampton buildings, Chancery-lane, London, W.C.

OCTOBER 11, 1887.

- 13,758. **Improvements in electrical apparatus especially applicable for use in dental operations.** Alfred Julius Gault, 323, High Holborn, Middlesex. (Elias Smith and Frederick Kumble, United States).

SPECIFICATIONS PUBLISHED.

1882.

4362. **Distributing electricity.** L. Gaulard and J. D. Galus. 8d. Amended specification.

1887.

4219. **Accumulators of electricity.** C. Desmazières. 8d. Amended specification.

1887.

5648. **Making and breaking electric circuits.** J. B. Holmes. 8d.

CITY NOTES.

Brazilian Submarine Telegraph Company. The traffic receipts of the Brazilian Submarine Telegraph Company for the past week amounted to £4,072.

Telephone Company of Austria. The Telephone Company of Austria, Limited, notify that coupon No. 7 of their 5 per cent. debentures due July 1 next, will be paid, less income-tax, on and after July 2, by Messrs. Martin and Co., 68, Lombard-street.

Western and Brazilian Telegraph Company. The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ending June 22, after deducting the fifth of the gross receipts payable to the London-Platino Telegraph Company, Limited, were £3,385.

Eastern and South African Telegraph Company.—The Eastern and South African Telegraph Company notify that the coupons due July 2, on their 5 per cent. mortgage debentures, will be paid on and after that date at the banking house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C.

South of England Telephone Company. The Directors of the South of England Telephone Company, at their meeting on June 21, decided to recommend a dividend of 1/2 per cent. on the ordinary shares capital for the year ending April 30 last, placing £500 to a reserve fund, and carrying forward £1 115. 0s. 8d., the dividend on the preference shares having already been paid.

United Telephone Co. The report of this Company for the year ending April 30 states that capital account will show that up to April 30, 1883, the sum of £263,876 has been expended upon the works in connection with the metropolitan district and instruments on royalty in the metropolitan district and subsidiary companies, being £35,695 more than the outlay shown in the last balance sheet. The revenue accounts (exclusive of metropolitan district royalties), show that the receipts of the Company from all sources properly attributable to the year have been £143,154, as against £130,704 in the preceding year, or an increase of £12,450, and the expenditure, including snowstorm, losses and allowances, £116,653 has been £73,519, as against £66,954, or an increase of £6,564. The working expenses for the year have been £35,725. 12s., as against £30,483 14s. 2d. for the preceding year, or an increase of £5,240. 17s. 10d. The balance of net revenue account is £68,697, of which amount the sum of £22,377 has been absorbed by the payment of an interim dividend at the rate of 10 per cent. per annum for the first half year ended October 31, 1887, and the Directors recommend a further dividend of 10s. per fully paid £5 share and 5s. per part paid share for the second half year ended April 30, 1888, amounting to £44,755, making a total dividend of 15 per cent. for the year, leaving a balance of £1,563 to be carried forward. A sum of

£14,375, being the amount received during the year as premiums on new shares, has been carried direct to the reserve fund.

Telephone Company. For a body of men so well paid as the Directors of the United Telephone Company are, they seem to know singularly little about the business of the Company. In December 1886 there was a snowstorm. In July of 1887 the Company's annual meeting was held. The chairman, Mr. James Brand, then said: "In addition to our expenditure for working expenses we have spent £11,000 in repairs and replacements caused by the damage done to the snowstorms, and we have put about £5,000 to a suspense account for liabilities in connection with the snowstorms which are possible turn-ups." No doubt here, evidently, that the whole loss had been provided for. But the deputy-chairman Mr. J. Stants Forbes, was quite emphatic. Speaking of the snowstorm "an unparalleled calamity," he called it "he said: 'I will advert only to the fact that a larger sum than £15,777, which seems to have been the cost of it, has been charged at once wholly to the revenue account.' Surely, if every ghost was laid, this snowstorm bogey might be considered under latches. But, no, not a lot of it. The balance sheet of the Company is just out, and our old friend, the snowstorm, figures for £15,653 and Good old snowstorm!—Financial News.

The International Engineering Company, Limited. Registered by Deane and Pattison, 52, Lincoln's Inn fields, W.C. Capital £5,000, divided into 5,000 shares of £1 each.
